uses individual load cells on a series of connected force platform tiles to quantify gait. No data exists that examines the performance of SRC using this device. **PURPOSE:** The purpose of this study was to evaluate the differences in center of pressure (CoP) performance during single-task (ST) and dual-task (DT) tandem gait within 24-48 hours post-SRC. **METHODS:** 18 Division I [SRC (age: 19 ± 1.00 yr. Male=7, Female=11)] and 18 nearly matched controls [CON (age: 19.88 ± 1.05 yr. Male=7, Female=11)] completed the vestibular ocular motor screening test (VOMS) and 3 trials of ST and 1 trial of DT (serial 7s) using the Tekscan Strideway (30Hz, Boston, MA). The raw CoP trajectory for the best tandem gait trial of each condition (fastest overall) was exported and further analyzed using a custom MATLAB code. All turns during the tandem gait trials were removed and each straight path walking was composed together. The raw CoP data in the AP and ML directions were smoothed using empirical mode decomposition and then excursion and velocity data were calculated. T-tests compared the time to complete ST and DT while two multivariate ANOVAs compared CoP in the AP and ML directions. **RESULTS:** SRC took significantly longer to complete the ST trial ($p=0.006$; SRC=14.2±4.4s, CON=10.8±2.1s) but not the DT trial ($p=0.279$). The SRC group had a larger VOMS near-point convergence (NPC) ($p=0.007$; SRC=9.5±5.5cm, CON=5.2±2.9cm) and a higher VOMS change score ($p<0.001$; SRC=19.7±6.4, CON=0±0). A significant omnibus effect was noted in AP direction ($p=0.015$) but not in the ML direction ($p=0.996$) for the tandem gait CoP data. Follow-up comparisons noted that in the AP direction during ST, SRC had slower CoP excursion ($p=0.003$; SRC=1.6±0.2cm, CON=1.9±0.4cm) and lower CoP velocity ($p=0.004$; SRC=54.2±7.7cm/s, CON=66.1±14.2cm/s) but no differences during DT. **CONCLUSIONS:** These results suggest that during instrumented ST tandem gait, SRC have a more conservative and slower heel-to-toe stepping pattern.

The Head Shake Sensory Organization Test And Screening Individuals With Self-reported History Of Concussion

Adrian Aron, Daniel Miner, Brent Harper, Ashley Dudding, Ashley Humphries, Sam Lawrence, Brooke McDermott, Radford University, Roanoke, VA. (Sponsor: A. Lynn Millar, FACSM)
(No relevant relationships reported)

PURPOSE: The Sensory Organization Test (SOT) assesses impairments in postural control following acute concussion. Head Shake Sensory Organization Test (HS-SOT) is a superior test that challenges the vestibular system to help detect more subtle deficits missed by SOT. The purpose of this study was to assess the accuracy of the HS-SOT in identifying residual impairments of postural control in individuals with self-reported history of concussion.

METHODS: The Ohio State University-Traumatic Brain Injury Identification Method (OSU TBI-ID) determined self-reported history of concussion while NeuroCom was used to perform HS-SOT. Twenty-nine subjects were included (11 males and 18 females, mean age 25.2 ± 3.7; history of concussion: $n=14$, 5 males and 9 females, mean age 25.7±3.5; no concussion: $n=15$, 6 males and 9 females, mean age 24.8±4.0). Independent T-Tests were completed to determine performance differences based on history of concussion.

RESULTS: HS-SOT fixed surface equilibrium ratio was similar ($p = 0.988$) between those without a history of concussion (0.998 ± 0.024) and those with a history of concussion (0.998 ± 0.026). Furthermore, HS-SOT sway reference surface equilibrium ratio was also similar ($p = 0.431$) between those without a history of concussion (0.871 ± 0.128) and those with a history of concussion (0.9136 ± 0.160). Within subjects with a history of concussion, younger subjects (23.4 ± 0.8) had a lower sway index compared to older (30.3 ± 3.6) individuals (0.85 ± 0.11 vs 1.09 ± 0.16, $p=0.021$). In addition, the younger group trended toward a more recent history of a concussive event (4.7 ± 4.8 vs. 8.0 ± 3.4, $p=0.25$).

CONCLUSIONS: There was no difference in HS-SOT in subjects with or without a history of concussion demonstrating an inability to detect performance impairments. Of those with a concussion, the HS-SOT significantly identified subtle performance deficiencies in younger individuals, suggesting that time from concussion tends to normalize sub-clinical deficits. This indicates that postural control impairments initially persist but resolve over time, which may place individuals at risk for injury during this window of recovery.

Comparing Functional Movement Under Single And Dual Task Conditions: Implications For Post-concussion Management

Landon B. Lempke, Rachel S. Johnson, Jeonghoon Oh, Julianne D. Schmidt, Robert C. Lynall. University of Georgia, Athens, GA.
Email: lblempke@uga.edu
(No relevant relationships reported)

Movement assessments are commonly performed while strictly completing the assessment (single task). Sport movement is highly dynamic and requires concurrent

cognitive processing and movement (dual task). Simultaneous cognitive processing and movement may alter human movement, but to date has not been examined. **PURPOSE:** To compare kinematic and kinetic outcomes between single and dual task functional movement among healthy individuals. **METHODS:** Physically active participants (n=41, 49% female; 22.5 ± 2.1yrs; 172.5 ± 11.9cm; 71.0 ± 13.7kg) completed a functional movement assessment (cut) under single and dual task (subtracting by 6's or 7's) conditions in random order. The cut involved jumping forward from a 30cm tall box set at 50% of the participant's height and performing a single, dominant-leg, 45 degree cutting motion after landing (four trials). The cut was completed in an eight camera (Qualisys; 120Hz) 3D motion capture space with two piezoelectric force plates (Bertec; 1200Hz). Multiple repeated measures ANOVAs ($\alpha=0.05$) compared hip, knee, and ankle joint angles (deg) and normalized joint moments (Nm/kg) at initial contact in sagittal and frontal planes, and normalized peak vertical ground reaction force (vGRF; N/kg) between single and dual task conditions. **RESULTS:** Results are presented in the Table. Dual task resulted in significantly greater ($p=0.03$) varus knee moments compared to single task. Dual task vGRF force was significantly less ($p=0.01$) compared to single task. No other outcomes were significant ($p\geq 0.06$). **CONCLUSION:** Slight kinematic and kinetic differences were observed between single and dual task during the cut. Reduced vGRF and greater varus knee joint moments during dual task may indicate altered movement during concurrent cognitive loading. Our findings provide initial metrics for future post-concussion biomechanical comparisons. Supported by the University of Georgia College of Education Early Career Faculty Research Grant.

Table. Dominant Leg Kinematic and Kinetic Outcomes During a 45-Degree cut at Initial Ground Contact.

Outcome	Value Direction	Single Task	Dual Task	P-Value
		Mean (95% CI)	Mean (95% CI)	
Hip Angle (deg)	Flexion	27.4(23.4 – 31.4)	25.9(22.0 – 29.9)	0.50
	Adduction	13.1(11.2 – 15.0)	12.6(10.7 – 14.5)	0.40
Knee Angle (deg)	Flexion	4.9(2.1 – 7.8)	4.9(2.0 – 7.7)	0.93
	Varus	1.9(0.8 – 3.1)	1.9(0.7 – 3.0)	0.65
Ankle Angle (deg)	Plantarflexion	43.2(38.9 – 47.6)	40.3(36.0 – 44.7)	0.06
	Inversion	12.3(10.4 – 14.3)	12.0(10.0 – 13.9)	0.45
Hip Moment (Nm/kg)	Extension	1.07(0.95 – 1.19)	0.99(0.87 – 1.11)	0.15
	Abduction	-0.18(-0.23 – -0.12)	-0.18(-0.24 – -0.13)	0.74
Knee Moment (Nm/kg)	Extension	-0.63(-0.68 – -0.58)	-0.63(-0.68 – -0.58)	0.96
	(+): Varus(-): Valgus	-0.0015(-0.05 – -0.02)	0.0025(-0.03 – 0.04)	0.03 ^a
Ankle Moment (Nm/kg)	Dorsiflexion	0.09(0.07 – 0.12)	0.09(0.07 – 0.11)	0.78
	Eversion	0.03(0.02 – 0.03)	0.02(0.02 – 0.03)	0.22
Peak Vertical Ground Reaction Force (N/kg)		2.90(2.79 – 3.01)	2.82(2.71 – 2.93)	0.01 ^a

^a Significant at $p \leq 0.05$.

Dual-task Balance Control in Adolescent Athletes Following Concussion
 Tracy Zaslow, Camille Burton, Nicole Mueske, Adriana Conrad-Forrest, Bianca Edison, Tishya Wren. *Children's Hospital Los Angeles, Los Angeles, CA.* (Sponsor: Tracy Zaslow, FACSM)
(No relevant relationships reported)

Purpose: Previous research has identified deficient dual-task balance control at the time of return to play (RTP) and possible worsening after RTP in older adolescents/young adults with concussion. We investigated these issues in younger concussion patients, hypothesizing they would have slower walking speed and increased medial-lateral (ML) center of mass (COM) movement, which would normalize by RTP but worsen after resuming activity.

Methods: 13 concussed adolescents (7 male; age 10-17 years) were prospectively evaluated at their initial visit (mean 18, range 4-43 days post-concussion), at RTP clearance (46, range 12-173 days post-concussion), and one month later (26, range 20-41 days post-RTP). Standing balance was assessed using range and root mean squared (RMS) COM motion during 2-leg, eyes open standing while performing audio Stroop, side-to-side head turn (HT), and side-to-side thumb tracking tasks. Dynamic balance was assessed using walking speed and COM ML range and velocity during walking alone and with head turn and verbal fluency (reciting words starting with "F") dual tasks. Patients were compared to 11 controls (3 male) using t-tests, and changes over time were evaluated using linear mixed-effects regression. **Results:** During standing, patients had higher COM ML RMS than controls at baseline during HT and higher COM anterior-posterior (AP) range during thumb tracking. COM ML motion decreased from baseline to RTP (HT range -6.5mm, $p=0.058$; HT RMS -16.8mm, $p=0.002$; thumb range 9.2mm, $p=0.012$) and increased from RTP to 1 month follow-up (HT RMS +10.0mm, $p=0.040$; Stroop RMS +8.4mm, $p=0.086$). Patients walked slower than controls at baseline during all tasks, and COM ML range was higher in patients during verbal fluency at baseline and RTP. Walking speed increased from baseline to RTP during verbal fluency (+7.8cm/s, $p=0.044$), from RTP to post-RTP in single task walking (+6.1cm/s, $p=0.041$), and at each successive visit during HT (+6.0cm/s and +6.5cm/s, $p<0.07$). COM ML range decreased in patients from baseline to RTP with verbal fluency (-14.7mm, $p=0.011$) and from RTP to post-RTP in single task walking (-4.0mm, $p=0.061$). **Conclusion:** Balance control deficits improved by RTP and only worsened post-RTP during dual-task standing, suggesting that current conservative treatment protocols are appropriate.

D-44 Clinical Case Slide - Oncology II

Concerning The Utility Of Ultrasound Imaging In Soft Tissue Lesions
 Chad Curtis¹, Christopher Jordan². ¹*St. Joseph Medical Center, Osceola, IN.* ²*St. Joseph Medical Center, Mishawaka, IN.*
(No relevant relationships reported)

HISTORY: A 13-year-old female initially presented to her primary care physician with a complaint of right forearm swelling. Her symptoms were present for approximately two weeks and she experienced constant pain in the area. Her pain and swelling were located over the dorsal aspect of the forearm. The patient's symptoms were initially presumed to be muscle strain and initial treatment included ibuprofen and ice. Of note the patient is right hand dominant. She had a follow up appointment two weeks later, and her symptoms were unchanged. Due to persistent symptoms x-rays were obtained, which were unremarkable. She was subsequently sent to the sports medicine office for possible ultrasound examination. Upon initial encounter with sports medicine clinic, the patient reported persistent pain and started to have intermittent numbness sensation in her 3rd - 5th digits. **PHYSICAL EXAMINATION:** Musculoskeletal exam of right upper extremity was completed. Inspection was without deformity or bruising. Palpation was with normal anatomy at elbow. No tenderness to palpation of the elbow was elicited. A firm mass over the right forearm extensor muscle bodies was identified in the region of the mid to proximal radius. There was also tenderness over this point. Her range of motion was within normal limits and was without pain. Her exam was significant for sensation deficit to soft touch at 3rd-5th digits. **DIFFERENTIAL DIAGNOSES:** 1. Hemangioma 2. Hematoma 3. Cystic structure 4. Malignancy **TEST AND RESULTS:** X-Rays Elbow - Normal x-rays of right elbow. Ultrasound - Hyperemic soft tissue muscle mass MRI - 2x1x4 cm gadolinium enhanced mass of anterolateral side of the mid-radius without obvious origin. Image-guided core needle biopsy Differential of PNET and monophasic synovial sarcoma. **FINAL DIAGNOSES:** Ewing Sarcoma **TREATMENT and OUTCOMES:** 1. Chemotherapy 2. Proximal radial diaphyseal resection and fusion of the distal radius with the proximal ulna. 3. NM PET was without FDG uptake to suggest recurrent or metastatic disease. 4. Follow up work up was significant for imaging with expected surgical changes and with apparent remission and without metastasis.

"Painless Fracture Hides Rare Bony Malignancy"Alexander Chasin¹, Amie Kim². ¹Brookdale University Hospital and Medical Center, Brooklyn, NY. ²Mount Sinai, New York, NY. Email: azc5154@gmail.com

(No relevant relationships reported)

HISTORY: 48 year old male with history of unprovoked DVT presents to the ED with left knee pain for 3 months. Symptoms began at rest, and described as sharp constant pain localized to the knee. Three weeks prior, he was evaluated by his primary care doctor and was clinically diagnosed with a knee sprain with conservative management. Two weeks ago, he felt an atraumatic "pop" in his lower extremity. Since that time he has since been unable to weight bear. No constitutional or B-type symptoms.

PHYSICAL EXAM: Thin, well appearing male, seated in a wheelchair. Seated exam was performed secondary to the patient's pain. He was unable to bear weight on his left lower extremity and it was held in passive internal rotation. His left hip had no tenderness over the greater tuberosity and he had limited range of motion. His left knee was without erythema, effusion or warmth and there was no tenderness over the medial or lateral joint lines. Range of motion of his knee was limited. No specialized tests were able to be performed given patients positioning and discomfort. His left ankle was nontender with no gross deformities. His dorsalis pedis pulse was 2+ and flexion/extension of the toes were intact.

DIFFERENTIAL DIAGNOSIS:

- 1) Hip dislocation/fracture, pelvic fracture / fragility fracture
- 2) Internal derangement of the knee
- 3) Femoral DVT
- 4) Pathological fracture

TEST AND RESULTS:

X-ray of Left Knee AP and Lateral

Displaced and angulated fracture of distal left femoral diaphysis.

MRI Left Lower Extremity (T1)

Abnormal soft tissue invades the mid to distal femoral shaft extending into anterior compartment of quadriceps and a portion of the short head of biceps femoris.

NM Bone Scan

Focal, mild to moderate increased tracer uptake noted in the left femur from the mid shaft to distal region.

Operative Biopsy Malignant fibrous histiocytoma / undifferentiated pleomorphic sarcoma

WORKING DIAGNOSIS: Occult femur fracture secondary to rare primary bone neoplasm**TREATMENT AND OUTCOMES:**

- 1) Patient transferred to outside facility for orthopaedic oncology service and operative plate fixation
- 2) Radiotherapy - post-operative of primary lesion site
- 3) Transfer to inpatient rehab facility with post-operative protocol
- 4) Remaining work-up and management follow-up pending - including oncologic imaging and therapy, surgical outcomes, rehabilitation course.

2028 May 28 4:25 PM - 4:45 PM

Finger Pain In A Professional Dog GroomerKevin Matthew Mullins, Eugene Yousik Roh. *Stanford University, Redwood City, CA.*

(No relevant relationships reported)

HISTORY: A 36-year-old right-handed female professional dog groomer with past medical history of PCOS, presents with a chief complaint of left hand digit 3 and 4 fingertip pain. She reports progressive discomfort for the past 10 months, worsened with tactile touch especially during work, and mildly improves with rest. Describes the pain as sharp electrical sensations rated 10/10 on pain scale, sensitive to cold weather. Outside facility workup included normal hand x-rays, cervical x-rays and a hand MRI. Electrodiagnostic/nerve conduction studies demonstrated mild carpal tunnel syndrome on the left without radiculopathy, for which she has tried a neutral wrist splint without improvement. She has been seen by her PCP, rheumatology, neurology, endocrinology, and orthopedic surgery, all without a confirmatory diagnosis. Her pain is now debilitating and thus she presents to Stanford for a 6th opinion.

EXAM: On inspection no swelling or discoloration. Severe tenderness with light touch of digit 3 at the eponychial fold, ulnar side. Limited active and passive digit 3 DIP flexion due to pain. Sensation decreased in dorsal digital median nerve branch digits 3 and 4. Remaining strength and sensation in the hand intact. Phalen's test at the wrist positive while tinel's was negative. Spurling's negative.

DIFFERENTIAL: 1. Median or Palmar Digital Branch Mononeuropathy. 2. C7 Radiculopathy 3. Digital Collateral Ligament Injury 4. Tumor 5. Complex Regional Pain Syndrome 6. Mallet Finger 7. Raynaud's Phenomenon

RESULTS: Point-of-care ultrasound significant for digit 3 solitary hypochoic lesion with clear boundaries and regular shape, and internal abundant hyperemia. Finger MRI showed 4 x 3 x 3 mm circumscribed T1 hypointense T2 hyperintense, enhancing lesion at dorsal aspect of the third distal phalanx.

DIAGNOSIS: Glomus Tumor

OUTCOME: Initiation of gabapentin, lidocaine cream for symptomatic relief and referral to orthopedics for definitive treatment with plans for left middle finger glomus tumor excision. The patient is currently pending surgery at the time of this submission, additional follow-up to be presented.

2029 May 28 4:45 PM - 5:05 PM

Posterior Shoulder Pain - Baseball PitcherMary Lynch, Jacob Sellon, Marc Gruner. *Mayo Clinic, Rochester, MN.*

Email: breen.mary@mayo.edu

(No relevant relationships reported)

HISTORY: Patient is a 20 year old right handed college baseball pitcher with a past medical history of ulnar neuritis. He presented with a 4 month history of right-sided inferior periscapular pain after increasing his pitching speed and frequency. This pain initially occurred only with high velocity pitches but progressed to occur with all pitching and some overhead reaching activities. It was associated with a catching sensation but otherwise no mechanical shoulder symptoms or neurologic arm symptoms. He denied constitutional symptoms.

PHYSICAL EXAM:**General:** Healthy appearing, athletic build.**Inspection:** No obvious asymmetry.

Palpation: Non-mobile, minimally prominent mass approximately golf ball size in diameter, just inferior and medial to the inferior angle of the scapula. This was mildly tender without fluctuance.

Musculoskeletal: Normal right shoulder ROM. No scapular dyskinesia.**Neurologic:** Normal right arm strength, sensation, and reflexes.**Special Tests:** Negative shoulder impingement signs.**DIFFERENTIAL DIAGNOSIS:**

Elastofibroma dorsi

Scapulothoracic bursitis

Snapping scapula

Lipoma

Sarcoma or other tumor

TESTS AND RESULTS:**X-rays:** Unremarkable.

Ultrasound: Well-circumscribed solid soft tissue mass overlying the posterior 7th/8th ribs.

MRI: 5.4 x 1 x 3.5 cm mass in the infrascapular region underlying the serratus anterior and latissimus dorsi. No rib erosion or extension into the intercostal musculature.

FINAL DIAGNOSIS: Images favored a benign process. After waiting to complete the current season, the mass was excised. The mass was deep to the serratus anterior muscle and adhered to the 7th rib. Pathology demonstrated fibroblastic proliferation, likely reactive due to repetitive microtrauma.

TREATMENT AND OUTCOME: No follow up imaging or additionally treatments were necessary. Six weeks after excision, patient was able to throw a baseball with no pain and return to off-season baseball training.

2030 May 28 5:05 PM - 5:25 PM

Acute Hip Pain In An Immunocompromised Soccer PlayerKathryn Stockbower. *The Children's Hospital of Colorado, Aurora, CO.* (Sponsor: Morteza Khodae, FACS)

Email: kathryn.stockbower@cuaenschutz.edu

(No relevant relationships reported)

HISTORY: A 15 year-old female with a history of Crohn's disease, celiac disease and primary sclerosing cholangitis on immune-modulating therapy (ustekinumab) presents with acute left hip pain. She had mild groin pain five days prior to presentation, with an acute worsening after soccer practice two days ago. There was no acute injury. She has been limping and reports fever to 38.3°C yesterday. Her PCP referred her to sports medicine clinic, and ordered Xrays and labs.

PHYSICAL EXAM: The patient is afebrile and appears well, but sits with her left hemi-pelvis elevated. There is no warmth or erythema of the skin overlying the left hip. There is tenderness to palpation over the anterior groin, anterior inferior iliac spine and anterior superior iliac spine. Range of motion of the left hip is limited and painful in all directions. Log roll, FADIR and FABER tests are all positive for anterior groin pain.

DIFFERENTIAL DIAGNOSIS: 1) Septic hip arthritis 2) Extra-articular myositis or abscess of hip flexors 3) Synovial chondromatosis 4) Tenosynovial giant cell tumor 5) Intra-articular chondroma 6) Sarcoma

TEST AND RESULTS:

MRI enterography small bowel (staging for inflammatory bowel disease, one year ago): incidentally noted synovitis of the left hip joint

Xray hip/pelvis, one year ago: subtle flattening of the left femoral head, possible erosion within the inferior femoral neck, slightly increased left hip joint space

XRay hip/pelvis, two days ago: left hip joint space widening and possible synovial calcification of the inferior hip joint capsule, progressive flattening and widening of the femoral head

Labs: CBC normal, ESR and CRP elevated from baseline

MRI hip with and without contrast: left hip joint effusion with multinodular/lobular intra-articular mass, mild erosions along the inferior femoral neck with reactive/inflammatory changes within the adjacent musculature

Percutaneous biopsy: Inflammatory synovial fluid without tumor cells or crystals.

Tissue pathology showed giant cell tumor

FINAL DIAGNOSIS: Tenosynovial Giant Cell Tumor (TGCT), formerly known as Pigmented Villonodular Synovitis (PVNS)

TREATMENT AND OUTCOMES: Arthroscopic debridement. The patient is doing well in physical therapy.

2031 May 28 5:25 PM - 5:45 PM

A Tibial Mass In A Zipline Instructor

Jennifer Oberstar. *University of Minnesota, Minneapolis, MN.*
(Sponsor: Suzanne Hecht, FACSM)

(No relevant relationships reported)

HISTORY: A 26 yo college female active as a summer Zipline instructor presented with a right mid-shaft tibial mass present for four months. The patient had regular periods, no weight loss, no food avoidance, no hx of stress fractures, but reported fatigue. She denied past injury involving her tibia and the tibia was completely asymptomatic with running. After returning to college and less activity 3 weeks ago, the mid-tibia became swollen and painful. Over the past month her symptoms were worse at night and somewhat relieved by ibuprofen. She presented to her student health clinic and x-rays reported focal cortical thickening at the anterior aspect of the midshaft tibial diaphysis. An initial MRI Radiology read reported no bony edema suggesting an old stress fracture. The patient was treated with a CAM boot for a possible stress reaction. The patient presented to the Sports walk-in clinic for a second opinion after experiencing even more tibial pain when wearing a CAM boot.
PHYSICAL EXAMINATION: Examination revealed Ht 5'7", Wt 160 lbs, BMI 25 kg/m², Pain 5/10. **CONSTITUTIONAL**: Healthy, no fever, alert & oriented. **SKIN**: 2 cm hard palpable mass on the subcutaneous border of the right mid-tibia. No erythema or edema. **MSK**: full ROM of her lower extremity, knee and ankle. Pain in tibia with squatting.

DIFFERENTIAL DIAGNOSIS:

1. Anterior tibial bone stress injury, chronic vs new
2. Reactive sclerosis surrounding an osteolytic lesion
3. Bone tumor, Osteoid osteoma

TEST AND RESULTS:

Radiographs of Tibia and Fibula:

1. Focal cortical thickening at the anterior cortex of the midshaft tibial diaphysis.

MRI Tibia and Fibula W & WO Contrast:

1. Cortical thickening within the middle third of the anterior tibial shaft.
2. No bony edema, periostitis, or other acute pathology to suggest acute stress reaction or acute osteoid osteoma.
3. Images reviewed with MSK Radiologist and Orthopedic Oncologist. Cross-sectional CT was recommended.

CT Tibia and Fibula Lower Leg WO Contrast:

1. Thickened area of the anterior cortex of the tibia which shows a circular nidus with a central calcified area.

FINAL WORKING DIAGNOSIS:

1. Osteoid Osteoma

TREATMENT AND OUTCOMES:

1. NSAIDs trialed with minimal relief
2. Discontinue CAM boot
3. Referral to Orthopedic Oncologist
4. Scheduled for radiofrequency ablation
5. Avoid weight lifting/impact activities for 2 months

Chest Wall Pain In A Marathon Runner

Joseph G. Dadabo, Monica Rho. *Shirley Ryan AbilityLab/ Northwestern University, Chicago, IL.* (Sponsor: Joseph Ihm, FACSM)

Email: jdadabo@sralab.org

(No relevant relationships reported)

History: A 39-year old male marathon runner presented with 1 year of left-sided anterolateral chest wall pain at ribs 10 and 11. Pain started insidiously, without trauma or other inciting incident. Pain primarily occurred with running, and typically worsened as his pace increased. Lifting weights, deep breathing, and prolonged sitting did not exacerbate pain. He denied cough, dyspnea, or wheezing.

Physical Examination: Normal chest wall expansion. No visual deformity along the ribs or costal cartilage. Tenderness to palpation was noted along the left 10th and 11th ribs and intercostal muscle anterior to the mid-axillary line. No tenderness at adjacent segments or at the same segment on the contralateral chest wall. Mild left-sided chest wall pain with leftward thoracic rotation.

Differential Diagnosis:

1. Costochondritis
2. Tietze syndrome
3. Slipping rib syndrome
4. Thoracic radiculitis
5. Pleurisy

Tests and Results:

MRI Chest Wall: Focal thickening and edema along left lower ribs at region of pain, with surrounding soft tissue swelling. No pleural or pericardial effusion. No bone marrow edema within visualized osseous structures.

Ultrasound Chest Wall: Significant signal impedance and focal thickening noted along the intercostal muscle of the left 10th and 11th ribs at the area of maximal tenderness along the anterolateral chest wall. No comparable signal changes are observed at adjacent segment levels or the same segment on the contralateral chest wall.

Final/Working Diagnosis:

1. Tietze syndrome

Treatment and Outcomes:

1. Performed corticosteroid/lidocaine injection to left 10th-11th rib intercostal muscle under ultrasound guidance
2. Pain diary for 6 hours immediately following injection
3. Routine marathon training as tolerated
4. Ice as needed after running
5. Pain resolved following injection. Inflammation and intercostal muscle hypertrophy resolved on repeat ultrasound 2 months later.
6. Patient completed Berlin and Chicago Marathons in 2019

2037 May 28 4:05 PM - 4:25 PM

An Unusual Cause Of Lower Leg Pain - Long Distance Running

Wayne Elton Derman, FACSM¹, Melissa Van Vuuren¹, James Tunnickliffe². ¹Stellenbosch University, Cape Town, South Africa. ²Matley and Partners, Cape Town, South Africa.
Email: ewderman@iafrica.com

(No relevant relationships reported)

HISTORY: A 42 yr runner presented to the sports medicine clinic two weeks after having successfully completed an ultra-marathon complaining of left calf pain. The onset of the pain occurred the day after the race but within a short period the pain was present after walking short distances. The pain was claudicant, with accompanying foot paraesthesia and leg weakness. Rest pain was absent. Besides hypercholesterolaemia and previous kidney stones, the patient was well, a non-smoker with some symptoms of atopy but no other relevant medical or family history.

PHYSICAL EXAMINATION: The patient appeared to be generally well, with normal vital signs. On inspection of his limbs, there was no obvious swelling, discoloration or evidence of tissue loss. On palpation the left limb was slightly cooler to touch with a prolonged capillary refill time. On examination of his pulses, his upper limb pulses were symmetrical and equal but on examination of his lower limbs his left femoral pulse was slightly diminished, with a soft bruit. The left popliteal and dorsalis pedis pulses were absent. He was unable to run, and was only able to walk approximately 100 m. No left foot pulses felt post exercise or heard on office Doppler examination.

DIFFERENTIAL DIAGNOSIS:

1. Musculoskeletal injury eg gastroc tear
2. Vascular occlusion: popliteal artery entrapment, atherosclerotic occlusion, other occlusive disease
3. Posterior chronic compartment syndrome
4. Referred pain

TEST AND RESULTS:

1. Duplex Doppler was performed but was obscured by bowel gas, yet aorta and proximal common iliac was patent. The distal common iliac and proximal external iliac could not be visualized. Distal external iliac and common femoral vessels were patent.
2. Angiogram performed of the external iliac artery, demonstrated a string-like appearance pathognomonic of fibromuscular dysplasia. A full visceral angiogram was normal.

FINAL WORKING DIAGNOSIS: Fibromuscular dysplasia of the external iliac artery

TREATMENT AND OUTCOMES:

1. A transverse arteriotomy was initially made in the CFA which revealed a 50% stenosis caused by a medial soft plaque. Fogarty thrombectomy was performed on the SFA resulting in good backflow
2. A long saphenous venous patch used.
3. Anticoagulation
4. Initial rest with gentle mobilization
5. Return to sport programme

Hip And Thigh Pain In A Runner

Matthew LaCourse, Brian Liem. *University of Washington, Seattle, WA.*

Email: mattlac@uw.edu

(No relevant relationships reported)

HISTORY: A 46-year-old male runner with a history of right-sided L3 radiculopathy presented with one month of recurrent right hip and thigh pain. He denied any trauma, inciting event, or recent alteration in his running regimen. Pain was described as stabbing, and localized to his right lateral hip with radiation down his anterior thigh to his knee. He also reported numbness and tingling down his anterior thigh to the knee. Recently, he experienced an incident of sudden bowel urgency with near bowel incontinence. No bladder incontinence or perineal numbness. He has a history of chronic gastroesophageal reflux disease and has taken omeprazole daily for 10 years.

PHYSICAL EXAMINATION: Full and symmetric lower extremity strength except for 4/5 with right hip abduction. Sensation intact to light touch at his hips, thighs, groin, buttocks, and scrotal region. No tenderness at the lumbar paraspinals, buttock musculature, greater trochanters, or anterior hip. Negative straight leg raise and reverse straight leg raise. Full, non-painful range of motion with lumbar flexion and extension. No pain with resisted hip flexion, or passive end range hip flexion. Negative FABER, FADIR, femoral nerve stretch.

DIFFERENTIAL DIAGNOSIS: 1. Recurrent Upper Lumbar Radiculopathy 2. Hip Flexor Tendinopathy 3. Iliotibial Band Syndrome 4. Hip Osteoarthritis 5. Femoral Stress Fracture

TEST AND RESULTS: 1. Right Hip X-Ray:- Mild osteoarthritis of bilateral hips.- Wedge sclerosis and mild periostitis of the medial aspect of the right femoral neck. 2. Lumbar Spine X-Ray:- Mild intervertebral disc height loss at T12-L1, L2-L3, and L5-S1.

3. Right Hip MRI:- Linear T1 focus with surrounding STIR hyperintensity along the medial aspect of the right femoral neck, compatible with a stress fracture.
 4. Lumbar Spine MRI:- Right foraminal/extraforaminal disc protrusion at L3-L4.
 5. DEXA Scan:- No signs of significant osteopenia or osteoporosis at the spine or hips.
 6. Calcium, 25-OH Vitamin D, Parathyroid Hormone levels: Normal
- FINAL WORKING DIAGNOSIS:** Right femoral neck stress fracture, potentially due to chronic proton pump inhibitor use
- TREATMENT AND OUTCOMES:**
1. Referral to orthopedic surgery 2. Toe-touch weight bearing for 6 weeks. 3. Discontinuation of omeprazole. 4. Consideration of future referral to endocrinology.

2039 May 28 4:45 PM - 5:05 PM

Cardiovascular-Running

Kevin Kuo¹, Amie Kim², Thomas Nguyen². ¹Icahn School of Medicine at Mount Sinai, St. Luke's-West, New York, NY. ²Icahn School of Medicine at Mount Sinai, Beth Israel, New York, NY.

(No relevant relationships reported)

History: A healthy, 26-year-old marathon runner was brought to the emergency department (ED) for altered mental status during an eighteen-mile run. At his fifteenth mile, he reported feeling increasingly warm with burning sensations. He sustained a witnessed collapse with loss of consciousness. He was alert in the ED, asymptomatic, but with anterograde amnesia. He denied prodrome including headache, dizziness, weakness, chest pain, dyspnea, or palpitations. During his ED course, he sustained a second witnessed episode of vomiting and syncope.

Physical Examination: Comfortable appearing male. Skin was warm to touch, mildly flushed. Lungs were clear to auscultation. Cardiac exam regular rate and rhythm with normal S1 and S2. He exhibited mild tenderness to palpation in lower distal extremities without peripheral edema. Compartments were soft. He was neurologically intact.

Differential Diagnosis:

- Heat syncope
- Metabolic disorder
- Cardiogenic - Acute coronary syndrome, cardiomyopathy, exercise related dysrhythmia, channelopathy
- Seizure
- Rhabdomyolysis

Test and Results:

- CPK 7,639, peaked at 15,551
- Troponin 0.553, peaked at 2.19
- EKG with t-wave inversions and ST depressions in precordial leads
- pH 7.27, pCO₂ 41.3, Lactate 5.9
- Na 143, K 5.2, Cl 107, Bicarb 18.9 Glucose 97 Calcium 10.6
- Bun 24 Cr 2.2
- Urine tox negative

Final Working Diagnosis: Rhabdomyolysis

Treatments and Outcomes:

- Admitted to the cardiac ICU for NSTEMI secondary to rhabdomyolysis, recurrent syncope, acute kidney injury, and metabolic acidosis.
- Cardiac echo showed normal ejection fraction without wall motion abnormalities.
- EKG abnormalities normalized on 5 days continuous telemetry
- Maintained on intravenous fluids and bicarbonate drip. Secondary organ function improved, with discharge on hospital day 5
- NSTEMI and recurrent syncope are unusual presentations of rhabdomyolysis in young, healthy athletes
- Pending - outpatient electrophysiology, genetic screening, cardiac rehabilitation, precautions in return to distance running

2040 May 28 5:05 PM - 5:25 PM

A Unique Overuse Stress Injury In A Professional Triathlete

Nancy Phu¹, Jonathan Minor². ¹Burrell College of Osteopathic Medicine, Las Cruces, NM. ²SPARRC - Sports Medicine, Rehabilitation and Concussion Care, Tucson, AZ.

(No relevant relationships reported)

HISTORY:

A 28-year-old male professional triathlete presented with acute on chronic low back pain for five days after completing an Olympic distance triathlon. He developed low back and hip pain the evening of the race. Pain was worsened by laying supine, sitting and walking. He reported back stiffness, which improved through the day. PT and dry needling offered little improvement. Nine months earlier he was seen for low back pain, diagnosed with sacroiliitis. This was managed by a licensed physical therapist with resolution. MRI performed years earlier identified disc bulge at L3-L4.

PHYSICAL EXAMINATION:

Inspection was unremarkable, without swelling, deformity, or ecchymosis. Mild tenderness over the piriformis and gluteus medius. No point tenderness over the PSIS, SI joints, or spinous processes. Range of motion of the trunk was full but painful with

extension, rotation to the right, and Kemp test to the right. No pain with trunk flexion, rotation to the left, side bending, or Kemp test to the left. Familiar right posterior hip pain with axial load of the flexed hip. Pain with resisted hip flexion on the right. Mild familiar right posterior hip pain with resisted hip flexion on the left. FABER, piriformis stretch, SI torque tests, and straight leg raises negative bilaterally.

DIFFERENTIAL DIAGNOSIS:

1. Strain of pelvic muscle
2. Sacroiliitis
3. Pelvic stress injury
4. Lumbo-sacral radiculopathy

TEST AND RESULTS:

MRI pelvis without contrast revealed bone marrow edema of the right inferior iliac bone adjacent to the SI joint with subtle incomplete fracture line, suggesting grade 4 stress fracture. Calcium, alkaline phosphatase, phosphorus, and magnesium levels within normal range. 25-OH-Vitamin D within normal range, perhaps lower end for high-level athlete (46.6 ng/mL). CBC and celiac screening within normal limits.

FINAL WORKING DIAGNOSIS:

Stress fracture right iliac bone

TREATMENT AND OUTCOMES:

1. 8-weeks rest from impact activities (running and cycling).
 2. Swimming with pull buoy for 4 weeks with gradual kicking introduction.
 3. Elliptical and aerobic cycling at 6 weeks, with guided power advancement.
 4. Calcium/vitamin D supplementation.
 5. Targeted PT strengthening.
- Outcome - pain free with progression and returned to uninhibited training at 12 weeks.

D-46 Clinical Case Slide - Shoulder II

Atypical Nontraumatic Shoulder Pain In A Baseball Player

Stacie Hirota¹, Emily Dixon², Richard Okragly¹. ¹*Trihealth Primary Care Sports Medicine, Cincinnati, OH.* ²*Trihealth Orthopedic and Sports Institute, Cincinnati, OH.* (Sponsor: Henry Stiene, FACSM)
(No relevant relationships reported)

HISTORY: 15 year old male high school baseball player with past medical history of asthma, who presented with right shoulder pain. Pain started after swinging in a baseball tournament, with no specific trauma. Pain was located posterior. He was able to continue playing baseball, however pain persisted. Initially he tried heat, ice and ibuprofen with no improvement. Pain progressively worsened over the week with walking, deep breathing and coughing. Additional symptoms included radiation into his neck and shallow breathing. He pursued evaluation at the Emergency Department. His vitals were stable with mild tachypnea, saturating 100% on room air and pulse of 72. Right first rib fracture was noted on CXR. He was discharged with ibuprofen and referral to Sports Medicine. **PHYSICAL EXAMINATION:** Vital signs stable. Respiratory exam clear to auscultation with good air movement throughout and no distress. Cervical exam with full range of motion and strength in flexion, extension, side bending and rotation with mild pain with resistant right-side bending. Right shoulder exam showed no obvious deformities, swelling or bruising. Tenderness over right supra and infraclavicular areas. Hypertonic scalene and trapezius muscles on the right. Range of motion demonstrated glenohumeral internal rotation deficiency with internal rotation of 20 degrees and external rotation of 110. **DIFFERENTIAL DIAGNOSIS:** Clavicle fracture. Pneumothorax. Scalene muscle strain. Scapula

fracture. SC or AC separation. **TEST AND RESULTS:** CXR 2 views demonstrated a transverse fracture of the first rib on the right with minimal displacement **DIAGNOSIS:** Right first rib fracture **TREATMENT AND OUTCOMES:** 1. Repeat imaging at 3 weeks post injury showed minimal callous formation. 2. Advised strict rest with non-weight bearing of the right upper extremity until repeat imaging. 3. Physical therapy for glenohumeral internal rotation deficiency found on evaluation. Including aggressive stretching and strengthening exercises for 4-6 weeks. 4. Re-evaluation at 7 weeks post injury showed no tenderness with palpation. 5. Repeat imaging at 7 weeks post injury finally showed callous formation. 6. Return to play with no restrictions at 7 weeks post injury after repeat x-rays showed callus formation, no tenderness with palpation, and full strength and range of motion.

2045 May 28 4:05 PM - 4:25 PM
Chest Wall Injury-CrossFit

Christian Douthit, MD, Hunter Miers, Mimi Zumwalt, MD.
Texas Tech University Health Science Center, Lubbock, TX.
 (Sponsor: Jacalyn McComb, FACSM)
(No relevant relationships reported)

HISTORY: 21 y/o M RHD CrossFit Coach sustained an injury to his R upper extremity while performing the “muscle up” exercise on a high bar about six weeks prior to presentation. He felt a painful pop in his shoulder/arm area after which he experienced bruising near his axilla/chest wall then unable to complete his workout. He continued to have pain/weakness along with difficulty working out with his usual gym routine, especially exercises involving pushing maneuvers. He was initially seen by another Orthopaedist, an MRI obtained, then referred to our Sports clinic. Other than a history of rapid weight loss of over 100 pounds a couple of years prior to the traumatic episode, he denies any supplement usage.

PHYSICAL EXAMINATION: Ventral Trunk/R upper extremity: loss of R chest wall contour in the “hands on hips” position/asymmetric axillary fold; TTP at bicipital groove; shoulder-painful ROM arc upon extreme abduction/elevation; weakness/pain with resisted IR/horizontal adduction.

- DIFFERENTIAL DIAGNOSIS:** 1. R LH biceps tendon rupture
 2. R pectoralis muscle tear
 3. R pectoralis tendon rupture

TEST AND RESULTS: R shoulder XR plain films without abnormality MRI show signal changes in pectoralis major tendon consistent with rupture of humeral detachment/retraction into chest wall; posterior glenoid labral tear

FINAL WORKING DIAGNOSIS: R pectoralis major tendon rupture

TREATMENT AND OUTCOMES: 1. Patient underwent subacute repair with Achilles allograft augmentation 2 months post-injury.

2. He was placed in a shoulder immobilizer for 6 weeks and formal PT started at 2 weeks.
3. At his last visit 5 months post-op he was doing very well, progressing with self PT rehab exercises in the gym, no pain with daily activities and pleased with cosmesis/symmetrical chest muscle contour. He started working out again and back to approximately 80% muscle strength/endurance with push-ups/pull-ups but avoiding explosive movements that would put him at risk of reinjury.

2046 May 28 4:25 PM - 4:45 PM

Shoulder Injury - Soccer, Water Polo

(No relevant relationships reported)

HX: 3 Division I athletes at 1 university.

Case 1- 21F soccer center midfielder presented with 1 month of insidious L shoulder pain that started posteriorly at the rhomboids and slowly migrated anteriorly. She denied any trauma. All activity worsened the pain, particularly shoulder ROM. She completed 6 weeks of rest and PT without improvement.

Case 2- 19M water polo player presented with 2 months of R posterior shoulder pain without preceding trauma. He improved with 2 weeks of light activity and PT, but the pain worsened as he increased activity and acutely worsened after contact play.

Case 3- 19M water polo player presented with 2 weeks of insidious onset L posterior shoulder pain. While executing power cleans, the pain became severe and he went to the ED.

EXAM:

Case 1-Diffuse pain limited L shoulder ROM. +mild GH internal rotation deficit. +tenderness and spasm of L trapezius, neck, levator, posterior deltoid, rhomboids. Spurling's (-). RTC testing nl except for pain with supraspinatus testing. O'Brien's (-). Case 2-NI visual inspection. The R shoulder had full ROM with mild discomfort posteriorly with full abduction. R rhomboid major tender to palpation. RTC testing nl; O'Brien's (-).

Case 3-NI inspection, ROM. L rhomboid major tender to palpation. RTC testing nl, biceps testing (-).

DDX:1. Rhomboid strain 2. Myofascial pain 3. Suprascapular nerve impingement 4.

Thoracic outlet syndrome

TESTS/RESULTS: Case 1-

L shoulder XR- nondisplaced stress fracture L 1st rib

Bedside U/S- cortical irregularity of 1st rib

CT chest w/o contrast- stress fracture L 1st rib

Case 2-

R shoulder XR,R ribs XR,MR RUE w/o contrast- nl

Bedside U/S- cortical irregularity of R 1st rib

Retrospective review of original XRs revealed subtle cortical irregularity of R 1st rib

CT chest w/o contrast- nondisplaced stress fracture R 1st rib

Case 3-

CXR,L shoulder XR,CT chest w/o contrast- nondisplaced fracture L 1st rib

Bedside U/S- L 1st rib fracture with large callus formation

FINAL DX:1st rib stress fracture

TX/OUTCOME:All cases with 1st rib stress fracture healed with standard relative rest, calcium and Vitamin D supplementation.

2047 May 28 4:45 PM - 5:05 PM

Back And Shoulder Pain - Heavy Lifting

Rijo Maracheril¹, Amie Kim², Kaushal Shah³. ¹Mount Sinai Hospital, New York, NY. ²Mount Sinai Hospital Beth Israel, New York, NY. ³Weill Cornell Medicine, New York, NY.
Email: rijo.maracheril@gmail.com
(No relevant relationships reported)

History

52 year-old male presents with right (R) upper back pain and R anterior chest pain. Presented to Emergency Department (ED) for R scapular pain after pulling a piano 1 week ago. Clinically appreciated painful R scapular stabilizers without swelling or bony tenderness. Discharged with analgesia and muscle relaxant. Subsequently developed erythema at site and went to second ED. Clinically evaluated and discharged with opiate. Erythema progressed, and patient returned to ED.

Physical Examination

Inspection with erythema extending into R lateral neck. Blanching and warm bilateral anterior chest wall. Tenderness on palpation greater on R than L including pectoralis origin, SC joint. No crepitus. Heart and lung sounds normal, painless chest excursion. R shoulder painful adduction with FROM. R scapula painful protraction and retraction. R AC joint painless scarf sign. Cervical spine, left shoulder, bilateral elbow without additional findings.

Differential diagnosis

1. Cellulitis/Necrotizing fasciitis
2. Thoracic outlet syndrome
3. Pectoralis myositis
4. Thrombophlebitis/DVT
5. Osteomyelitis/Septic joint

Tests and Results Remarkable Labs

- WBC 15.8
- CPK 68
- CRP 460

- ESR 108

- Alk Phos 253

Chest X-Ray

- Paratracheal lymphadenopathy

CT Chest with Contrast

- Fluid collection with inflammatory changes midline between pectoralis major

muscles without gas at the level of sternal notch and manubrium

- Asymmetric soft tissue thickening in the R clavicular head, SC joint, and retrosternal region with fluid collections

MRI Chest with/without Contrast

- Sternomanubrial effusion 2.3 cm posteriorly

- R 1st rib Osteomyelitis

- R supraclavicular clavicle fluid collection 4.6 x 1.5 x 2.6 cm

Final/Working Diagnosis

Septic Arthritis

Treatment and Outcomes

1. Source unable to be found: echocardiogram WNL, drug screen negative, HIV/Hepatitis B & C/EBV/Thyroid studies negative, esophagram WNL
2. Blood cultures positive for MSSA. IR aspiration of body fluid performed without speciation. PICC line placed with 8 weeks of IV cefazolin.
3. Hospital course complicated by non-occlusive thrombus in R subclavian/proximal SVC - started on apixiban for 6 months.
4. Serial CT with resolution of infection. One month inpatient, discharged to outpatient rehabilitation.
5. Pending outpatient ID and CT surgery, serial vascular imaging.

2048 May 28 5:05 PM - 5:25 PM

Posterior Shoulder Instability In A 17 Year Old Wrestler: A Case Report.

Kathryn Alfonso¹, Jason Lee². ¹Mayo Clinic, Rochester, MN. ²Mayo Clinic Health System, Faribault, MN.
Email: alfonso.kathryn@mayo.edu
(No relevant relationships reported)

HISTORY

A 17 year old male wrestler presented to the sports medicine clinic with superoposteriorly located right shoulder pain and apprehension with overhead movements 2 days after sustaining a posterior shoulder dislocation. He received an on-site closed reduction, and was seen following the match at a local emergency room with arm numbness. He was placed in a sling after unremarkable radiographs and symptom resolution.

PHYSICAL EXAMINATION

No erythema, ecchymosis, or edema about the right shoulder joint. Tender to palpation at AC joint, acromion, and anterior capsule. Active abduction 70°, flexion 80°. External rotation 20° (pain limited). Full strength with elbow, wrist, and finger flexion and extension. Empty can, Speed's and anterior apprehension were positive; Neer's, Hawkins's, O'Brien's, and Speed's and posterior apprehension were negative.

DIFFERENTIAL DIAGNOSIS

1. Bankart lesion
2. Hill-Sachs lesion
3. Labral tear
4. Rotator cuff tear
5. Humeral fracture

TEST AND RESULTS

Right shoulder and clavicle radiographs: unremarkable.

Right shoulder MR arthrogram:

- Tear at the humeral attachment of the posterior band inferior glenohumeral ligament.
- Partial thickness teres minor tear at inferior margin insertion.
- No reverse Hill-Sachs lesion.

FINAL WORKING DIAGNOSIS

Complete reverse humeral avulsion of the glenohumeral ligament lesion (rHAGL) and isolated teres minor avulsion.

TREATMENT AND OUTCOMES

1. A right shoulder arthroscopic rHAGL and teres minor repair was performed 3 weeks after the injury.
 2. The slow posterior Bankart protocol was initiated post-operatively for 6 weeks duration with progression to active range of motion and standard shoulder stabilization protocol therapy.
 3. Pain free with full strength and range of motion at 3 months post-op.
 4. Cleared to return to sport at 5 months post-op.
- rHAGL lesions with concurrent teres minor avulsions are a rare cause of posterior shoulder instability, and should be considered when a patient presents with posterior shoulder pain and instability following a posterior shoulder dislocation. In the absence of therapy or surgical repair, there is a risk of recurrent dislocations and the development of chronic degeneration. There are limited reported cases in the literature, with return to play reported 5-8 months post-operatively.

 Non-Exercise Estimated Cardiorespiratory Fitness And Mortality From All-Causes, Cardiovascular Disease And Cancer In The NIH-AARP Diet And Health Study**

Baruch Vainshelboim¹, Jonathan Myers, FACSM¹, Charles Matthews, FACSM². ¹*Veterans Affairs Palo Alto Health Care System/ Stanford University, Palo Alto, CA.* ²*National Cancer Institute, Bethesda, MD.* (Sponsor: Charles Matthews, FACSM)
 Email: baruch.v1981@gmail.com
 (No relevant relationships reported)

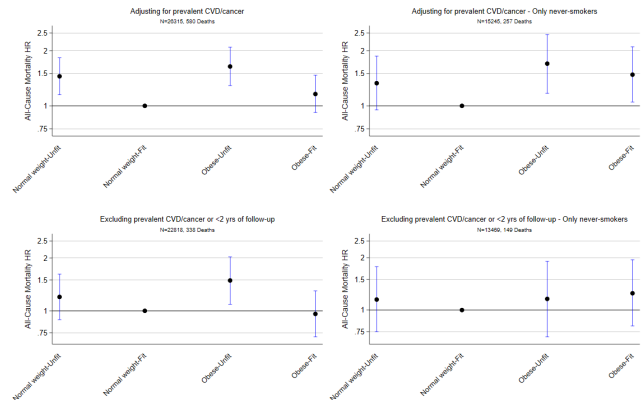

Measured cardiorespiratory fitness (CRF) with exercise testing is a powerful predictor of mortality but unfeasible in many health-care and research settings. Although non-exercise estimated CRF (NEE-CRF) has been shown to be associated with mortality outcomes, relatively small cohorts and impractical predicting variables used to estimate CRF are challenging its broad application. **PURPOSE:** To assess the association between NEE-CRF using pragmatic variables and mortality outcomes in a large prospective cohort of men and women. **METHODS:** The NIH-AARP Diet and Health Study of 330,769 participants [men (n=186,469) and women (n=144,300)] aged 50-71 years at the recruitment (1995-1996) were prospectively followed for 14.9±2.1 years until December 31, 2015. NEE-CRF was estimated using previously validated equation [34.142+1.463 (physical activity status) +0.133 (age)-0.005 (age²) +11.403 (sex)-0.254 (weight) +9.170 (height)] and analyzed for its association with mortality outcomes, utilizing multivariable Cox hazard models. **RESULTS:** During the follow up, 34,317 men and 20,295 women died from all-causes. Higher NEE-CRF was associated with lower risk of mortality due to all-causes, cardiovascular disease and cancer. For every 1-MET higher NEE-CRF there was 15%, 15%, 11% and 16%, 16%, 11% reduction in mortality risks from all-cause, cardiovascular disease and cancer, in men and women respectively. The corresponding hazards ratios and 95% confidence intervals were: 0.85 (0.84-0.86), 0.85 (0.82-0.88), 0.89 (0.87-0.91), and 0.84 (0.83-0.85), 0.84 (0.81-0.88), 0.89 (0.87-0.91) for men and women respectively (all p<0.001). **CONCLUSIONS:** Higher NEE-CRF is associated with lower risk of death due to all-causes, cardiovascular disease and cancer in a large prospective cohort. The results provide a practical implication of NEE-CRF for clinical risk stratification, referral to prevention and rehabilitation programs and utilization in large-scale epidemiological studies.

**2051 May 28 3:55 PM - 4:05 PM
 All-cause Mortality And The Fat-but-fit Hypothesis: A Reexamination Using Uk Biobank**

Jakob Tarp¹, Miguel Adriano Sanchez-Lastra², Ding Ding³, Anders Grøntved⁴, Ulf Ekkelund, FACSM¹. ¹*Norwegian School of Sports Sciences, Oslo, Norway.* ²*University of Vigo, Pontevedra, Spain.* ³*University of Sydney, Camperdown, Australia.* ⁴*University of Southern Denmark, Odense, Denmark.*
 Email: jakob.tarp@nih.no
 (No relevant relationships reported)

Obesity is associated with an increased risk of premature mortality, but observational studies implies that obese adult with high cardiorespiratory fitness (CRF; ‘fat-but-fit’) may not be at an increased risk. However, the evidence for the ‘fat-but-fit’ hypothesis is limited by insufficient control of confounding from smoking and risk of reverse-causality bias from pre-existing conditions. **PURPOSE:** To examine evidence for the ‘fat-but-fit’ hypothesis using different approaches for reducing confounding and reverse-causality bias. **METHODS:** CRF was estimated from linear extrapolation of the heart rate response during a submaximal bicycle ergometer test in women and men from the UK Biobank cohort. Watts per kg fat-free mass was split into unfit (<20%) or fit (>60%) based on the age-sex stratified sample distribution and combined with measured body-mass index (BMI) as normal weight (NW; BMI 18.5 – 25) or obese (BMI ≥ 30) yielding four CRF-BMI combinations. All-cause mortality was ascertained from death registers. Multivariable-adjusted cox-regression models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI). **RESULTS:** Over a median follow-up of 7.7 years, 580 deaths in 26,315 participants were recorded. In analysis adjusting for prevalent CVD/cancer and using NW-fit as

the reference, being NW-unfit or obese-unfit were associated with increased mortality with HRs of 1.45 (CI: 1.15, 1.83) and 1.64 (1.29, 2.09), see figure. Mortality was not increased in the obese-fit against the reference (1.16 (CI: 0.92, 1.47)). Associations were attenuated when excluding individuals with prevalent CVD/cancer and early deaths. Re-analyzing with restriction to never-smokers resulted in similar HRs across the fat-fit combinations against the NW-fit reference. **CONCLUSION:** Obese-unfit, but not obese-fit, individuals have an increased risk of premature mortality as compared with NW-fit individuals. The association appears susceptible to bias.

**2052 May 28 4:05 PM - 4:15 PM
 Association Of Physical Activity Best Practices For Early Care And Education With Time-use And Children’S Physical Activity**

Erik A. Willis, Derek Hales, Regan Burney, Falon Smith, Amber Vaughn, Dianne S. Ward, FACSM. *University of North Carolina-Chapel Hill, Chapel Hill, NC.* (Sponsor: Dianne S. Ward, FACSM)
 Email: erik.willis@unc.edu
 (No relevant relationships reported)

PURPOSE: Our goal was to estimate the time-use exchanges associated with physical activity (PA) best practices for early care and education (ECE) centers on the PA behaviors of children. **METHODS:** The Environment and Policy Assessment and Observation (EPAO) was collected on 150 classrooms from 80 child care centers along with corresponding accelerometer (ActiGraph GT3X+) data on 472 children. Data were aligned to evaluate how center activities matched with children’s sedentary and PA behaviors. EPAO data were used to assess compliance with select best practices from the Nutrition and PA Self-Assessment for Child Care: ≥60 min/d of outdoor play, ≥120 min/d of indoor/outdoor play, and <60 min/d of sedentary time. Linear mixed models were used to examine children’s PA outcomes based on compliance with best practices. Center-level models were adjusted for day of week, month, and wear time. Child-level models were additionally adjusted for child’s age, sex, and race/ethnicity. **RESULTS:** Meeting the outdoor play best practice was associated with a significant shift in centers’ time use: +56.7 min/d of outdoor play and -38.5 min/d of indoor play. Meeting this best practice was associated with ~9 min/d increase in children’s total PA. Meeting the indoor/outdoor play best practice was also associated with a shift in centers’ time use: +66.9 min/d of indoor/outdoor play, -29.7 min/d of screen/sitting, -11.4 min/d for circle time, -2.9 min/d for snack, -3.8 min/d for morning meal, and -19.2 min/d of non-classified activities. Meeting this best practice was also associated with a ~14 min/d increase in children’s total PA. Meeting the best practice for limiting sedentary time was associated with -55.0 min/d of screen/sitting, +24.4 min/d of indoor play, +15.1 min/d of outdoor play, +8.4 min/d for circle time, and +2.2 min/d for lunch. Meeting this best practice was associated with a ~7.0 min/d increase in children’s light activity, but there were no significant associations with their sedentary or moderate-vigorous PA. **CONCLUSIONS:** These results suggest that increasing time for play does not directly translate to increases in total PA. These findings suggest the need for more quality play opportunities (e.g. provider-led PA) rather than allocating time alone to improve daily PA.

THURSDAY, MAY 28, 2020

2053 May 28 4:15 PM - 4:25 PM

The Prevalence Of Meeting 2008 Versus 2018 Physical Activity Guidelines In Adults With Overweight/obesity

Danielle M. Ostendorf¹, Kate Lyden², Jan Lande³, Kristen Bing¹, Liza Wayland¹, Edward L. Melanson, FACSM¹, Victoria A. Catenacci¹. ¹University of Colorado Anschutz Medical Campus, Aurora, CO. ²PAL Technologies, Glasgow, United Kingdom. ³Bear Mountain Technologies, LLC, Golden, CO. (Sponsor: Edward Melanson, FACSM)
Email: danielle.ostendorf@cuanschutz.edu
(No relevant relationships reported)

Both the 2008 and 2018 Physical Activity Guidelines for Americans (PAG) recommend ≥ 150 min/wk of moderate physical activity (PA) for substantial health benefits and suggest many adults may need ≥ 300 min/wk of moderate PA for additional health benefits (including weight control). The 2008 PAG specified that PA be accumulated in bouts ≥ 10 minutes, however, this criteria was removed in the 2018 PAG.

PURPOSE: To determine the extent to which removing the bout criteria impacts the prevalence of meeting PAG for weight control in adults with overweight/obesity.

METHODS: Participants were 155 adults with overweight/obesity enrolled in an 18 month weight loss intervention. Baseline levels of bout and total moderate-to-vigorous PA (MVPA, SenseWear device) were used to determine proportion meeting 2008 vs 2018 PAG, and to classify subjects into 3 mutually exclusive groups: meeting 1) ≥ 300 min/wk of both bout and total MVPA (BOTH; n=28), 2) ≥ 300 min/wk of total (but not bout) MVPA (TOTAL; n=65) or 3) < 300 min/wk of bout or total MVPA (NEITHER; n=62). We also compared age, sex, BMI, body fat mass (FM, DXA), and fitness (VO_{2max}) across groups.

RESULTS: The proportion of subjects meeting 2008 (18%) vs. 2018 (60%) PAG was significantly lower ($P<0.01$). BOTH had a higher mean age vs TOTAL (mean \pm SD; 43 \pm 10 vs 37 \pm 9 y, $P<0.01$). BOTH had the lowest proportion of females, followed by TOTAL, and then NEITHER (64% vs 83% vs 94%, $P<0.01$). BOTH had a lower BMI and FM compared to TOTAL and to NEITHER (BMI: 32 \pm 3 vs 35 \pm 4 vs 36 \pm 4 kg/m², $P<0.01$; FM: 36 \pm 7% vs 41 \pm 5% vs 43 \pm 4%, $P<0.01$), with no differences between TOTAL vs NEITHER. BOTH had the highest VO_{2max} (adjusted for age and sex), followed by TOTAL, and then NEITHER (28.1 \pm 4.6 vs 25.0 \pm 4.4 vs 22.6 \pm 3.9 mL/kg/min, $P<0.01$).

CONCLUSIONS: In this cross-sectional analysis of adults with overweight/obesity, removing the bout criteria resulted in a 3 fold greater prevalence of meeting PAG for additional health benefits (including weight control). Meeting 2018 PAG (but not 2008 PAG) did not significantly differentiate between levels of BMI or FM compared to not meeting 2018 PAG. Researchers planning on using PAG for screening eligibility should be aware of the clinical health differences in adults who meet 2008 vs 2018 PAG. Prospective studies are needed to determine how removing the bout criteria impacts weight control.

Physical Activity Time Of Day And Risk Of Weight Change In Men And Women

Erika Rees-Punia, Mark A. Guinter, Susan M. Gapstur, Ying Wang, Alpa V. Patel, FACSM. *American Cancer Society, Atlanta, GA.* (Sponsor: Alpa V Patel, FACSM)
(No relevant relationships reported)

PURPOSE: Laboratory studies suggest there are potential benefits of morning vs. evening exercise on various physiologic responses in humans but results from epidemiologic and intervention studies are less consistent. The purpose of this study was to examine the association between free-living physical activity timing and change in weight over a three-year period.

METHOD: Participants (n=549, 58% women, 66% non-Latinx white) completed an accelerometer protocol for at least six days during two non-consecutive quarters in 2015 and self-reported weight in 2015 and 2018. Multinomial logistic regression was used to explore associations between the proportion of total moderate-vigorous physical activity (MVPA) achieved before noon and percent weight change (loss, gain, stable). All analyses were stratified on sex and adjusted for age, race/ethnicity, number of comorbidities, energy intake (self-reported in 2015), accelerometer wear time, sleep time, and total MVPA (to isolate time-of-day effect).

RESULTS: Participants accumulated 12-64% of their MVPA in the morning hours. Participants who accumulated more MVPA in the morning were more physically active overall (81 vs. 69 min./day MVPA Q4 vs. Q1) but were also more likely to have insufficient sleep (7.1 vs. 8.2 hr./day Q4 vs. Q1). Women accumulating most of their MVPA in the morning hours (Q4, >42%) were 1.99 times more likely to maintain their weight over three years (95% confidence interval [CI]: 0.95, 4.69). MVPA timing did not appear to be associated with weight change among men. Race/ethnicity-stratified results suggested that the associations were not different among black, Latinx, or white participants.

CONCLUSION: In addition to the impact of physical activity duration, frequency, and intensity on weight control, physical activity timing may also play a role, particularly

in women. The timing of MVPA is a fairly flexible aspect of the behavior and may confer additional benefits regarding weight control; however, more research is needed to fully understand the associations.

2055 May 28 4:35 PM - 4:45 PM

Cardiorespiratory Fitness And Muscle Strength With The Prevalence Of Diabetes: WASEDA'S Health Study

Dong Wang, Susumu S. Sawada, FACSM, Hiroki Tabata, Kumpei Tanisawa, Ryoko Kawakami, Kaori Ishii, Katsuhiko Suzuki, Mitsuru Higuchi, FACSM, Koichiro Oka, Shizuo Sakamoto. *Waseda university, Saitama, Japan.*
(No relevant relationships reported)

Limited data are available on the relationship of cardiorespiratory fitness (CRF) and muscle strength (MS) with the prevalence of diabetes. **PURPOSE:** This cross-sectional study was to investigate the independent and joint relationship of CRF and MS with the prevalence of diabetes among Japanese men in the WASEDA'S Health Study. **METHODS:** WASEDA'S Health Study is a cohort study which was launched in 2014. We used part of the baseline data collected for this study. Participants were 627 Japanese men [median (inter quartile range) age 56 (48-65) years] who completed a medical examination, leg extension power test, and graded exercise test using cycle ergometers at baseline. The participants were divided into two groups based on CRF and MS, respectively. The prevalence of diabetes was based on self-reports from questionnaires and/or blood tests at the medical examination. Odds ratios and 95% confidence intervals (95% CIs) for the prevalence of diabetes were obtained using logistic regression models while adjusting for age, body mass index, physical activity, family history of diabetes, cigarette smoking, and alcohol intake. **RESULTS:** 49 participants had diabetes. Using the lower CRF and MS as a reference, odds ratios and 95% CIs for the higher CRF and MS were 0.56 (0.26-1.21) and 0.51 (0.25-1.05), respectively. Also, using the lower CRF and lower MS group as a reference, odds ratios and 95% CIs were 0.52 (0.20-1.33) for the lower CRF&higher MS group, 0.55 (0.21-1.41) for the higher CRF&lower MS group, and 0.31 (0.12-0.79) for the higher CRF&higher MS group, respectively. **CONCLUSIONS:** These results suggest that there is a relationship between CRF and MS with the prevalence of diabetes. In addition, there is a joint relationship of CRF and MS with the prevalence of diabetes among Japanese men.

2056 May 28 4:45 PM - 4:55 PM

Joint Associations Of Occupational Standing And Occupational Exertion With Musculoskeletal Symptoms In A Us National Sample

Keith M. Diaz. *Columbia University, New York, NY.*
Email: kd2442@columbia.edu
(No relevant relationships reported)

PURPOSE: As evidence has implicated sedentary behavior as a health risk factor; initiatives to reduce workplace sitting time by replacing it with standing have received considerable interest. However, concerns have been raised that standing exposes workers to other health hazards; notably observational studies have linked occupational standing to musculoskeletal pain. These prior studies, however, are potentially flawed. For many occupations, standing at work co-occurs with high physical exertion, thus the observed associations between standing and musculoskeletal pain could be confounded by the physical exertion that accompanies many standing-based occupations. The purpose of this study was to examine the joint associations of occupational standing and occupational exertion with musculoskeletal symptoms. **METHODS:** Data for this analysis come from the 2015 National Health Interview Survey, a US nationally representative survey. Occupational standing and exertion were assessed by self-report on a 5-point Likert scale. Presence of musculoskeletal symptoms (pain, aching, or stiffness) for upper extremity (neck, shoulders, elbows, wrists, fingers) and lower extremity (hips, knees, ankles, toes) joints was also assessed. **RESULTS:** There was a significant interaction between occupational standing and occupational exertion ($p<0.05$). Occupational standing was associated with upper extremity and lower extremity symptoms only among the group with high levels of occupational exertion (Figure). Among those reporting lower levels of occupational exertion; occupational standing was not associated with upper or lower extremity symptoms. **CONCLUSIONS:** Results from this US representative survey suggest the association between occupational standing and musculoskeletal symptoms is largely driven by the co-occurrence of occupational exertion and bring into question the contention that standing in itself incurs adverse musculoskeletal symptoms.

2057 May 28 4:55 PM - 5:05 PM

Late Adulthood Physical Activity Trajectories In Relation To All-cause Mortality

Alpa V. Patel, FACSM¹, Sara E. Strollo¹, Erika Rees-Punia¹, Lauren R. Teras¹, Ying Wang¹, Corinne R. Leach¹, Janet E. Fulton, FACSM², Susan M. Gapstur¹. ¹American Cancer Society, Atlanta, GA. ²Centers for Disease Control and Prevention, Atlanta, GA. Email: alpa.patel@cancer.org (No relevant relationships reported)

PURPOSE: Despite the known benefits of being physically active, about half of U.S. adults (and nearly two-thirds of adults age 65+ years) do not meet current U.S. Physical Activity Guidelines for Americans of 150-300 minutes of moderate (75-150 minutes of vigorous) physical activity (MVPA) per week. Given the aging U.S. population and rising healthcare costs, identifying factors associated with healthy aging is critical. There is limited epidemiologic evidence examining whether increasing or initiating MVPA in later adulthood can increase longevity. This study examined the association between late adulthood MVPA trajectories and all-cause mortality in a large U.S. prospective cohort.

METHODS: This analysis included 71,862 Cancer Prevention Study-II Nutrition Cohort participants (mean age 74.1 years; range 52-89 years) who were free of major chronic diseases. Participants self-reported MVPA at two time points approximately 5-years apart and were categorized based on their level of adherence to MVPA guidelines at each time point (inactive, "insufficiently active", "sufficient", and ">double minimum recommended"). 12 trajectories were defined (4 each for consistent, increasing, or decreasing MVPA); participants who were consistently "insufficiently active" served as the reference category. Multivariable Cox proportional hazards regression modeling was used to estimate hazard ratios (HR) and 95% confidence intervals (CI).

RESULTS: After an average of 9.9 years of follow-up, 22,736 deaths occurred. The most active participants (>double recommended) at both time points had a 24% lower mortality risk compared to insufficiently active participants (95% CI 0.73-0.79). Those who increased MVPA over time (insufficient to sufficient) also had a lower mortality risk (HR=0.85, 95% CI 0.80-0.91). Conversely, those who decreased activity (sufficient to inactive) had a higher mortality risk (HR=1.18, 95% CI 1.10-1.26). Associations were similar for men and women, and for cardiovascular disease and cancer-specific mortality.

CONCLUSIONS: Maintaining a physically active lifestyle at older ages is optimal for longevity. Public health messaging should encourage active individuals to maintain their physical activity level as they age and reinforce that it is never too late to start being active.

Arterial Elasticity Response To Short-term Endurance Resistance And Blood Flow Restriction Training In Older Men

Murat Karabulut, FACSM¹, Ricardo Parra¹, Michael G. Bemben, FACSM², Ulku Karabulut¹. ¹University of Texas Rio Grande Valley, Brownsville, TX. ²University of Oklahoma, Norman, OK. Email: murat.karabulut@utrgv.edu (No relevant relationships reported)

PURPOSE: To test hemodynamic and arterial elasticity response to 8-week endurance (END) and blood flow restriction resistance training (BFR) in older men.

METHODS: Fifteen older male subjects (age= 57±4.6 yr.) were randomly assigned to one of two training groups (END, n=8 & BFR, n=9) that performed the leg press, leg extension, leg curl, chest press, lat pulldown, and biceps curl exercises 3x/wk for 8 weeks. All training sessions began with subjects warming up in a gym by walking/ jogging at their self-selected speed for 5 min. The END group performed exercise for 4 sets of 15 reps at 40-65% of one repetition maximum (1RM) with 30 sec rest between each set. The BFR group performed exercises for 4 sets of 20 reps at 20-30% of 1RM with 30 sec rest between each set. The BFR cuffs were placed on both arms (pressure ranged from 140 to 160 mmHg) or legs (pressure ranged from 160 to 200 mmHg) for the related exercises with 3-5 min rest in between upper and lower body exercises for cuff placement. Fasted subjects (for at least 8 hr.) reported to the lab and hydration level was assessed by clinical urine refractometer before testing sessions. Pre and post-training pulse wave analysis (PWA) and velocity (PWV) were measured non-invasively using SphygmoCor-Xcel.

RESULTS: One-way ANOVA did not detect any significant differences between group means for any of the hemodynamic variables at baseline. There were no significant condition main effects for any of the variables measured. However, there were significant main effects for time with the pre-test demonstrating higher values than the post-test values for aortic diastolic pressure (p< 0.04), aortic and systemic mean arterial pressure (p< 0.03), end systolic pressure (p= 0.04), and mean arterial pressure during diastole (p< 0.04). In addition, trends for significant time main effects were detected for PWV (p= 0.09), aortic systolic pressure (p= 0.06), systemic systolic and diastolic pressure (p= 0.08), systemic mean arterial pressure (p= 0.06), and pressure time index for diastolic pressure (p= 0.08).

CONCLUSIONS: The findings of the study indicate that both BFR and END resistance training programs are similarly effective in decreasing the central and systemic blood pressure that could be due to training-related adaptations in vascular function and structure.

No, Near And Far Transfer Upon Balance Training Interventions Through Lifespan: Findings From Rcts And Practical Implications

Lars Donath, German Sport University, Cologne, Germany. (Sponsor: Prof. Dr. Scott Drum, FACSM) Email: l.donath@dshs-koeln.de (No relevant relationships reported)

Task-specificity vs. task-transfer upon neuromuscular exercise training through lifespan: Practical implications derived from RCTs and meta-analytical reviews

Prof. Dr. Lars Donath & PD Dr. Oliver Faude
Department of Intervention Research in Exercise Training, German Sport University, Cologne
Department of Sport, Exercise and Health, University of Basel, Germany

Neuromuscular training can reduce injuries and falls in athletes and the aging population. However, the training responses and adaptability to different types of neuromuscular exercises are not fully elucidated.

PURPOSE: To provide an overview based on several randomized controlled trials and meta-analyses of our group with respect to training adaptation with a) lacking, b) near) and c) far transfer effects. **METHODS:** Data of more than 5000 healthy participants between the age of 8 and 80 years of age were considered. Neuromuscular performance was assessed employing static, unstable and dynamic balance testing, gait assessment and strength examination. All tests were conducted before and after the intervention period. The intervention included different types of balance training ranging from static tasks to agility tasks and lasted from 8 to 50 weeks of training. Repeated measures analyses of variance with baseline measures as covariate were computed in the RCTs and inverse variance models with random effect size estimation (Hedges g adjusted for small samples) have been conducted in the meta-analytical reviews.

RESULTS: All randomized controlled trials revealed significant (p<0.05) moderate to large effects (SMD>0.5) in the tests that are closely related to the trained exercise task. Transfer effects to other neuromuscular tasks (e.g., strength, balance) are negligible to small (SMD<0.3). These findings have been underpinned by two meta-analytical reviews. Transfer effects have been observed for some strength variables (e.g., rate of force development), performance indicators (e.g., sprint) and selected dynamic balance indices **CONCLUSION:** In order to ensure adequate and specific training adaptations, multimodal exercise programming should be carefully conducted based on complexity, challenge, background and progression, aligned with the intended training goals.

2084 Board #3 May 28 2:00 PM - 3:30 PM

Bouncing For Balance: Mini-Trampoline Training Reduces Fall Risk In Older AdultsQuinn Anderson, Sara Bergen, Rachel Breuer, Erik Hayes, Bradley J. Kendall. *Taylor University, Upland, IN.**(No relevant relationships reported)*

While CVD is the leading cause of death, falls are one of the most prominent causes of accidental mortality in older adults. Unfortunately, interventions in older adults often target either cardiovascular fitness or balance, with few utilizing exercise modalities that address both at once. One modality that has shown promising results on cardiovascular fitness and balance is mini-trampoline training. However, investigations on this modality have been limited in older adults. **PURPOSE:** To compare the effects of 6-weeks of mini-trampoline training to 6-weeks of walking on fall risk and functional fitness in older adults. **METHODS:** Twenty participants (mean age 72±6.9) completed six weeks (3 sessions/week) of trampoline training consisting of aerobic (e.g., jumping jacks) and balance (e.g., tandem skips) exercises, all of which took place on a mini-trampoline. Each session was led by a trained research staff member. For comparison, a control group (n=18, mean age 66±7.4) participated in an unmonitored walking program for six weeks (3 sessions/week) with a goal of increasing average step count by 100 steps every week. At the start and conclusion of the intervention, all participants were assessed on measures of balance (i.e., fall risk and single-leg stands), mobility (i.e., 4-square step test and 8-foot up-and-go), and aerobic endurance (i.e., 6-minute walk test). **RESULTS:** Due to significant differences between the groups at baseline, change scores were calculated for all measures and were compared using independent samples t-tests. Following training, the trampoline group significantly reduced fall risk $t(36) = 2.129, p < .05, d = .87$, increased single-leg stand time, $t(36) = 7.04, p < .01, d = .87$, and decreased 4-square step test time $t(36) = 2.651, p < .05, d = 1.5$ compared to the walking group. Both groups decreased their 8-foot up-and-go times and increased 6-minute walk distance after the six weeks. However, change scores were not statistically different between the groups ($p > .05$). **CONCLUSION:** As a result of this study, it appears that mini-trampoline training is a viable exercise modality for older adults to reduce fall risk and improve balance while providing similar cardiovascular benefits (i.e., improvements in walking distance) to those as a result of walking.

2085 Board #4 May 28 2:00 PM - 3:30 PM
Comparison Of The Effects Of Two Different Resistance Training Programs On Strength In Older MalesRicardo Parra, Murat Karabulut, FACSM. *University of Texas - Rio Grande Valley, Brownsville, TX.**(No relevant relationships reported)*

PURPOSE: The purpose of this study was to compare the effects of 8 weeks of blood flow restriction (BFR) training and traditional endurance resistance training on isotonic, isokinetic, isometric strength in older males. **METHODS:** A total of 17 males (57.0 yr ± 4.6 yr) completed the study. Subjects were randomly assigned to two training groups: blood flow restriction (BFR; n = 9) or endurance resistance training (END; n = 8). Prior to exercise training, baselines measurements were recorded, including height, weight, one repetition maximum (1RM), and unilateral knee extension testing to determine maximal voluntary contraction (MVC) and isokinetic torque at 60°/sec and 180°/sec. Training was held three times a week in a training room under laboratory settings and under the supervision of an experienced and certified strength and conditioning specialist, who ensured that subjects used proper exercise form and provided verbal encouragement. The following machine-based exercises were performed: Leg press, leg extension, leg curl, chest press, and shoulder press. Following a warm-up consisting of a 5-minute walk or jog, the BFR group performed 4 sets of 20 repetitions of the 5 exercises at 20-30% 1RM, while the END group performed 4 sets of 15 repetitions of the 5 exercises at 40-65% 1RM, with 30-60 seconds of rest between exercises. Cuffs were placed at the upper most portion of the limbs. Initial cuff tightness was kept between 30 and 40 mmHg for upper and lower limbs, and final pressure of the cuffs was between 140 to 160 mmHg for upper body 160 to 200 mmHg for lower body. BFR group rested 3-5 minutes between upper and lower body exercises. Following completion of the 8-week training, the measurements at baseline were re-recorded. **RESULTS:** One-way ANOVA resulted in no difference between groups at baseline. Time main effects were seen in 1RM ($p \leq .05$), isokinetic torque at 60°/sec ($p \leq .05$) and 80°/sec ($p \leq .05$), and MVC ($p \leq .05$) tests. **CONCLUSION:** The BFR and END training protocols resulted in similar results on improving strength after 8 weeks of resistance training. It could be speculated that even though half the weight was lifted during the BFR sessions compared to the END sessions, the BFR-related local and systemic changes elicited similar improvements in isotonic, isokinetic, and isometric strength in older males.

2086 Board #5 May 28 2:00 PM - 3:30 PM

The Impact Of Verification Phase Intensity For Determination Of VO₂max In Older AdultsJared M. Dickinson, FACSM¹, Ian R. Villanueva², John N. Campbell², Serena M. Medina², Theresa M. Jorgensen², Shannon L. Wilson², Nathan Serrano², Siddhartha S. Angadi, FACSM², Glenn A. Gaesser, FACSM². ¹Arizona State University and ²Central Washington University, Ellensburg, WA. ²Arizona State University, Phoenix, AZ.*(No relevant relationships reported)*

Maximal oxygen uptake (VO₂max) declines with age and is a strong predictor of morbidity and mortality risk. Thus, accurate assessment of VO₂max is important for the older population. **PURPOSE:** To evaluate the use of a verification phase performed at different intensities for determination of VO₂max on a stationary cycle ergometer in older adults. **METHODS:** Twenty-two older adults (67±6 yr; 26.3±5.1 BMI) were recruited to participate in the study. Each subject completed two experimental trials in a randomized, counterbalanced cross-over design. Both trials consisted of an identical traditional ramp test, followed by 10 min of active recovery, and a verification phase performed at either 85% (VP85) or 110% (VP110) of the peak work rate achieved during the ramp. Expired gases and heart rate (HR) were continuously monitored throughout each test. VO₂peak was determined using the highest 30-sec average. **RESULTS:** No significant differences were observed for absolute (L/min) VO₂peak between VP85 (1.86±0.72; P=0.679) or VP110 (1.79±0.73; P=0.200) and the associated ramps (1.85±0.73 and 1.82±0.72, respectively). There was also no significant difference in maximal HR (bpm) between VP85 (153±17; P=0.243) or VP110 (146±16; P=0.085) and the associated ramps (150±17 and 149±16, respectively). However, individual data indicated that 36% of subjects achieved a ≥2% greater VO₂ (L/min) during the VP85 compared to the ramp, while only 15% of subjects achieved a ≥2% greater VO₂ (L/min) during the VP110 compared to the ramp. Moreover, the trend of a decreased percentage of subjects achieving a higher value compared to the ramp during VP110 as compared to the VP85 was fairly consistent across all physiological data (using the collected coefficient of variation [CV] data). While no significant differences (P>0.05) were found for most variables between the two ramp tests, 40% of subjects achieved a VO₂ (L/min) during the second ramp test that was higher than the CV between ramp tests. **CONCLUSION:** These data suggest that if a verification phase is employed for VO₂max assessment in otherwise healthy older adults, a power slightly below peak work rate may provide a more accurate assessment compared to a power slightly above peak work rate. Supported by intramural funds from ASU

2087 Board #6 May 28 2:00 PM - 3:30 PM

Assessment Of Cardiorespiratory Fitness In Older Adults With Cognitive ImpairmentShirit Rosenberg, Hallie Nuzum, Heather Taylor, Peter Louras, J. Kaci Fairchild. *Palo Alto Veterans Health Care System, Los Altos, CA.* (Sponsor: Dr. Jonathan Myers, FACSM)
Email: shiritkamil@gmail.com*(No relevant relationships reported)*

Interest in the potential benefits of physical activity (PA) and exercise on cognition in late life has grown exponentially in the past decade. Peak oxygen uptake (VO₂) is one of the most widely used metrics of physical fitness. The most accurate measure of VO₂ is cardiopulmonary testing (CPX); however, this method may not be easily accessible in many settings nor appropriate for all populations, including older adults. Self-report measures of PA are easily administered and readily available, yet these measures rely on an accurate recall of past activity. This may be difficult for older adults with even mild forms of cognitive impairment. Identifying alternative methods that accurately estimate a patient's physical fitness are essential.

PURPOSE: To evaluate the use of multiple measures of physical fitness in a sample of older adults with amnesic Mild Cognitive Impairment (aMCI).

METHODS: The sample included 105 older adults who were diagnosed with aMCI (93.3% male, aged = 71.2 ± 9.2 years). Measures of physical fitness included CPX, 6-minute walk test (6MWT), and the Yale Physical Activity Survey (YPAS). Analysis included comparison of the sub-maximal measures of physical fitness (6MWT) and self-report measures (YPAS) with directly-measured cardiorespiratory fitness on key measures on physiologic measures of fitness (e.g., peak VO₂, resting blood pressure (BP), BMI).

RESULTS: The 6MWT demonstrated a stronger correlation with directly-measured peak VO₂ ($r = 0.62, p = 0.00$) compared to YPAS. The YPAS activity dimensions summary index (composed of questions on vigorous activity, leisurely walking, moving, sitting, and standing) correlated marginally with VO₂max ($r = 0.28; P = 0.01$). The YPAS index of vigorous activity was slightly correlated with VO₂max ($r = 0.21; P = 0.03$). CPX was inversely correlated with BMI ($r = -0.21; P = 0.03$) and non-significantly with resting BP. Resting BP and BMI was not significantly associated with 6MWT nor the YPAS indices.

CONCLUSION: The present analysis suggests that even mild forms of cognitive impairment impact the validity of self-report measures of physical fitness. Sub-maximal tests of aerobic capacity, such as the 6MWT, provide more accurate estimates of cardiorespiratory fitness and are easily administered in a variety of settings in which older adults receive health care.

2088 Board #7 May 28 2:00 PM - 3:30 PM
Physical Fitness In Older Adults: Is There A Relationship With The Modified Functional Movement Screen?

Martin S. Dietze-Hermosa, Samuel Montalvo, Matthew P. Gonzalez, Alondra Rodriguez, Ileana Jarquin, Sandor Dorgo. *The University of Texas at El Paso, El Paso, TX.*
 (No relevant relationships reported)

There is an increasing emphasis on maintaining and improving physical function and capacity in older adults. Measures obtained through physical fitness testing can help provide health/fitness practitioners with important information used to structure the exercise and rehabilitation programs prescribed for older adults. The modified Functional Movement Screen™ (mFMS) has been utilized as a tool to screen for movement proficiency, stability, motor control and balance in older adults. Yet, its relationship to other measures of physical fitness is not yet fully understood. **PURPOSE:** Determine the relationship between mFMS scores and measures of physical fitness in older adults. **METHODS:** In total, 78 older adults (36 males and 42 females; mean age \pm SD: age 69.00 \pm 7.61 years) completed this cross-sectional study. Physical tests included: handgrip strength (HG), back-leg strength dynamometer (BLS), 8 ft. Up-and-Go (8UG), vertical jump (VJ), medicine ball throw (MBT), chair stand (CST), arm curl (AC), and 6-minute walk (6MW). Participants also completed the mFMS which consists of 4 screens: Shoulder Mobility Screen (SMS), Deep Squat (DS), Active Straight Leg Raise (ASLR), and Lower Body Motor Control Screen (LB-MCS). Scoring criteria ranges from (0-3) for the SMS, DS, and ASLR screens, with higher scores indicating better performance. The LB-MCS is scored as pass/fail. Spearman's *R* correlations were conducted to determine associations between physical fitness tests and the mFMS. **RESULTS:** The DS was significantly correlated with all fitness tests ($p < 0.05$). Specifically, higher DS scores were associated with improved HG ($r = 0.29$), BLS ($r = 0.50$), VJ height ($r = 0.51$), MBT ($r = 0.41$), CST ($r = 0.56$), AC ($r = 0.29$), 6MW ($r = 0.53$), and 8UG ($r = -0.64$) performance. Lastly, better 8UG ($r = -0.35$), BLS ($r = 0.32$), and 6MW ($r = 0.29$) performance were associated with individuals who passed the LB-MCS ($p < 0.05$). No other screens were significantly associated with physical fitness tests. **CONCLUSION:** Increased DS scores and passing the LB-MCS may contribute to overall improvement of physical fitness in older adults. Health practitioners desiring to increase measures of physical fitness in older adults and who use the mFMS as a screening tool may want to focus on increasing DS and LB-MCS movement proficiency.

The Relationship Between Hip Displacement In The Anteroposterior Direction And Life-space Mobility Among Older Women

Shunsuke Yamaji¹, Kosho Kasuga², Tamotsu Kitabayashi³.
¹University of Fukui, Eiheiji Fukui, Japan. ²Gifu University, Gifu, Japan. ³Tokyo University of Science, Tokyo, Japan.
 (Sponsor: Kiyoji Tanaka, FACSM)
 Email: yamaji@u-fukui.ac.jp
 (No relevant relationships reported)

PURPOSE: The ability to recover one's balance using a hip-based strategy is important to avoid falls, but many older adults have limited hip flexibility. This study aimed to clarify the relationship between hip displacement during voluntary motion (Hip-D) in the anteroposterior direction and life-space mobility, and to examine whether Hip-D could be used to independently distinguish the quality of one's life-space mobility by comparing the results on the Life-Space Assessment (LSA) scale. **METHODS:** Hip-D and physical functions related to fall prevention were measured in 319 community-dwelling older women. Hip-D was defined as the maximum moving distance of the great trochanter in the anteroposterior direction. The participants were also classified into good and poor life-space mobility groups based on their LSA scores. The ability of the Hip-D and physical functioning tests to distinguish the above groups was determined using DeLong's test of the area under the receiver operating characteristic curve (AUC) for each test. **RESULTS:** Hip-D was significantly greater in the good life-space group (25.2 \pm 6.9 cm) than in the poor life-space group (17.3 \pm 5.1 cm). The LSA score was moderately correlated with Hip-D ($r = 0.51$, $p < 0.05$) but only weakly with the fall-related physical functioning parameters ($|r| = 0.15-0.39$). Hip-D had the highest AUC (0.824, 95%CI: 0.776-0.872) among all parameters, and the Hip-D cutoff value was 20.9 cm. The AUC for Hip-D was significantly greater than those for all fall-related physical functioning parameters (AUC = 0.591-0.754) in an examination based on DeLong's test. **CONCLUSIONS:** Hip-D measurements of older adults were easy to obtain and were moderately correlated with life-space mobility.

As such, this approach represents a useful way to predict life-space mobility. Hip-D measurements proved to be more reliable for this purpose than the other fall-related physical functioning parameters studied. It will be necessary the care prevention exercise to improve Hip-D (at least over 21 cm) for older adults.

Validity And Reliability Of Walk Tests For Cardiopulmonary Fitness In The Elderly According To Distances And Time To Walk

Soo Min Lee, Yeon Soo Kim, Ho Yong Sung. *Seoul National University, Seoul, Korea, Republic of.*
 Email: sumsum2ya@snu.ac.kr
 (No relevant relationships reported)

Abstract

Background and Purpose: Cardiopulmonary Fitness is one of health fitness factors, and it correlates chronic disease incidence and mortality in terms of cardiovascular diseases, hypertension, and diabetes. Walk test is commonly used to maintain physical function for CF of the elderly in their daily lives. The most commonly used walk tests are 6MWT (6 minute walk test) at a 30m straight line suggested by ATS (American Thoracic Society) and 20m walk test suggested by the SFT (Senior Fitness Test). However, both tests need long hallway and big space. The purpose of this study was to assess the validity and reliability of walk tests to estimate CF for elderly according to distances and time to walk.

Methods: 57 subjects without any disease were recruited from community site. Over 2 or 3 days, 57 subjects performed three CF tests. First test was sub-maximal exercise test on treadmill using modified Bruce protocol. Second test was 10min walk test at 20m straight line. Third test was 10min walk test at 30m straight line. In walk tests, distance was measured for 2, 4, 6, 8, and 10min. Mean and SD were calculated to describe the data. For validity of the test, the Pearson correlation coefficient was used to compare VO_{2max} (kg/min/kcal) to distances. Multiple regression analysis was conducted to develop several Equations for predicting VO_{2max} were developed by multiple regression analysis through gender, age, BMI and distance to walk. Win SPSS 25.0 was used for statistical analysis and significance level was $p < 0.05$.

Results and discussion: The results of walk tests were moderately correlated with VO_{2max} (0.64 $< r < 0.66$, $p < 0.05$). The model from 20m course at 6mins explained 48% of VO_{2max} . In addition, the model from 30m course at 2mins explained 47% of VO_{2max} . According to these results, both walk tests were moderately correlated with VO_{2max} . **Conclusions:** The feasibility of walk test for estimating CF of the elderly was confirmed to be highly positive correlated with VO_{2max} . In the 20 meter, straight distance model explained 47% of the variability in VO_{2max} . And in the 30 meter, straight distance model explained 48% of the variability in VO_{2max} . As the result, CF of the elderly can be estimated by walk test regardless of its distance and time.

Keywords: Walk Test, Cardiopulmonary Fitness Test, Validity, Reliability

Accelerometer-determined Physical Activity And Functional Fitness In Community-dwelling Older Japanese Women

Tomoaki Sakai¹, Takahiro NAKANO¹, Kosho KASUGA², Kazuo OGURI³, Syunsuke YAMAJI⁴, Tamotsu KITABAYASHI⁵, Catrine Tudor-Locke, FACSM⁶. ¹Nagoya Gakuin University, Seto, Aichi, Japan. ²Gifu University, Gifu, Japan. ³Gifu Shotoku Gakuen University, Gifu, Japan. ⁴Fukui University, Fukui, Japan. ⁵Tokyo University of Science, Tokyo, Japan. ⁶University of North Carolina at Charlotte, Charlotte, NC. (Sponsor: Catrine Tudor-Locke, FACSM)
 Email: tsakai@ngu.ac.jp
 (No relevant relationships reported)

PURPOSE: The proportion of elderly people in Japan's population now exceeds 28%, identifying the country as a "super-aging society." It is important for people to maintain health and independence as they age. Therefore, it is important for them to maintain functional fitness. The purpose of this study was to analyze the associations between accelerometer-determined physical activity and clinical measures of functional fitness. **METHODS:** One hundred ninety-nine community-dwelling Japanese women (age: 68.9 \pm 4.8 years, BMI: 22.4 \pm 2.8) wore an Active Style Pro HJA-350IT accelerometer for five weeks (Omron Healthcare Co., Ltd, Japan) on their waistline for the entire day, except when bathing, showering, swimming, or sleeping. The instrument measured the daily number of steps and accumulated time (minutes) spent in sedentary behavior (SB: < 1.5 metabolic equivalents or METs; 1 MET=3.5 ml/kg/min), light-intensity physical activity (LPA: 1.5 to 2.9 METs), and moderate- and vigorous-intensity physical activity (MVPA: ≥ 3.0 METs). Common functional fitness measures included hand grip, sit-up, sit and reach, functional reach, chair stands, 10-m walk, 10-m obstacle walk, and timed up and go. Functional fitness of participants was compared according to quartiles of steps/day and time spent in SB, LPA, and MVPA.

These quartiles are denoted as Q1 (lowest activity quartile), Q2, Q3, and Q4 (highest activity quartile). RESULTS: Participants accumulated (median, [IQR]) 6,939 [5,000-8,896] steps/day, 286.1 [228.0-349.7] SB min/day, 451.1 [398.1-509.3] LPA min/day, and 68.9 [45.7-93.0] MVPA min/day. The 10-m walk, 10-m obstacle walk, and timed up and go measures differed significantly across the steps/day quartiles (Q1<Q2, p<0.05) and MVPA quartiles (Q1<Q2, Q3, Q4, p<0.05). The 10-m walk (Q1<Q2, p<0.05), timed up and go (Q1<Q2, p<0.05), and functional reach (Q2, Q3> Q4, p<0.05) measures differed significantly across SB quartiles. There were no differences observed across LPA quartiles. CONCLUSIONS: Accelerometer-determined physical activity, especially time in MVPA, was associated with a number of different functional fitness measures.

Functional Assessment Of Older Adults: Inter-rater Reliability Of Rapid Stepping And Weight-shifting Tests
 Brandi Row Lazzarini, Shay Hannigan-Luther. *Willamette University, Salem, OR.*
Email: brow@willamette.edu
 (No relevant relationships reported)

The control of both rapid stepping movements and medial-lateral (ML) motion during standing balance and locomotion becomes increasingly difficult with aging. This aspect of function can be an early indicator of fall risk in older adults, but the ability to measure this in the clinic is limited. This analysis is part of a project to develop a clinically-feasible test of rapid stepping performance that challenges medial-lateral motion in older adults. **PURPOSE:** To determine the inter-rater reliability for three tests challenging rapid stepping performance and ML control of weight-shifting motion. **METHODS:** Older adults aged 70-96 yrs performed three rapid stepping tests: 1) the Step in Place test (SIP, n = 43) where participants stepped in place as fast as safely possible until reaching 20 footfalls of the first stepping foot, 2) the Repeated Alternating Stair Touch Test (RASTT, n = 37) where participants tapped, alternating right and left, with the ball of each foot a centered piece of tape on the top front edge of a small step as fast as safely possible for 20 s, and 3) the modified-RASTT (n = 37) which differed from the RASTT with the foot taps aimed straight forward on the step. Observations (# of steps for the RASTT tests, and time (s) for SIP) were compared between two experimenters rating one trial from each participant using independent, two-tailed t-tests, Pearson (r) correlations, and intra-class correlations (ICC) for the two RASTT tests. Given its non-normal distribution, a Spearman Rank (rho) test and a two-tailed Mann-Whitney U test were used to compare the SIP test results between raters. **RESULTS:** There was no difference between raters for the RASTT (mean [SD]: 22.9 [6.8] vs. 22.8 [6.9] steps, p = 0.194), the modified-RASTT (mean [SD]: 23.3 [7.3] vs. 23.2 [7.2] steps, p = 0.168), or the SIP (median [IQR]: 10.7 [8.6] vs. 10.8 [8.6] s, U = 912, p = 0.920). The two experimenters' ratings were highly correlated for both the RASTT (r = 0.998, ICC = 0.998), the modified-RASTT (r = 0.994, ICC = 0.993), and the SIP (Spearman's rho = 0.997). **CONCLUSIONS:** Our results indicate that these tests exhibit high inter-rater reliability.

Efficacy Of 6-week Suspension Training Exercises On Fitness Components In Older Adults
 Christina Pierle, Wayland Tseh, Michel Heijnen, Alex McDaniel. *UNCW, Wilmington, NC.*
 (No relevant relationships reported)

PURPOSE: To determine the efficacy of a 6-week suspension training exercises on fitness components in older adults.
METHODS: Three male and eight female volunteers (Age = 80.0 ± 4.9 yrs; Height = 166.3 ± 9.5 cm; Body Mass = 71.2 ± 4.9 kg; Body Fat = 34.2 ± 2.6 %) participated in the 6-week suspension training program. Pre- and post-fitness assessments comprised of handgrip dynamometer, functional reach, and overall balance. The 6-week suspension training intervention required individuals to perform a variety of exercises on the suspension training system for forty-five minutes, twice per week. A paired sample t-test was used to determine differences from pre to post (p ≤ 0.05).
RESULTS: Data revealed no significant difference between pre- and post-body fat (34.2 ± 2.6 % vs 34.3 ± 2.8 %) or handgrip dynamometer (22.4 ± 1.9 kg vs 22.8 ± 1.8 kg). There was, however, a statistical improvement from pre- to post in functional reach (57.2 ± 6.4 cm vs 68.6 ± 4.3 cm; p = 0.02) and overall balance score (67.5 ± 2.4 vs 72.2 ± 2.2; p = 0.02).
CONCLUSIONS: A 6-week suspension training exercise program was adequate to enhance core stability and overall balance amongst older adults.

Relationship Between Ecg Abnormalities And Senior Fitness Test Performance In Older Adults
 Lauren Adlof, Corey Grozier, Benny Segovia-Ruiz, Kayla Stokes, Savannah Jordan, Amy Crawley, Ludmila Cosio-Lima, FACS.M. *University of West Florida, Pensacola, FL.*
 (No relevant relationships reported)

Background: ECG abnormalities in older adults are associated with high risk of coronary heart disease and subsequent cardiac events. Cardiorespiratory fitness (CRF) is an important predictor of mortality in older adults. CRF is impacted by loss of mobility, strength, and function leading to increased risk of mortality in the elderly. The Senior Fitness Test (SFT) is a functional measure of strength, aerobic endurance, flexibility, and agility/balance in older adults. ECG testing may be related to SFT performance, and may indicate deficits in CRF or functional capacity. Understanding the relationship between ECG abnormalities and SFT performance may aid in prescribing safe, effective exercise programs for this population. **Purpose:** The purpose of this pilot study was to measure the relationships between 12-Lead resting ECG data and SFT performance in male and female older adults. **Methods:** Anthropometrics, BP, resting HR, 12-lead resting ECG, and SFT measurements were taken in 30 older adults (Age: 71.9±7.69yrs; Height: 65.81±3.39 in; Weight: 174.55±64.61lbs; BMI: 28.4±5.59kg/m²). SFT performance and ECG abnormalities were recorded, and relative VO₂ was calculated. Relationships were analyzed using chi square statistics and Pearson's correlations. **Results:** ECG abnormalities were present in 57% of this population, but no significant relationship between abnormal ECG and age, gender, VO₂, or SFT performance was found. There was a significant positive association between 30-sec chair stand (lower body strength) and 30-sec arm curl (upper body strength) performance (r=.73, p=.000), and between the 8-ft up and go (agility) and 6-min walk (CRF) distance (r=.77, p=.000). There was a significant inverse relationship between 30-sec chair stand (lower body strength) and 8-ft up and go (agility) time (r=-.69, p=.000). **Conclusion:** The presence of ECG abnormalities in over half of this population did not correlate with poor CRF or SFT performance. Lower body strength was associated with higher CRF and agility/balance, regardless of gender, age group, or ECG. Presence of ECG abnormalities may not have a negative effect on SFT performance, and older adults should be encouraged to participate in a supervised exercise program to prevent frailty and loss of independence.

Senior Fitness Test Performance Vs. Norms In Older Adults: A Pilot Study
 Corey Grozier, Benny Segovia-Ruiz, Savannah Jordan, Kayla Stokes, Lauren Adlof, Amy Crawley, Ludmila Cosio-Lima, FACS.M. *University of West Florida, Pensacola, FL.* (Sponsor: Ludmila Cosio-Lima, FACS.M.)
 (No relevant relationships reported)

Background: Functional capacity and independence in older adults is affected by mobility limitations, strength deficits, and loss of function, all of which can lead to frailty and mortality in older adults. This physical decline can be attenuated by early detection of functional limitations. The Senior Fitness Test (SFT) measures functional strength, aerobic endurance, flexibility, and agility/balance in older adults. **Purpose:** The purpose of this pilot study was to examine SFT functional performance scores in comparison to criterion-referenced population norms in male and female older adults. **Methods:** Anthropometrics, BP, resting HR, and SFT measurements were taken in 30 older adults (Age: 71.9±7.69yrs; Height: 65.81±3.39 in; Weight: 174.55±64.61lbs; BMI: 28.4±5.59kg/m²). SFT scores were recorded, and relative VO₂ was calculated. Performance scores were compared to norms and percentile ranks based on age group and gender. Relationships were analyzed using 2-way ANOVA. **Results:** In this sample, a higher BMI was significantly related to upper body strength(p=.007), but not lower body strength. There were no significant differences in SFT scores or relative VO₂ based on age group or gender. Almost all age groups and genders were classified as "average" or "above average" in comparison to SFT norms for all tests. Only males <64yrs scored below average (10th percentile) on the 6-min walk test. There were no significant differences between this population and SFT normative data. **Conclusion:** Overall, results indicated that age and gender were not significantly related to lower SFT performance, CRF, or function in tasks of daily living. However, a higher BMI was significantly related to higher upper body strength. SFT scores can be used to track functional physical ability in older adults and may be beneficial prior to beginning a supervised exercise program.

Using Virtual Reality To Improve Postural Stability In Elderly Women

Grzegorz Juras, Anna Brachman, Wojciech Marszalek, Anna Kamieniarz, Justyna Michalska, Michal Pawlowski, Kajetan Slomka. *Academy of Physical Education, Katowice, Poland.*
 Email: g.juras@awf.katowice.pl
 (No relevant relationships reported)

PURPOSE: To observe through objective testing using an assessment module incorporated in a new virtual reality (VR) system whether elderly people's static and functional balance is improved by VR balance training program that is based on movements performed in everyday life.

METHODS: Thirteen healthy elderly women participated in 12 sessions of balance-based VR training (three times a week, 30 minutes per session). The system used combined a posturographic platform with a 3D measurement system based on time-of-flight cameras (Kinect). All objective outcomes: the quiet standing test, Functional Balance Test (FBT) and limit of stability (LOS) test were measured on 3 occasions: before the intervention, after 6 training sessions and after the completion of the 4-week program.

RESULTS: Results showed significant improvement in LOS performance after the intervention. In FBT participants exhibited significant decrease ($p < .01$; Kendall's $W = 0.5$) in the average time to target hit after 6 trainings. The average center of pressure velocity increased after 6 and 12 sessions, however, did not reach significance ($p = .053$), nevertheless, the effect size was large ($\eta^2 = 0.22$). Movement optimization in FBT and parameters of quiet standing test were not significantly affected by training.

CONCLUSIONS: These results demonstrate that even a relatively short 4-week training period can bring positive outcomes. 12 training sessions of balance VR training using the force platform and Kinect sensor resulted in significant improvement of postural stability in healthy elderly women. This trial supports the potential therapeutic use of VR training program which is based on movements performed in everyday life.

2097 Board #16 May 28 2:00 PM - 3:30 PM
Effects Of Jump Training On Postural Balance And Leg Muscle Function In Healthy Older Adults

Toshiaki Nakatani¹, Kazufumi Terada¹, Hiroki Matoba¹, Masakazu Nadamoto². ¹Tenri University, Nara, Japan. ²St. Andrew's University of Education, Osaka, Japan.
 Email: toshiaki@sta.tenri-u.ac.jp
 (No relevant relationships reported)

Age-associated loss of skeletal muscle strength and postural balance are critical determinants of independent daily living activities in later life. **PURPOSE:** This study aimed to investigate the effects of different jumping exercise tempos on static balance and leg muscle function in healthy older adults. **METHODS:** Twenty-six community-living older adults were randomly assigned to a quick 108 per minute tempo (QJ; $n = 14$; 6 men) or slow 60 per minute tempo [AS1] (SJ; $n = 12$; 5 men) jumping exercise group. Both groups performed one set of jumps until they reached a level of exertion they perceived as difficult (Borg-RPE Scale of 15). Both groups trained three times a week for 12 weeks and participated in 60-min supervised group exercise sessions at a local health center. Outcome measures included center of foot pressure (CoP) sway parameters during quiet standing with eyes open (EO) and eyes closed (EC), four-square step (FSS), two-step stride length (TSL), and rate of force development (RFD) for vertical ground reaction force in sit-to-stand movement. **RESULTS:** Repeated-measures analysis of variance showed a significant main effect for FSS ($P = 0.009$) and TSL ($P = 0.002$). After the training period, QJ demonstrated a significantly decreased FSS time (5.17 ± 1.00 vs. 4.87 ± 1.00 s, $P < 0.05$) and SJ demonstrated a significantly increased TSL (210.8 ± 21.1 vs. 227.3 ± 27.2 cm, $P < 0.05$). Both groups showed no changes in CoP sway parameters with EO or EC in quiet standing. **CONCLUSIONS:** Jumps at a quick tempo improved dynamic standing balance evaluated by the FSS, while jumps at a slow tempo improved leg muscle strength. Thus, 12 weeks of jump training at different tempos appeared to have no effects on quiet standing balance, but different effects on dynamic standing balance and leg muscle strength in healthy older adults. [AS1]The phrase 'per minute' was included for one group only, but the meaning was not clear. Please check my suggested alterations.

2098 Board #17 May 28 2:00 PM - 3:30 PM
Effects Of Water-based Detraining/re-training On Muscular Fitness And Functional Capacity In Elderly People

Joao P. Botero¹, Henrique F. Rodrigues¹, Caio M O Terra¹, Bryan Haddock, FACSM², Wagner L. do Prado². ¹Federal University of São Paulo, Santos, Brazil. ²California State University, San Bernardino, CA. (Sponsor: Bryan Haddock, FACSM)
 Email: jpbotero@yahoo.com.br
 (No relevant relationships reported)

The positive long-term effects of exercise training on health-related outcomes in elderly people as well as the negative effects of training interruption are well documented. Despite largely used, little is knowing about the effects of detraining/re-training in water-based exercise training.

PURPOSE: To evaluate the effects of water-based detraining/re-training on low limb peak torque and functional capacity in an elderly population.

METHODS: One hundred and eighty-nine older individuals (68±6yrs) from both genders (176 female and 13 male) engaged in water-based training (training period = 6±3yrs), had their lower limb peak torque (dynamometer), functional capacity (Time Up and Go test [TUG]; and 6-min walk test [6WT]) assessed before exercise training interruption (TI), after 12-weeks of interruption (DT) and after 12-weeks of re-training (RT) on water-based strength training (45minute per session twice a week).

RESULTS: Lower limb peak torque decreased from TI (12.83 ± 3.86 kg/f) to DT (10.78 ± 3.66) ($p < 0.01$), and was increased after RT (17.37 ± 4.35 kg/f) ($p < 0.01$), achieving higher values compared to TI ($p < 0.01$). No effects of detraining were observed for both 6WT or TUG ($P > 0.05$), however re-training increases the performance on 6WT (425.94 ± 65.30 m) and TUG (6.84 ± 1.50 sec) compared to the TI (6WT = 390.00 ± 55.47 m; TUG = 9.71 ± 1.91 sec; $p < 0.01$, for all).

CONCLUSIONS: Detraining decreases muscle strength, but does not affect functional capacity. Water-based re-training induces additional improvements on muscle low limb peak torque and functional capacity in elderly people previously engaged in water-based training.

2099 Board #18 May 28 2:00 PM - 3:30 PM
How Age Range Affect Energy Expenditure And Exercise Efficiency Among Older People During Cycling

Keyi Yin, Wei Zhuang, Leichao Liang, Yu Liu. *Shanghai University of Sport, Shanghai, China.*
 Email: yky0504@outlook.com
 (No relevant relationships reported)

The reduced cardiorespiratory function and muscle performance in the elderly significantly minimize an individual's functional aerobic capacity. Any further decline may make them unable to complete daily activities and then have a negative influence on living independently.

PURPOSE: the purpose of this study was to examine the influence of age on changes in energy cost in two significantly different age elderly groups and one young counterpart group.

METHODS: The investigation was conducted on 30 healthy women in stationary cycling. Participants were stratified by age into young adults (Y; 20-25 years), older adults (OD; 60-65 years) and the more older adults (OU; 66-70years) with the same sample size.

The position on the cycle ergometer was adjusted for each participant. The protocol started with a rest metabolism test using a calibrated K4b² in which subjects were sitting on the cycle ergometer quietly. Then followed by a familiarization process. During the cycling test, each participant performed eight different 300-second trials. Eight trials were under the combination of 2 power output (60 and 100 Watts, W) and 4 cadences (self-selected, 40, 60 and 90 rotations-per-minute, rpm). Oxygen consumption (ml/min) and energy expenditure (EE, kcal/min) were calculated during the last 3 min of each testing condition.

RESULTS:

1. $\dot{V}O_2$ Outcomes
 Gross $\dot{V}O_2$ and net $\dot{V}O_2$ had a similar pattern. $\dot{V}O_2$ at 100 W output power was larger than those at 60 W of each age group ($p < 0.05$). However, for the same level of output power, only $\dot{V}O_2$ parameters in the Y group ($M_G = 1916.40$ and $M_N = 1606.96$) were significantly higher than those in the OU group ($M_G = 1577.88$ and $M_N = 1279.05$) at 100 W output power ($p < 0.05$).

2. EE outcomes

The age*power interaction effect on gross EE and net EE was significant, which were $F(2, 27) = 4.07$, $p = .029$ and $F(2, 27) = 3.73$, $p = .037$, respectively. Similarly, The interaction effect of age*cadence was significant with respect to gross EE and net EE, which were $F(6, 81) = 2.36$, $p = .038$ and $F(6, 81) = 2.66$, $p = .021$, respectively.

CONCLUSION:

Based on the above findings, the small change of age range would significantly affect the body energy cost during cycling. In view of oxygen consumption and energy cost, the choice of power output and cadence should be mainly considered in older adults, especially for the age ≥ 66 yrs individuals.

2100 Board #19 May 28 2:00 PM - 3:30 PM
Resistance Training Increases Insulin-Like Growth Factor-1, Strength, Physical Function, And Mental Flexibility In Female Older Adults

Luis C. Solano-Mora¹, Andrea Solera-Herrera², Mónica Salazar-Villanea², José Moncada-Jiménez². ¹National University, Heredia, Costa Rica. ²University of Costa Rica, San José, Costa Rica.
 Email: luissol2002@gmail.com
 (No relevant relationships reported)

The hormone insulin-like growth factor-1 (IGF-1) has anabolic effects in adults. The aging process negatively affects IGF-1 levels, muscle strength, physical performance, and cognitions. There is limited evidence regarding the effects of resistance training (RT) exercise on IGF-1 levels, muscle strength, physical function, and cognitions in Latin American female older adults. **PURPOSE:** To determine the effect of a RT program on IGF-1, muscle strength, physical function and cognitions in Costa Rican female older adults. **METHODS:** Twenty-six older adults were randomly assigned to a control (CTRL, n = 14, age = 68.8 \pm 3.7 yr.) or experimental (EXP, n = 12, age = 69.3 \pm 2.5 yr.) group. Both groups attended the exercise sessions two times/week, 40-min/session, for 8 weeks. The CTRL group performed slow-motion stretching exercises, and the EXP group performed RT exercises at 70% of 8-RM. Pre- to post-measurements were obtained on IGF-1, muscle strength, the 30-s chair-rise test, and short-term memory, working memory, psychomotor speed, attention and mental flexibility. Mean differences were studied by mixed 2 (groups) x 2 (measurements) ANOVA. Tukey's post-hoc tests followed significant ANOVA interactions. **RESULTS:** IGF-1 increased in EXP (Pre= 161.0 \pm 55.6 vs. Post= 205.3 \pm 49.3 ng/mL) and CTRL (Pre= 128.6 \pm 51.5 vs. Post = 174.9 \pm 70.7 ng/mL) groups (p < 0.05). Significant improvements (p < 0.05 for all) were found in leg extension (EXP= 52.3 \pm 9.4 vs. CTRL= 47.9 \pm 8.6 kg), chest press (EXP= 52.3 \pm 16.1 vs. CTRL= 42.6 \pm 9.1 kg), hip adduction (EXP= 47.1 \pm 12.8 vs. CTRL= 37.8 \pm 6.7 kg), back strength (EXP= 45.5 \pm 10.4 vs. CTRL= 39.4 \pm 4.6 kg), 30-s chair test performance (EXP= 14.8 \pm 1.3 vs. CTRL= 10.3 \pm 1.8 rep/30-s), and mental flexibility (EXP= 143.0 \pm 16.6 vs. CTRL= 142.1 \pm 16.4 s). **CONCLUSION:** A RT program improved muscle strength, physical function, and mental flexibility in female older adults compared to an active control group. The positive change in mental flexibility is a relevant finding due to the small number of studies in older adults. The increase in IGF-1 in both groups following eight weeks of physical activity and training are beneficial for older adults due to the proven importance of growth factors for brain health.

2101 Board #20 May 28 2:00 PM - 3:30 PM
Functional Characteristics Of Musculoskeletal Ambulation Disability Symptom Complex (mads) In Community-dwelling Older Women

Yasuo KIMURA¹, Mamoru HISATOMI¹, Toshinobu IKEGAMI², Kazuko OHKI¹, Masamichi MACHIDA³, Mieko SHIMADA⁴, Nobuko HONGU, FACSM⁵. ¹Inst. Fitness & Health Sciences, Toshima, Tokyo, Japan. ²Saga University, Saga-city, Japan. ³Saga University, Saga, Japan. ⁴Chiba Prefectural University of Health Sciences, Chiba, Japan. ⁵The University of Arizona, Tucson, AZ. (Sponsor: Nobuko Kay Hongu, FACSM)
 Email: kimyaz4162@yahoo.co.jp
 (No relevant relationships reported)

PURPOSE: For promoting the independence and prevention of falls of older adults, new category of motor disorders was established: musculoskeletal ambulation disability symptom complex (MADS). MADS is defined as an increased risk of falls and isolation due to an age-related decline in balance and walking ability. The purpose of this study was to understand functional characteristics of MADS by examining the association among physical performance, cognitive functions and sedentary behavior in older community-dwellers in Japan.

METHODS: Participants: 59 women aged 65 years and older (mean age 71 \pm 4 yrs.) participated in this study. After the participants completed a demographic questionnaire, motor function assessments measurements, one-leg standing time with eyes open (OLS) and timed up-and-go test (TUG), were conducted as diagnostic criteria for MADS. Then, the participants were divided into two groups according to OLS time; **G1:** longer than 15 sec. and **G2:** less than 15 sec. **Measurements:** Following variables were measured; 1) physical function -- hand-grip strength, chair-stand, functional reach, gait speed (10 m), 2) cognitive function -- Mini-Mental State

Examination (MMSE) and Trail Making Test-A (TMT-A), and 3) sedentary behavior -- self-reported questionnaire. Data are presented as means \pm SD, and analyzed using unpaired t-test and ANCOVA.

RESULTS: The average time of OLS was significantly different between G1 and G2 groups (61.3 \pm 36.9 and 8.2 \pm 3.6 sec., p<0.01). Age was significantly different between the G1 and G2 (70.3 \pm 2.5 vs. 72.7 \pm 3.2 yrs., p<0.05). The results show that maximal gait speed and TUG were significantly lower in G1 than G2 (1.82 \pm 0.24 vs. 1.66 \pm 0.25 m/sec., p<0.01) and (7.0 \pm 1.1 vs. 8.0 \pm 1.5 sec., p<0.05), respectively. In ANCOVA adjusting for the age, TMT-A and sedentary time were significantly different between G1 and G2; TMT-A : 93.9 \pm 29.8 sec. vs. 103.3 \pm 30.6 sec., p<0.01 and sedentary time: 8.8 \pm 0.9 vs. 10.2 \pm 1.5 hrs./day, p<0.05. MADS may affect the TMT-A and sedentary time in the older women.

CONCLUSIONS: These results suggest that decline in physical and cognitive functions, and sedentary behavior may be significantly associated with the risk of MADS in older women. Follow up studies are necessary to examine physical and cognitive functions of older adults with and without MADS.

 (No relevant relationships reported)

The aging process is associated with physiological changes that cause progressive declines in biological function, imposing a potential threat to the functional capacity. This condition impairs elderly independence, primarily when it is associated with chronic diseases or locomotive disorders. On the other hand, the physical exercise can mitigate some of those effects **PURPOSE:** the study aimed to analyze the effects of three different training programs (strength, muscular endurance, and aerobic) on functional autonomy, quality of life, and elderly physical fitness index. **METHODS:** After the inclusion and exclusion criteria, the sample consisted of 133 individuals, randomly divided into four groups: muscle strength group (MSG=31) muscular endurance group (MEG=32) aerobic group (AG=35) and a control group (CG=35). Initially, the sample groups were submitted to the following procedures: functional autonomy (GDELAN protocol), quality of life (WHOQOL-OLD), and elderly physical fitness index (1600m walking test, left leg calf circumference and lean mass for body composition assessment, elbow flexion, and extension test, sit and stand-up test, range of motion evaluation through the Normalflex). **RESULTS:** After four months of training, there was a significant difference (p<0.0001) between the CG and all other experimental groups for functional autonomy. For quality of life, there was a significant difference in the post-test phase between the CG and the experimental groups in the domain 1 (AG: p=0.001; MSG: p<0.0001; MEG: p=0.001) and domain 6 (MSG: p=0.011), the results being favorable to those three groups. In the pretest phase, there was no significant difference between the groups. For the elderly physical fitness index there was a significant difference in the post-test phase between the CG and the experimental groups, in the VO2max (AG: p<0.0001 and MEG: p<0.0001), range of motion (AG: p<0.0001; MSG: p<0.0001; MEG: p<0.0001) and muscle endurance (AG: p=0.025), the results being favorable for those three groups. In the pretest, there was no significant difference between the groups. **CONCLUSIONS:** The strength group presented a higher rate of functional autonomy improvement ($\Delta\%$ -22.5876, p<0.0001), quality of life ($\Delta\%$ 11.96531, p<0.0001) and elderly physical fitness index ($\Delta\%$ 11.0992, p<0.0001).

EKG CHARACTERISTICS IN SENIORS PARTICIPATING IN A STRUCTURED FITNESS PROGRAM: A PILOT STUDY

Taylor Garcia, Gretchen Cagle, Eric Vinke, James Jones, Anthony Ferdinand, Joshua Jarrell, Christopher Babtiste, Lauren Adlof, Amy A. Crawley, Ludmila Cosio Lima, FACSM. University of West Florida, Pensacola, FL. (Sponsor: Ludmila Cosio Lima, FACSM)
 Email: lcosiolima@uwf.edu
 (No relevant relationships reported)

PURPOSE: Undergraduate exercise science students can benefit from curriculum which includes authentic, hands-on opportunities for learning. A 12-lead

electrocardiograph (ECG) can serve as both as a teaching and screening tool to assess cardiac abnormalities in seniors (over age 65) prior to beginning an exercise program. The purpose of this pilot study was to evaluate the ECG characteristics of older adults prior to participation in a twice-weekly supervised strength training program. **METHODS:** Thirty seniors (Males = 10; Females = 20; Age = 72 ± 7.6yrs) completed cardiovascular screening with resting 12-lead ECG analysis prior to program participation. An exercise physiologist reviewed all ECG results and any identified abnormalities were referred to a cardiologist. Gender, ECG abnormalities, and anthropometrics were compared using a mixed model ANOVA. Chi-square analysis was used to test for differences in the frequency of ECG findings across gender. **RESULTS:** Thirty seniors (Males = 10; Females = 20; Age = 72 ± 7.6yrs) completed cardiovascular screening with resting 12-lead ECG analysis prior to program participation. An exercise physiologist reviewed all ECG results and any identified abnormalities were referred to a cardiologist. Gender, ECG abnormalities, and anthropometrics were compared using a mixed model ANOVA. Chi-square analysis was used to test for differences in the frequency of ECG findings across gender. **CONCLUSIONS:** A pre-exercise ECG can be a useful teaching and screening tool for students who are preparing to supervise older adults in a structured strength training program. ECG results can be used to adjust training variables (type, duration, and intensity) accordingly for each individual senior participant.

 Chatting While Cycling Can Enhance "Positive Affect" In Patients With Cardiovascular Disease**

YUSUKE ITAYA¹, Shinji Sato², Shingo Otsuki³. ¹Nozaki Tokushukai Hospital, Osaka, Japan. ²Teikyo Heisei University, Tokyo, Japan. ³Osaka Sangyo University, Osaka, Japan.
 Email: itaya515@outlook.com
 (No relevant relationships reported)

PURPOSE: Previous studies demonstrated that aerobic exercise activates the frontal area of the left hemisphere, which stimulates optimistic feelings. We hypothesized that having fun chatting with friends while cycling (Chatting While Cycling: CWC) would enhance the benefits of exercise, and this would particularly benefit patients with cardiovascular diseases who find exercising a strenuous activity. Therefore, the aim of present study was to analyze the differences in the positive affect of patients during two aerobics routines: CWC and cycling alone.

METHODS: The sample comprised eight patients with cardiovascular disease and nine healthy gender-matched volunteers that performed two aerobics routines. To determine the positive affect, we performed electroencephalography (EEG; NegPos, Neuro Sky) and applied the following formula (Right Alpha 10 sec Avg - Left Alpha 10 sec Avg) / (Right Alpha 10 sec Avg + Left Alpha 10 sec Avg). In addition, the subjective optimistic feelings during exercise was measured using a questionnaire. Each routine involved the same exercises and duration (15 minutes). The intensity was controlled through a 60% peak VO₂ in the cardiopulmonary exercise test. The mean values of EEG data were calculated and used for analysis in the paired t test (level of significance, *p* < .05). The relationship between positive affect and subjective optimistic feelings was analyzed using Pearson's coefficient of correlation.

RESULTS: In patients with cardiovascular disease, the positive affect during exercise was significantly higher for CWC than cycling alone (CWC 46.9 vs. cycling alone -5.9, *p* = 0.014). On the other hand, healthy volunteers exhibited no such routine-dependent differences. Furthermore, positive affect was associated with increased subjective optimistic feelings during CWC (*r* = 0.839, *p* = 0.005).

CONCLUSIONS: Aerobic exercise while chatting with friends is recommended for positive affect in cardiac rehabilitation settings. The authors have no conflicts of interest.

 Technological Advancements Fail To Elicit Improvements In CVD Detection**

Nick J. Rein, Emily A. Freund, Courtney D. Jensen, Cynthia Villalobos, J. Mark VanNess. *University of the Pacific, Stockton, CA.*
 (No relevant relationships reported)

Modern and more sophisticated body composition instruments may offer superior determination of cardiovascular risk compared to older, more simple assessments such as body mass index (BMI). **PURPOSE:** To determine whether the Fit3D-calculated measurement of "Body Shape Rating" (BSR) is more accurate than BMI

as a predictor of cardiovascular risk factors. **METHODS:** 17 subjects (7 female, 10 male; aged 18-26) underwent laboratory testing beginning with a body composition assessment by the Fit3D (FIT3D Inc., San Mateo, CA). Subjects then had their heart rate and blood pressure recorded in a resting state before, during, and after a treadmill exercise bout. Descriptive statistics characterized the study sample and simple linear regressions tested the relationships between BSR and blood pressure. **RESULTS:** In the pre-exercise measurements, BSR correlative measures with systolic blood pressure, diastolic blood pressure, and mean arterial pressure were: *r* = -0.082 (*P* = 0.755), *r* = -0.052 (*P* = 0.843), and *r* = -0.102 (*P* = 0.698) respectively. In the post measures, BSR correlative values with systolic blood pressure, diastolic blood pressure, and mean arterial pressure were: *r* = -0.128 (*P* = 0.625), *r* = -0.073 (*P* = 0.782), *r* = -0.102 (*P* = 0.698) respectively. **CONCLUSION:** In our sample, BSR failed to elicit significant correlations with blood pressure. While the Fit3D offers a clear technological improvement to simple anthropometric measurements, the pre- and post-exercise measurements did not indicate utility in determining cardiovascular risk.

 Walking Characteristics In Individuals With Stroke Differ Based On Walking Speed, Endurance And Daily Steps**

Reed Handlery¹, George Fulk², Christine Pellegrini¹, Jill Stewart¹, Courtney Monroe¹, Stacy Fritz¹. ¹University of South Carolina, Columbia, SC. ²SUNY Upstate Medical University, Syracuse, NY.
 Email: handlery@email.sc.edu
 (No relevant relationships reported)

PURPOSE: Walking is an ideal means of obtaining physical activity, yet people with stroke take few daily steps. The purpose of this study was to examine how the walking characteristics of bouts per day, maximum steps per bout and time spent walking differ between individuals with various walking speeds, walking endurance and daily steps. Additionally, we aimed to identify cutoff values for differentiating active and inactive ambulators (i.e. those who do and do not achieve physical activity guidelines through walking).

METHODS: Stepping data from 252 individuals with chronic stroke (>6 months) with mean age of 63 (13) years and step count of 4,277 (3,064) steps per day were analyzed. Individuals were placed into previously established levels of ambulation (i.e. household ambulators, limited community and unlimited community ambulators), based on walking speed, walking endurance and daily steps (via two days of StepWatch activity monitoring). Differences in walking characteristics were assessed between ambulation levels (e.g. household vs. community ambulators). Linear regression determined which characteristics best predicted daily step counts. Receiver Operating Characteristic (ROC) curves and area under the curve (AUC) determined which variable was most accurate in classifying active (>5,500 steps) and inactive (<5,500 steps) individuals.

RESULTS: Regardless of categorization by walking speed, walking endurance or daily steps, household ambulators had significantly fewer bouts per day, maximum steps per bout and time spent walking compared to both limited and unlimited community ambulators (*p* < 0.001). Only 81 (32%) participants obtained >5,500 steps per day. The two highest AUC values were 0.91 (95% CI 0.88, 0.95) for maximum steps per bout and 0.83 (95% CI 0.78, 0.88) for bouts per day. Cutoff values of 648 maximum steps per bout or 53 bouts were used to differentiate active and inactive ambulators.

CONCLUSIONS: Walking characteristics differed based on an individual's walking speed, walking endurance and daily steps. Differences in daily steps between household and community ambulators are largely due to shorter and fewer walking bouts. Interventions aimed at improving walking after stroke should promote increased walking bouts of any length to increase physical activity after stroke.

 Gross Motor Functions Assessed Through The Tgmd-3 In Down Syndrome Individuals And Related Gender Differences**

Paola Sbriccoli, Valentina Camomilla, Giuseppe Vannozzi, Maria Francesca Piacentini, Amy Wynn, Cecilia Bratta, Federico Quinzi. *University of Rome Foro Italico, Rome, Italy.*
 Email: paola.sbriccoli@uniroma4.it
 (No relevant relationships reported)

PURPOSE: Down Syndrome (DS) individuals show a markedly reduced general coordination, resulting in an overall reduced motor proficiency which limits their participation and, consequently, inclusion in sport activities. In this work we aim to characterize gross motor functions in DS, assessed by means of the Test of Gross Motor Development (TGMD 3), and assess possible gender-related differences.

METHODS: Thirty-six age- and gender-matched DS individuals (Age: 29.1±7.5 years; Stature: 1.53±0.09 m; Mass: 67±14 kg; BMI: 28.6±14.1 kg/m²; *n* = 18 females (FE), 18 males (MA)), recruited in 5 European countries, performed the TGMD

version 3 (TGMD-3). Participants were matched also for their daily physical activity ($p = 0.6$) as assessed by the international physical activity questionnaire (IPAQ). TGMD-3 includes 13 skills classified as Locomotor Skills (Running, Galloping, Hopping, Skipping, Horizontal jumping, and Sliding) or Ballistic Skills (Two-hand and One-hand striking, Dribbling, Overhand throwing, Underhand throwing, Catching, and Kicking). For each skill, two attempts were performed. A video analysis was performed to assess if the performance criteria were respected. For each criterion, the participant scored 1 if the performance criterion was respected and 0 if not. Individual scores of the two attempts for each skill classified as Locomotor or Ballistic were separately summed. The total gross motor functions score was the sum of Locomotor and Ballistic skills. All scores were computed as a percentage of the maximum achievable score. MA and FE scores were compared using RM-ANOVAs ($\alpha=0.05$). **RESULTS.** The participants had a total gross motor function score of 51% on average, similar for MA and FE ($F_{1,34} = 1.39$; $p = 0.24$; $M = 54\%$; $F = 48\%$). No significant differences between MA and FE were observed for the total scores of Locomotor or Ballistic skills ($F_{1,34} = 1.45$; $p = 0.23$). At single skill level, MA outperformed FE in the kicking skill ($F_{1,34} = 8.14$; $p = 0.007$; $M = 47\%$; $F = 22\%$). **CONCLUSION.** These results highlight gross motor functions limitations in this population, showing a similar impairment of MA and FE, especially for locomotor functions. The different score obtained between MA and FE in the kicking skill may reflect an European cultural bias. Co-funded by the Erasmus + Programme of the European Union, GA 2018-2512.

Using Causal Agency Theory To Promote Functional And Independent Performance In Adults With Intellectual Disabilities

Iva Obrusnikova, Richard R. Suminski, Albert R. Cavalier, Ashleigh E. Blair, Cora J. Firkin. *University of Delaware, Newark, DE.*
 Email: obrusnik@udel.edu
 (No relevant relationships reported)

Research suggests adults with intellectual disabilities (ID) have significantly lower levels of physical activity (PA) and fitness compared to the general population. This can affect their physical functioning and increase risk for obesity. Carefully structured exercise has improved functional performance in adults with ID. Limited exercise interventions for adults with ID emphasize self-determined behaviors, which can facilitate PA and ultimately quality of life among adults with ID. Causal Agency Theory (CAT) explains how people become self-determined; that is how they develop the actions and beliefs necessary to engage in self-caused, autonomous action in response to basic psychological needs and autonomous motivation as well as contextual and environmental challenges. **PURPOSE:** To examine the effects of a 10-week guided progressive resistance training (PRT) program on functional and independent performance in adults with ID. **METHODS:** Using a block randomization, 11 participants (25±6yrs) were allocated to a guided group (GG) and 11 (23±8yrs) to a non-guided group (NGG). GG received a PRT intervention in a community-based fitness center that included 3-week familiarization to promote correct and independent performance of exercises and technology-enhanced strategies to promote CAT skills (e.g., goal setting, choice-making). NGG only received the PRT intervention with instruction typically provided by a certified personal trainer. **RESULTS:** Paired *t* tests showed that after the 10-week PRT program, only the GG significantly improved ($p < .05$) correct and independent performance of 4 PRT exercises and scores on Six-Minute Walk Test (SMWT) and Plank Test compared to the NGG. Both groups significantly improved ($p < .05$) Chest Press 1RM and Leg Press 1RM. After controlling for preintervention differences, ANCOVA found practically and/or statistically significant differences between GG and NGG for postintervention Chest Press 1RM, $F(1, 20) = 3.00$, $p = .100$, $\eta_p^2 = .14$; Leg Press 1RM, $F(1, 20) = 7.25$, $p = .015$, $\eta_p^2 = .29$; SMWT, $F(1, 20) = 10.85$, $p = .000$, $\eta_p^2 = .38$; and Plank Test, $F(1, 20) = 3.49$, $p = .078$, $\eta_p^2 = .16$. **CONCLUSION:** The guided PRT intervention with its familiarization training and technology-enhanced CAT strategies has the potential to promote functional and independent performance in adults with ID.

Which Exercises Close Diastasis Recti Abdominis In Parous Women? An Experimental Cross-sectional Study

Sandra Gluppe¹, Marie E. Engh², Kari Bo¹. ¹Norwegian School of Sport Sciences, Oslo, Norway; ²Akershus University Hospital, Lørenskog, Norway.
 Email: s.l.gluppe@nih.no
 (No relevant relationships reported)

Diastasis recti abdominis (DRA) is defined as an impairment with midline separation of the two rectus abdominis muscles along the linea alba. The condition affects a significant number of women during the antenatal- and postnatal period and is hypothesized to cause abdominal-, pelvic-, and low back pain, decreased abdominal muscle strength, as well as cosmetic concerns. A study among US physical therapists

found that the most commonly used exercises in treatment of DRA were indrawing and pelvic floor muscles (PFM) exercises. However, experimental studies have found that both indrawing and PFM contraction increase the inter-recti distance (IRD). Randomized controlled trials (RCT) are few, and both interventions and results differ between studies. **PURPOSE:** To investigate the immediate effect of different abdominal- and PFM exercises on IRD in women with DRA. **METHODS:** Following power calculation of sample size, 38 parous women were included in this cross-sectional study. 2D ultrasound was used to measure IRD at rest and in random order of eight different exercises. A paired *t*-test was used to compare IRD at rest with IRD recorded during each of the exercises and differences between exercises. Means with 95% confidence intervals (CI) are reported. *P*-value was set to <0.05 . **RESULTS:** Head lift and twisted crunch significantly decreased the IRD, both above and below the umbilicus. Above the umbilicus, the mean difference between rest and head lift was 10 mm (95% CI: 7, 13.2, $p < .001$) and twisted crunch 9.4 mm (95% CI: 6.3, 12.5, $p < .001$). Below the umbilicus, the mean difference between rest and head lift was 6.1 mm (95% CI: 3.2, 8.9, $p < .001$) and twisted crunch 3.5 mm (95% CI: 0.5, 6.4, $p = .02$). PFM contraction, maximal in-drawing and PFM contraction+maximal in-drawing increased the IRD below the umbilicus, mean difference; -2.8 mm (95% CI: -5.2, 0.5, $p = .02$), -4.7 mm (95% CI: -7.2, -2.1, $p < .001$) and -5.0 mm (95% CI: -7.9, -2.1, $p < .001$), respectively. **CONCLUSION:** Head lift and twisted crunch decrease, while maximal in-drawing and PFM contraction increase the IRD. RCTs are needed to investigate whether head lift and twisted crunch are effective in permanently narrowing the IRD. The Norwegian Women's Public Health Association fully funded the study.

Critical Ages For Changes In Isometric Force Production In Women Aged 20 To 89 Years

Ryan M. Miller, Aaron D. Heishman, Eduardo D.S. Freitas, Samuel R. Buchanan, Japneet Kaur, Brady S. Brown, Keldon M. Peak, Jennifer N. Norman, Kelly E. Joniak, J. Mikhail Kellawan, Hugo M. Pereira, Debra A. Bembem, FACSM, Michael G. Bembem, FACSM. *University of Oklahoma - Department of Health & Exercise Science, Norman, OK.* (Sponsor: Michael G. Bembem, FACSM)
 (No relevant relationships reported)

Although one of the greatest changes observed with aging is the loss of muscular strength, few studies have identified the onset of these reductions in women with increasing age. **Purpose:** To examine the influence of chronological age on maximal voluntary isometric contraction (MVIC) force for the finger flexors and knee extensors (KE) in recreationally active women. **Methods:** One-hundred and forty-two women (age: 47.1 ± 17.7 years, height: 164.2 ± 7.0 cm, 67.1 ± 10.7 kg), matched for physical activity were included in the present analysis. Participants were selectively recruited to include ≥ 10 participants for each five-year age interval (e.g. 20-24, 25-29 years, etc.). Testing included three separate visits where participants completed three trials of maximal handgrip strength tests (HGS) followed by three trials of KEMVICs performed on the right side of the body. Participants completed each trial within the same hour of day as the initial testing session and all testing visits were completed 7-10 days apart. Segmental analyses were performed in combination with the Davies test to verify critical age periods for mean MVIC values. An age was deemed 'critical' when statistical significance was achieved performing the Davies test *a priori* at $p \leq 0.05$. **Results:** Mean \pm SD for KEMVIC and HGS were 209.2 ± 43.6 Nm and 31.6 ± 4.3 kg, respectively, and model fit for the KEMVIC and HGS across the participants was $r^2: 0.64$ and $r^2: 0.67$ ($p < 0.001$), respectively. The Davies test revealed critical age periods for KEMVIC and HGS of 46.1 ± 3.6 and 66.28 ± 1.29 years, respectively. Both muscle groups displayed marginal losses prior to the respective critical age periods (KEMVIC: -0.45 Nm/year and HGS: -0.03 kg/year), whereas following the critical age period, the reductions increased significantly for both muscle groups (KEMVIC: 2.32 Nm/year, $p < 0.001$; HGS: -0.67 kg/year, $p = 0.03$). Importantly, the segmented model provided a significantly improved fit when compared to linear and quadratic models for KEMVIC ($p < 0.001$ and $p < 0.001$, respectively) and HGS ($p < 0.001$ and $p = 0.027$, respectively). **Conclusion:** These data indicate that muscle groups of the upper and lower body do not display uniform changes with increased age. Although both muscle groups are routinely needed in daily life, the upper body appears to maintain strength until later in life.

2111 Board #30 May 28 2:00 PM - 3:30 PM
Increasing Exercise Is Not Associated With An Increase In Sedentary Time In Obese Adults

Azalea May Walc, Simrat Soni, Robert Ross, FACSM. *Queen's University, Kingston, ON, Canada.*
 Email: 15amw1@queensu.ca
 (No relevant relationships reported)

BACKGROUND: It is now established that sedentary time is an independent predictor of morbidity and mortality. Whether increasing exercise is associated with an increase in objectively measured sedentary time is unclear.

PURPOSE: To determine if increasing exercise consistent with consensus recommendations is associated with corresponding increases in sedentary time in abdominally obese adults. **METHODS:** Participants were 98 sedentary adults (BMI 31.8 ± 3.7 kg/m², age 55 ± 7.1 years) randomly assigned to one of the following 4 groups: i) no-exercise control (n=19), ii) low-amount, low-intensity exercise (LALI) (180 and 300 kcal/ session for women and men, respectively, at 50% of VO₂peak, n=24), iii) high-amount, low-intensity exercise (HALI) (360 and 600 kcal/session, respectively, at 50% of VO₂peak, n=36), iv) high-amount, high-intensity exercise (HAHI) (360 and 600 kcal/session, respectively, at 75% of VO₂peak, n=24). All exercise sessions were supervised. Sedentary time was determined objectively by accelerometry measured at baseline, 8, 16 and 24 weeks using established cut-points. **RESULTS:** The mean exercise time for LALI, HALI and HAHl were 31.2 ± 6.7 , 58.3 ± 7.8 and 42.7 ± 4.5 min/day respectively. Corresponding values for sedentary time were 10.6, 10.3, and 10.4 hrs/day respectively. No statistically significant differences in sedentary time at baseline was observed between exercise groups ($p=0.81$). Similarly, no significant difference in the change in sedentary time at 24 weeks was observed between exercise groups ($p=.59$). The mean value for change in sedentary time for the 3 exercise groups combined was -15 mins/day. **CONCLUSIONS:** Increasing exercise consistent with consensus recommendations is not associated with a corresponding change in sedentary time independent of exercise amount or intensity. These observations counter the suggestion that fatigue associated with the adoption of exercise in obese adults may lead to corresponding increase in sedentary time.

2112 Board #31 May 28 2:00 PM - 3:30 PM
VO₂-PO Discordance In Paraplegia; Considerations For Using Power Output To Prescribe Exercise At Various Intensities

David W. McMillan¹, Jennifer L. Maher², James LJ Bilzon², Kevin A. Jacobs, FACSM³, Mark S. Nash, FACSM¹. ¹Miami Project to Cure Paralysis, Miami, FL. ²University of Bath, Bath, United Kingdom. ³University of Miami, Miami, FL. (Sponsor: Kevin A Jacobs, FACSM)
 Email: dmcmillan@med.miami.edu
 (No relevant relationships reported)

Endurance exercise is often prescribed relative to peak power output (% PO_{peak}) obtained during a graded exercise test (GXT). Persons with spinal cord injury (SCI) conducting arm cycle ergometry (ACE) display a unique VO₂-PO relationship not yet quantified in the context of exercise prescription. Indirect evidence suggests that a relatively low % PO_{peak} will be required to elicit a given % VO₂ during moderate intensity continuous exercise (MICE). Applying this concept of VO₂-PO discordance to high intensity interval exercise (HIIE) prescription, one must consider the possibility for a seemingly moderate intensity % PO_{peak} to elicit a physiological response indicative of HIIE.

PURPOSE: To determine the % PO_{peak} required to elicit a target VO₂ during MICE, and to explore the use of % PO_{peak} to prescribe HIIE in persons with SCI.

METHODS: Ten adult men (39±10 yr) with chronic (13.2±8.8 yr) paraplegia (T2-T10) completed a GXT with 3 min stages where PO increased 20 W-stage⁻¹ from a starting PO (10-40 W) estimated to elicit volitional exhaustion in 8-12 min. Then, in a randomized order, % PO_{peak} was used to prescribe MICE and HIIE. The duration of each session was chosen so that the sessions were isocaloric. During MICE, ΔVO₂/ΔPO was used to estimate the power output that would elicit a steady state 50% VO₂peak. HIIE was completed with 2 min duty cycles at 70:10% PO_{peak}. For HIIE, the last minute of the work or recovery phase was used to calculate the mean VO₂ of working and recovery phases.

RESULTS: Mean cardiorespiratory fitness (19.2±5.2 ml·kg⁻¹·min⁻¹) classified participants as 'good' based on normative data. PO_{peak} was a strong predictor of VO₂peak ($r=.960$, $p<.001$) and VO₂ gain (ΔVO₂/ΔPO) was 10.3 ± 1.8 ml·min⁻¹·W⁻¹. During MICE, 24.6±6.7% PO_{peak} elicited a VO₂ of $53.1 \pm 6.5\%$ VO₂peak (10.1±2.2 ml·kg⁻¹·min⁻¹). During HIIE, the work and recovery phases averaged 88.3 ± 6.7 and $49.2 \pm 6.8\%$ VO₂peak (16.9±4.2 and 9.3±2.2 ml·kg⁻¹·min⁻¹, respectively), and 29.4±7.7% of the session was spent above 80% VO₂peak. MICE and HIIE were isocaloric (115.9±21.8 and 116.6±35.0 kcal, respectively; $p=.903$).

CONCLUSION: Both MICE and HIIE conditions demonstrated evidence of VO₂-PO discordance. These findings emphasize the unique considerations pertaining to the use of % PO_{peak} to prescribe ACE in SCI.

Avoiding Diabetes After Pregnancy Trial In Moms (ADAPT- M): Evaluating Fitness In Postpartum Women Who Have Had Recent Gestational Diabetes Mellitus (GDM)

Faith Delos-Reyes, Mireille Landry, Jennifer Price, Wei Wu, Geetha Mukerji, Sarah McTavish, Paula Harvey, Lorraine Lipscombe. Women's College Hospital, Toronto, ON, Canada.
 Email: faith.delos-reyes@wchospital.ca
 (No relevant relationships reported)

Gestational diabetes mellitus (GDM) affects approximately 6% of women, and 20% develop type 2 diabetes (T2DM) by 10 years post delivery with higher rates in non-Caucasian ethnic groups. Early postpartum lifestyle interventions such as physical activity (PA) are recommended to improve health outcomes and reduce future T2DM. Despite benefits of PA, postpartum women report difficulty to engage and adhere to PA due to barriers such as childcare and poor support. Little is known about whether this high-risk group are achieving age-predicted fitness (APF) and meeting PA guidelines.

PURPOSE: To describe cardiorespiratory fitness and PA levels in Caucasian and non-Caucasian women with recent GDM, and the association between fitness and PA measures. **METHODS:** This cross-sectional study recorded baseline data from a multi-ethnic cohort of women with recent GDM at 12 to 20 weeks postpartum, who were part of a health-coaching intervention called Avoiding Diabetes after Pregnancy Trial in Moms (ADAPT-M) between 2014 and 2017. Women underwent a graded exercise treadmill test, anthropometric measures, diastasis rectus screening and completed the International Physical Activity Questionnaire (IPAQ). Baseline characteristics were compared between Caucasian and non-Caucasian ethnicity using T-test, Chi square and Mann-Whitney U tests. The relationship between APF and PA guidelines was assessed with a Chi-Square test. **RESULTS:** We evaluated 149 participants at mean 16.5 ± 4.3 weeks postpartum (mean age 36.7 ± 4.6 years, 70.5% non-Caucasian), had a mean fitness of 9.7 ± 1.9 metabolic equivalents ($98 \pm 19.2\%$ APF), body fat $36.2 \pm 5.6\%$, BMI 29.7 ± 6.8 kg/m², and diastasis rectus was present in 20%. Of those, 52% were below APF while 84.5% were meeting PA guidelines (IPAQ). Non-Caucasian women were significantly less likely to meet PA guidelines ($p=0.0002$) and had lower PA levels ($p<0.001$). Overall, level of PA on the IPAQ did not correlate with APF ($p<0.10$). **CONCLUSION:** Postpartum women with recent GDM had average APF and 84.5% were meeting PA guidelines, although significantly lower levels were seen in non-Caucasian women. Level of PA on the IPAQ did not correlate with APF in this population. Postpartum diabetes prevention programs for women with recent GDM should optimize PA, particularly for higher-risk non-Caucasian ethnic groups.

Pregnancy In Elite Athletes And Their Return To Sport

Christine Sundgot-Borgen¹, Jorunn Sundgot-Borgen, FACSM¹, Grethe Myklebust¹, Nina Solvberg¹, Monica Klungland Torstveit². ¹Norwegian School of Sport Sciences, Oslo, Norway. ²University of Agder, Kristiansand, Norway.
 Email: c.s.borgen@nih.no
 (No relevant relationships reported)

PURPOSE: The study aimed to enhance knowledge on pregnancy and return to sport in the postpartum period in elite female athletes.

METHODS: 34 Norwegian elite athletes (33.1 year) and 34 active controls (31.5 year) were asked about training and competitive history, pregnancy-related issues, injuries, eating disorders (ED) and practical experiences, through a questionnaire and interview. Independent Samples T-tests or Chi-square Tests for between-group differences and paired-Samples T-tests and repeated measures ANOVA for within group differences were used.

RESULTS: No group differences in fertility problems, miscarriage, pre-term birth or low birth weight were found. Both groups decreased training volume all trimesters and the first two postpartum periods compared to pre-pregnancy. More athletes (71 %) than controls (32 %) ($p=.002$) returned to sport/exercise at week 0-6 postpartum. We found no group differences in complications during pregnancy and delivery, but athletes reported fewer common complaints such as nausea ($p<.01$), musculoskeletal complaints ($p<.05$) and obstipation ($p<.05$). Twelve percentage of the athletes experienced stress fracture postpartum. Number of athletes with clinical ED (12 %) was reduced postpartum (6 %), while constant in controls (3 %). Athletes were not satisfied with advice related to strength training (18 %) and nutrition (41 %) during pregnancy.

CONCLUSION: Elite athletes and active controls get pregnant easily, deliver healthy babies and decrease training during pregnancy and the first postpartum periods compared to pre-pregnancy. Most athletes and every third control returned to sport or exercise at week 0-6 postpartum. Athletes report limited nutrition guidance, stress fractures and decreased ED postpartum.

2115 Board #34 May 28 2:00 PM - 3:30 PM
Preferred Leg Drives Seated And Bilateral Exercise In Chronic Stroke And Healthy Control
 Jordan Brown¹, Nicholas Siekirk¹, Bradley Kendall², Victoria Pardo³, Qin Lai³, Sujay Galen⁴, Trevor McCready⁵, Samantha Atty⁶, Sam Wilson¹, Jessica Mutchler¹, Tamara Hew-Butler, FACSM³. ¹Georgia Southern University, Statesboro, GA. ²Taylor University, Upland, IN. ³Wayne State University, Detroit, MI. ⁴Georgia State University, Atlanta, GA. ⁵Central Michigan University, Mount Pleasant, MA. ⁶University of Southern California, Los Angeles, CA. (Sponsor: Tamara Hew-Butler DPM, PhD, FACSM, FACSM)
 Email: jb17162@georgiasouthern.edu
 (No relevant relationships reported)

PURPOSE: The NuStep Cross Trainer (NS) approximates the bipedal and upright stepping pattern. However, it is unknown how the history of stroke may influence recurrent exercise. The purpose of this study was to examine performance outcomes on the NS in a chronic stroke condition (SC) and an age plus sex-matched control (HC). **METHODS:** In order to determine cadence, each participant performed a 10 minute (min) pretest on the NS at an RPE between 12 and 16. After returning to resting HR and BP, participants then performed a 5-min exercise bout on the NS. **Summary of RESULTS:** SC and HC did not differ in age (*Mdn*: 66 years vs. 57 years, respectively) or BMI (Stroke: $M = 27.02 \pm 4.57$ vs. Healthy: $M = 26.46 \pm 4.63$), $p > .05$. There were no differences in RPE, METS, elevation gain (ft), estimated energy cost (k/cal), average (avg.) speed (mph), avg. steps per min, or avg. bilateral power (W) between the HC ($n = 19$) and SC ($n = 15$); $p > .05$. However, HC produced higher total steps ($M = 723.18$ steps \pm 137.64) compared to the SC ($M = 597.67$ steps \pm 116.90); $t(30) = 2.683$, $p = .012$. Total step distance (miles) for the HC (mean rank = 19.74) was also greater than the SC (mean rank = 11.77), $U = 62.0$, $z = -2.363$, $p = .018$. However, Δ avg. pedal power (W) between the HC's limbs (left-right) ($M = -2.00 \pm 3.528$) was not different than SC (affected-non-affected) ($M = -3.50 \pm 4.852$); $t(29) = .997$, $p = .32$. HC Δ ROM (in) (mean rank = 17.50) did not differ from SC (mean rank = 13.62), $U = 85.5$, $z = -1.214$, $p = .252$. The SC did not demonstrate strength deficits on their affected side; $p > .05$. Bilateral comparison revealed the SC's affected side contributed less pedal power ($18.08W \pm 9.61$) than the non-affected side (21.58 ± 10.34); $p = .030$. HC produced higher levels of force on their preferred right leg ($M = 48.68$ lbs \pm 10.05 lbs vs. $M = 44.42 \pm 9.78$); $p < .001$. No ROM difference was observed between limbs in HC or SC; $p > .05$. **CONCLUSION:** Healthy participants covered more distance by producing more steps (not Δ ROM) in the 5-minute exercise bout on the NS. The mechanical coupling of the NS seems to encourage equal ROM contribution, but the preferred leg will contribute higher avg. power in both SC (i.e., via non-affected) and the HC (i.e., via right leg). This study was supported by a grant from the National Institutes of Health, P30 AG015281. And the Michigan Center for Urban African American Aging Research.

Patient-provider Discussions And Postpartum Health Outcomes
 Rebecca A. Schlaff, FACSM, Meghan Baruth. Saginaw Valley State University, University Center, MI.
 Email: raschlaff@svsu.edu
 (No relevant relationships reported)

Evidence suggests women value health-related conversations with health care providers, particularly during and after pregnancy. Patient-provider discussions about postpartum mental/physical changes during postpartum care may prepare women to cope with and view postpartum changes more favorably and engage in healthier behaviors after delivery. **PURPOSE:** To examine relationships between patient-provider discussion occurrence and satisfaction and 1) moderate-to-vigorous physical activity (MVPA), 2) body satisfaction, and 3) depressive symptoms postpartum. **METHODS:** Survey data were collected from 230 postpartum women (3-12 months) who received pre/postnatal care in the United States for a singleton pregnancy. Women reported occurrence of (yes/no) and satisfaction with (5-point Likert scale; 1=very dissatisfied, 5=very satisfied) patient-provider discussions about expected postpartum mental and physical health changes, current MVPA, body satisfaction (Body Areas Satisfaction Scale) and depressive symptoms (10-item Center for Epidemiologic Studies Depression Scale). Linear and logistic regression models examined relationships between postpartum patient-provider discussions (occurrence and satisfaction) and current MVPA (any vs. none; meeting recs vs. not meeting recs), body satisfaction, and depressive symptoms. **RESULTS:** Women were 7.2 \pm 2.8 months postpartum at the time of survey completion. Postpartum patient-provider discussions were reported in 73.4% of women. Satisfaction with information provided during postpartum discussions averaged 4.0 \pm 0.8. Overall, 74.3% engaged in any MVPA and 47.4% met recommendations. Women who reported a postpartum discussion were more likely to engage in any MVPA (OR=2.00, 95% CI: 1.06, 3.81). Higher body satisfaction was observed in women reporting postpartum discussions ($p=0.04$)

and greater discussion satisfaction ($p=0.002$). Depressive symptoms were inversely related to discussion satisfaction during postpartum care ($p=0.02$). **CONCLUSION:** Postpartum discussions with healthcare providers may not only benefit physical health, but also mental health and health behavior. Understanding the content of such discussions may help provide insight into what types of discussions can most effectively promote all aspects of postpartum health.

Postpartum Body Composition: A Case Study Of Two Pregnancies
 Jacilyn M. Olson, Larissa Boyd, Melissa Powers. University of Central Oklahoma, Edmond, OK.
 Email: jolson3@uco.edu
 (No relevant relationships reported)

Numerous changes to body composition occur during and post-pregnancy in apparently healthy women. Significant changes, specifically to fat mass and bone mineral density, have acute and chronic impacts on overall wellness. **PURPOSE:** The purpose of this case study is to examine the body composition changes of a woman in her 30s over two pregnancies. **METHODS:** Dual-energy x-ray absorptiometry (DEXA) scans were performed before each pregnancy and two weeks, five months, and twelve months after delivery. At each scan the participant was asked about physical activity, lactation status, and supplementation. **RESULTS:** DEXA scan results prior to pregnancy 1 (P1) and pregnancy 2 (P2) were similar for all variables, except total bone mineral density. However, the individual gained considerably more fat during P2 (P1: 15.7 lbs; P2: 28.7 lbs fat gained). Five months post-pregnancy, fat mass was still elevated (P1: 3.8 lbs; P2: 12.7 lbs over baseline) and continued to decrease until 12 months after delivery. Lean mass was increased from baseline at two weeks post-pregnancy (P1: 96.52 lbs.; P2: 97.1 lbs). However, gained lean mass was lost by five months postpartum (P1: 89.89 lbs.; P2: 91.2 lbs). During P1, lean mass remained about the same from five to 12 months but increased at 12 months after P2 (96.2 lbs). After P1, the individual had a substantial decrease in bone mineral density, losing 0.49% at two weeks postpartum, 4.68% at five months, and 9.20% twelve months. Bone mineral density remained below baseline prior to P2, but did not decrease as dramatically following P2. Using the initial baseline, bone mineral density was 3.53% lower at two weeks, 6.57% at five months, and 7.64% at 12 months. During both postpartums, the trunk (P1: 12.1%; P2: 11.54%), spine (P1: 13.5%; P2: 11.36%), and pelvis (P1: 12.4%; P2: 14.34%) decreased more than total bone mineral density. At each appointment, the participant reported breastfeeding, being physically active, but did not exercise consistently. **CONCLUSIONS:** Exclusive breastfeeding combined with an active lifestyle but no formal exercise was adequate to restore fat mass and lean mass by 12 months postpartum. Total bone mineral density decreased following both pregnancies. The baseline bone mineral density for the second pregnancy was lower than the initial baseline, but less decline post-partum.

Sex Differences On Measures Of Pulse Wave Reflection Response To Heavy Battle Rope Exercise
 Alena J. Varner, Erica M. Marshall, Jason C. Parks, Stacie M. Humm, Sarah G. Kearney, Meredith C. Paskert, J. Derek Kingsley, FACSM. Kent State University, Kent, OH.
 Email: avarner5@kent.edu
 (No relevant relationships reported)

PURPOSE: To determine if there are sex-specific responses to heavy battle rope exercise (HRE) on measures of pulse wave reflection. **METHODS:** Twenty-seven resistance-trained individuals (Men: $n=14$, Mean \pm SD: Age: 23 \pm 3 yrs; Women: $n=13$, Age: 22 \pm 2yrs) participated. All measurements were collected at Rest, and 15 (Rec1), 30 (Rec2), and 60 (Rec3) minutes following HRE. Augmentation index (AIx), augmentation index at 75bpm (AIx@75), wasted left ventricle energy (EW), and subendocardial viability ratio (SEVR) were recorded via applanation tonometry. HRE utilized six 15-second exercise bouts using a double wave pattern (180bpm), with 30-second seated recovery. Two-way repeated measures ANOVAs were used to determine sex differences across time. **RESULTS:** There were significant sex by time interactions for AIx ($p = 0.003$), AIx@75 ($p = 0.029$), and EW ($p \leq 0.001$). AIx for men was augmented compared to women during Rec1, Rec2, and Rec3 (Men= Rest: 9.4 \pm 9.6 %, Rec1: 31.4 \pm 13.1 %, Rec2: 18.3 \pm 12.4 %, Rec3: 18.6 \pm 8.3 %; Women= Rest: 10.5 \pm 10.8 %, Rec1: 21.1 \pm 10.6 %, Rec2: 12.6 \pm 7.3 %, Rec3: 7.1 \pm 5.7 %).

Alx@75 for men was augmented during Rec1, Rec2 and Rec3 compared to women (Men= Rest: 0.4 ± 7.6 %, Rec1: 33.6 ± 12.4 %, Rec2: 20.1 ± 13.3 %, Rec3:15.8 ± 9.9 %; Women= Rest: 16.8 ± 39.5 %, Rec1: 33.6 ± 12.4 %, Rec2: 20.1 ± 13.3 %, Rec3: 15.8 ± 9.9 %). EW for men was augmented compared to women during Rec1, Rec2, and Rec3 (Men= Rest: 305.4 ± 219.6 dynes/sec/cm-2, Rec1: 2153.5 ± 866.7 dynes/sec/cm-2, Rec2: 1235.3 ± 779.5 dynes/sec/cm-2, Rec3: 1212.0 ± 593.7 dynes/sec/cm-2; Women= Rest: 258.4 ± 248.2 dynes/sec/cm-2, Rec1: 1257.3 ± 656.7 dynes/sec/cm-2, Rec2: 706.1 ± 688.9 dynes/sec/cm-2, Rec3: 331.9 ± 287.2 dynes/sec/cm-2). Compared to Rest, Alx, Alx@75, and EW for men was significantly greater during Rec3, while Rec3 for women returned to Rest. SEVR had a significant main effect of time ($p \leq 0.001$), in that Rest was augmented compared to Rec1, Rec2, and Rec3 for both sexes (Men= Rest: 159.4 ± 26.0 %, Rec1: 92.3 ± 14.2 %, Rec2: 103.9 ± 27.6 %, Rec3: 127.6 ± 22.4 %; Women= Rest: 142.4 ± 25.3 %, Rec1: 83.2 ± 15.5 %, Rec2: 109.0 ± 21.3 %, Rec3: 129.3 ± 22.0 %). **CONCLUSION:** These data suggest sex differences in pulse wave velocity after HRE. There was a greater decrement of left ventricular function in men up to 60 minutes, and women recovered faster following HRE.

2119 Board #38 May 28 3:00 PM - 4:30 PM
Exercise Training Improves High Blood Pressure Variability-induced Cardiac Damage In Normotensive Rats

Ivana C. Moraes-Silva¹, Katia De Angelis², Nilsa R. Damaceno-Rodrigues³, Elia G. Caldini³, Maria Claudia Irigoyen¹. ¹Heart Institute (InCor), University of São Paulo Medical School (FMUSP), São Paulo, Brazil. ²Federal University of São Paulo (UNIFESP), São Paulo, Brazil. ³University of São Paulo Medical School (FMUSP), São Paulo, Brazil.
 (No relevant relationships reported)

High blood pressure variability (BPV) at rest is harmful to organ perfusion even if blood pressure (BP) is within normal values. Exercise training (ET) is known for its effectiveness in reducing BP and BPV; however, the effects of high BPV without sustained hypertension are unclear. **PURPOSE:** To study the effects of ET in cardiac morphofunctional parameters in an experimental model of high BPV. **METHODS:** Normotensive rats (256±4 g, mean BP 110±4 mmHg) underwent sinoaortic denervation (SAD) or sham surgery. SAD consists of baroreceptors afferent arm resection, thus increasing BPV. After 1 week of SAD, rats were divided into sedentary or trained. ET was performed on a treadmill (10 weeks, 5x/week, 60-70% of VO₂ max). After this period, BP and heart rate (HR) were directly measured (Windaq, 2kHz). Cardiovascular autonomic modulation and spontaneous baroreflex sensitivity were analyzed in frequency domain (Matlab). Echocardiography and cardiac histomorphometry were also performed. Two-way ANOVA was used to compare groups; numeric results are described when $p < 0.05$; 8 rats/group were used. **RESULTS:** When compared to control, SAD increased BPV in 5x, as well as the % of cardiac collagen in 2.5x, and the diastolic parameter isovolumetric relaxation time (IVRT) (21±1 vs. 35±1 ms); whereas it reduced VO₂ max (-20%) and the cardiac capillary density (-54%). In sham rats, ET reduced resting HR (-50 bpm/14%), while cardiac vagal modulation (+8.5%), baroreflex sensitivity (+55%), cardiac capillary density (+45%), and VO₂ max (+10%) were augmented. In contrast, ET in SAD increased both HR (~+30 bpm/8%) and cardiac sympathetic modulation (~+50%), with no alterations in baroreflex and vagal modulation. Interestingly, ET in SAD rats improved BPV (-30%), VO₂ max (+9%), IVRT (-6 ms/17%), collagen content (-29%) and capillary density (+50%) in the heart. BPV was highly associated with VO₂ max ($r = -0.74$), collagen $(r = 0.87)$ and capillary density ($r = -0.72$). **CONCLUSION:** High BPV by SAD impaired cardiac function, morphology, and autonomic nervous system. ET ability to decrease BPV was associated with better aerobic capacity and cardiac morphology, even without improvements in BP, HR and autonomic modulation. Therefore, ET-induced cardiac adaptations do not depend, at least in part, on baroreceptors signaling to central commands.

2120 Board #39 May 28 3:00 PM - 4:30 PM
The Affection Of Different Weeks Hiit And Moderate Intensity Aerobic Exercise For Cardiac Muscle'S Ampk And Pgc1 α Of Rats

Tianhao Wen, Chunyu Liang, Hao Su, Jia Shao, Guohuan Cao, Ye Gao. Beijing Sport University, Beijing, China.
 Email: 1004320180281@bsu.edu.cn
 (No relevant relationships reported)

PURPOSE: Through the research about the affection of different weeks HIIT and moderate-intensity aerobic training on cardiac muscle oxidative ability and cardiorespiratory fitness to determine the effective load of HIIT and MICT to improve the cardiorespiratory fitness. **METHODS:** 120 6-week-old male Wistar rats were randomly divided into 4 groups (N=30): 2 week Group (C), 4 week Group (D), 6 week Group (E), 10 week Group (F). Each group contains a control, moderate-intensity training with HIIT three teams, 10 rats in each group. Rats in the control group didn't exercise, the training program

of exercise group rats were depended on the Results of the maximal oxygen uptake test. 50 minutes exercise per day and 5 times per week. Rats in each group after the prescribed number of weeks were collected cardiac muscle. Protein levels of AMPK and PGC-1α were detected by Western blotting. SPSS17.0 for data analysis. **RESULTS:** 1. 2 weeks and 10 weeks of HIIT group on improving of rat cardiac muscle oxidative capacity and cardiovascular fitness has a significant impact ($P < 0.05$); 2. HIIT on aerobic capacity in rats at 10 weeks improved most significantly ($P < 0.05$), MICT on aerobic capacity of rats had no significant effect in 10 weeks; 3. The change of AMPK and PGC-1α and Vo₂max in the HIIT group are more consistent than its in the MICT group. **CONCLUSION:** 1. HIIT is more effective than Moderate-intensity continuous training in the way to improve aerobic capacity; 2. Effect of Long-term HIIT can be more pronounced in respect of enhancing aerobic capacity; 3. HIIT can promote cardiac muscle aerobic capacity through AMPK/PGC-1α Signaling Pathway.

The Pgc1 α levels in different groups				
Group	2weeks	4weeks	6weeks	10weeks
CON	1.00±0.00	1.00±0.00	1.00±0.00	1.00±0.00
MICT	1.12±0.38	1.06±0.03	0.76±0.12	1.15±0.04
HIIT	0.95±0.24	0.91±0.03	1.09±0.43	1.32±0.26

The AMPK levels in different groups				
Group	2weeks	4weeks	6weeks	10weeks
CON	1.00±0.00	1.00±0.00	1.00±0.00	1.00±0.00
MICT	1.04±0.26	1.16±0.30	0.97±0.26	1.16±0.14

COMPARISON OF THE 'SEATTLE' AND 'INTERNATIONAL' CRITERIA ELECTROCARDIOGRAM INTERPRETATION IN DIVISION II COLLEGE ATHLETES

Ludmila M. Cosio-Lima, FACSM, Lauren E. Adlof, Sarai Flores, Emily E. Grammer, Amy A. Crawley, Youngil Lee. University of West Florida, Pensacola, FL.
 Email: lcosiolima@uwf.edu
 (No relevant relationships reported)

PURPOSE: A 12-lead exercise stress test is a screening tool used to detect abnormalities that may predispose collegiate athletes to sudden cardiac death. Experts in the field have developed new standardized criteria to better interpret electrocardiogram (ECG) in athletes. The purpose of this study was to compare the Seattle criteria to the most recently created International criteria in regards to ECG abnormalities in Division II collegiate athletes. **METHODS:** Fifty-two athletes (Males = 26; Females = 26) completed cardiovascular screening with a resting 12-lead ECG analysis which was read and interpreted according to each criteria by an expert in the field of exercise science. ECGs were classified as 'normal' and 'abnormal' according to the parameters of each criteria and the abnormal condition was noted. Chi-square analysis was used to assess differences between criteria. **RESULTS:** The total number of ECGs identified as abnormal decreased from 6 (11.5%) using the Seattle Criteria to 1 (1.9%) using the International Criteria ($p < 0.05$). The most common ECG abnormality identified using the International Criteria was T wave inversion 6 (11.5%). The newer definition of pathological Q waves reduced the number of ECGs identified as abnormal from pathologic Q waves from 3 (Seattle) to 1 (International) (66% reduction; $p < 0.05$). **CONCLUSIONS:** Following the International Criteria for ECG interpretation significantly reduces the total abnormal and false-positive ECG rates in DII collegiate athletes compared to the Seattle Criteria without compromising sensitivity

Effect Of Astragalus Injection Combined With Aerobic Exercise On Myocardial Renin-angiotensin System In Diabetic Mice

Liu Tao, Xiujuan Liu. Nanjing Sport Institute, Nanjing, China.
 Email: 1406678253@qq.com
 (No relevant relationships reported)

Abstract: **PURPOSE:** This investigation aimed at investigating the synergistic effect of Astragalus injection combined with aerobic exercise on myocardial renin-angiotensin system in diabetic mice, and clarify whether the myocardial disease of diabetic mice is improved. **METHODS:** 32 6-week-old male db/db mice were randomly

divided into 4 groups, Diabetes mellitus group, Astragalus injection group, Swimming group and Astragalus injection + swimming group. Monitor the amount of drinking water, body weight and blood glucose changes. The myocardial tissue was executed after 6 weeks and the ventricular mass index was calculated; detect the angiotensin II (Ang-II), angiotensin-converting enzyme (ACE) and angiotensin converting enzyme 2 (ACE2) in each group of myocardium tissues. **RESULTS:** In addition to diabetic group, the ventricular mass index of each group was elevated ($P < 0.05$). In addition to the diabetic group, the Ang-II levels of myocardial tissues were decreased ($P < 0.05$). In addition to the diabetic group, the ACE and ACE2 levels averaged increased ($P < 0.05$). **CONCLUSIONS:** Myocardial ACE, ACE2 enzyme activity is generally low, Ang-II content is also higher than other groups, and the decrease of enzyme activity will promote the increase of Ang-II content, indicating that renin-angiotensin system is overactivated, resulting in strong vasoconstriction and myocardial ischemia and hypoxia, and eventually lead to all kinds of cardiomyopathy. After the intervention of astragalus membranaceus or aerobic exercise, the activity of ACE, ACE2 enzyme was increased and the level of Ang-II content was also significantly suppressed. Astragalus membranaceus or aerobic exercise had a positive effect on renin-angiotensin system in myocardial tissue of diabetic mice, and played a protective role in the myocardium of diabetic mice. It was speculated that there was a great deal of inhibition on renin-angiotensin system in myocardium of diabetic mice. It may be achieved by increasing the enzyme activity of ACE2 to inhibit the formation of Ang-II in diabetic myocardial tissue.

FUNDING: This study was supported by Practical Innovation training Program for College students in Jiangsu Province (201510330021Y).

Cardiorespiratory Fitness And Cardiac Autonomic Function In Brazilian Firefighters

João Paulo Araujo Barbosa, Kevin Alves Barreto, Daniel RF Saint-Martin, Edgard MKVK Soares, Mayda Castro, Rosenkranz Maciel Nogueira, Guilherme E. Molina, Luiz Guilherme Grossi Porto. *Universidade de Brasilia, UnB e Grupo de Estudos em Fisiologia e Epidemiologia do Exercício e da Atividade Física - GEAFS, Brasilia, Brazil.*
 Email: jpaulo.edfisica@hotmail.com
 (No relevant relationships reported)

INTRODUCTION: There are many ways to indirectly determine the autonomic balance, such as by means of heart rate variability, Valsalva maneuver and active orthostatic stress (AOS). In an AOS test, heart rate (HR) shows a bimodal behavior with a fast HR increase that is explained mainly by vagal withdrawal and a subsequent HR decrease, associate to a vagal reactivation and baroreflex control. Studies have shown a controversial relationship between cardiorespiratory fitness (CRF) and the cardiac autonomic function. **PURPOSE:** To correlate CRF and the vagal withdrawal response to AOS in Brazilian firefighters. **METHODS:** We evaluated 26 male military firefighters. AOS test was performed in the morning immediately before the on-duty period. A Heart Rate monitor was used to continuously record HR during AOS. Jackson's questionnaire was used to estimate CRF. The relative difference between the basal (supine) and peak HR (orthostatic) during AOS ($\% \Delta \text{HR} [t_0 - t_{\text{max}}]$) was calculated to express the vagal withdrawal in relation to basal HR. Due to a nonparametric distribution Spearman correlation test was used ($p \leq 0.05$). **RESULTS:** We observed a positive correlation ($r = 0.597, p < 0.01$) between $\% \Delta \text{HR} (t_0 - t_{\text{max}})$ and CRF (Figure 1). **CONCLUSION:** It was shown that the higher the cardiorespiratory fitness (CRF), the greater the vagal withdrawal as evaluated by $\% \Delta \text{HR} (t_0 - t_{\text{max}})$. Besides being necessary for job-task performance, higher CRF seems to be associated with an improved cardiac autonomic function in firefighters. CRF may be a protective factor for autonomic disorders in firefighters.

Figure 1: Spearman correlation between CRF and HR response during AOS (n = 26)

PURPOSE: To compare the behavior of rest heart rate (RHR) during four decades in schoolchildren

METHODS: Data were obtained from the Ilhabela Mixed Longitudinal Project of Growth and Development from Ilhabela, organized since 1978 with 2 appraisals a year, carried out during the months of May and October. Sample consisted of 262 boys from 12-14 years old, divided into 5 periods: 1978 (n = 41), 1988 (n = 43), 1998 (n = 61), 2008 (n = 52) and 2018 (n = 65). Measures included body weight, height, BMI, and Rest Heart Rate, that was measured by stethoscope before starting a cycle ergometer test. It was taken an ANOVA one-way to compare the RHR from each decade, followed by Scheffé post-hoc test; with a significant level of $p < .01$.

RESULTS: Figure 1 shows that RHR was significant higher in 1998, 2008, and 2018 when compared to 1978 and 1988. The percent delta of each decade RHR from 1998, 2008 and 2018 was 9.1%, 11.3%, and 12.4% higher than the 1978 values, respectively. RHR from 1998, 2008, and 2018 were 4.7%, 7.1%, and 8.2% higher than in 1988, respectively.

CONCLUSIONS: In 40 years there was a positive secular trend of resting heart rate among adolescents from Ilhabela. It was hypothesized that this increase may be related to changes in the students lifestyle and in the environment they live, which may have contributed to a hypokinetic behavior, reducing the level of physical fitness, and resulting in a cardiac overload.

Echocardiographic Characteristics Of Endurance And Non-Endurance Competitive Athletes

Enrique O. Prada¹, Aldo F. Longo¹, Luis A. Morita², Tomás F. Cianciulli², Enrique O. Balardini¹, Marcelo L. Cardey¹. ¹Centro Nacional de Alto Rendimiento Deportivo (CeNARD), Buenos Aires, Argentina. ²Hospital General de Agudos Dr. Cosme Argerich, Buenos Aires, Argentina.
 (No relevant relationships reported)

PURPOSE: To compare echocardiographic measures between endurance and non-endurance athletes.

METHODS: Echocardiographic studies were performed in 250 well-trained male and female subjects aged between 13 and 38 years (Age = 20.9 ± 5.5 years, BMI = 22.7 ± 3.3 kg/m²; mean ± SD). Twenty-five variables were analyzed. Statistical summaries stratified by gender and age group were initially produced. Afterwards, the subjects aged 15 years or over (n = 224) were classified into two categories according to the characteristics of their sport discipline: "Endurance" (cardiorespiratory endurance) and "Other" (Non-Endurance). Univariate comparisons between the two groups were conducted within each gender stratum in a subset of fifteen variables: Heart rate (HR), Left ventricular diastolic diameter (LVDD), Left ventricular diastolic diameter index (LVDDI), Interventricular septum thickness (IST), Left ventricular shortening fraction (LVSF), Left ventricular posterior wall thickness (LVPWT), Relative wall thickness (RWT), Left ventricular mass index (LVMI), Left auricular diameter (LAD), Aortic root diameter (ARD), Inferior vena cava diameter (IVCD), E/A ratio (EAR), E/e' ratio (E/e'), Right ventricular systolic velocity (RVS) and Left ventricular global longitudinal strain (GLS). The Student's *t*-test for independent samples was applied. Statistical significance was declared at the 0.05 level.

RESULTS: In men, statistically significant higher values were identified in the endurance group for IST (10.5 ± 0.2 vs. 9.7 ± 0.1 mm), LVPWT (9.4 ± 0.1 vs. 8.8 ± 0.1 mm), RWT (0.33 ± 0.005 vs. 0.32 ± 0.004), LVMI (117.2 ± 3.0 vs. 104.5 ± 2.3 mm) and LAD (39.2 ± 0.5 vs. 37.5 ± 0.4 mm); and in women, the endurance group had significantly lower HR values (60.1 ± 1.8 vs. 64.5 ± 1.2 beats/min), and significantly higher LVDDI (31.6 ± 0.5 vs. 29.2 ± 0.3 mm/m²) and LVMI (95.9 ± 2.6 vs. 82.4 ± 1.7 mm) values; (mean ± SE).

CONCLUSIONS: Most of the echocardiographic variables showed higher sample means in the endurance athletes, although not all the differences were statistically significant. The endurance group showed significantly higher values of left ventricular wall thickness and left auricular diameter in men, and significantly higher values in variables related to the left ventricular eccentric hypertrophy in women.

Associations Between Sedentary Behavior And Steps With Heart Rate Variability In Desk Workers

Abdullah B. Alansari¹, John M. Jakicic, FACSM¹, Christopher E. Kline¹, Matthew Muldoon¹, Molly B. Conroy, FACSM², Bethany B. Gibbs¹. ¹University of Pittsburgh, PITTSBURGH, PA. ²University of Utah, Salt Lake City, UT. (Sponsor: Dr. John Jakicic, FACSM)
 Email: abdul28@outlook.sa
 (No relevant relationships reported)

PURPOSE: More sedentary behavior (SB) has been associated with reduced heart rate variability (HRV) in blue-collar workers; however, this association has not yet been examined in desk workers who engage in high levels of SB. This study explored associations between SB and steps/day with HRV in desk workers. **METHODS:** This analysis of baseline data of a subsample of participants from an ongoing clinical trial included thirty-three insufficiently active adults (age: 43.7 ± 11.6 yr; BMI: 30.0 ± 6.3 kg/m²) with desk jobs and elevated blood pressure. An activPAL3 micro device was placed on the anterior midpoint of the thigh for one week to measure SB and steps. Total and prolonged (≥30 continuous minutes) SB and total steps/day were averaged across valid days for participants with ≥10 hr/day on ≥4 days. For HRV, beat-to-beat intervals were collected during a 10-min supine rest using a Polar V800 monitor, with the last 5 min analyzed using Kubios software to measure parasympathetic-related HRV parameters including: mean R-R intervals, root mean square of successive differences (RMSSD), standard deviation of normal R-R intervals (SDNN) and high frequency (HF). Natural-log (ln) transformation was applied for skewed HRV variables. Simple and partial Pearson's correlations between SB, steps/day and HRV parameters were calculated before and after controlling for age. **RESULTS:** Correlations were not statistically significant between total or prolonged SB with any of the HRV parameters (Table 1.). Steps/day were correlated with mean R-R intervals (r = .371; p = .034), with the correlation attenuated when controlling for age (r = .320; p = .075). No other significant correlations were detected between steps/day and other HRV parameters. **CONCLUSION:** While SB was not correlated to HRV, more steps/day were related to greater parasympathetic-related HRV in adults with desk jobs. These results may suggest that movement rather than SB should be the focus of approaches to enhance HRV.

Table 1. Correlation between sedentary behavior, steps per day and HRV parameters.

	Total sedentary time	Prolonged sedentary time (≥30 min bouts)	Steps/day
Mean R-R	r = -.200; p = .265	r = -.163; p = .364	r = .371; p = .034*
lnRMSSD	r = -.006; p = .974	r = -.094; p = .604	r = .131; p = .468
lnSDNN	r = -.052; p = .776	r = -.117; p = .515	r = .145; p = .420
lnHF	r = -.030; p = .869	r = -.076; p = .675	r = -.080; p = .658

* indicates significant correlation at p < .05; r = Pearson's correlation; lnRMSSD, natural logarithmic root mean square of successive differences; lnSDNN, natural logarithmic standard deviation of R-R; lnHF, natural logarithmic high frequency.

2127 Board #46 May 28 3:00 PM - 4:30 PM
Effect Of Aerobic Exercise On Cardiac Diastolic Dysfunction: Role Of Heat Shock Protein 27

Shunchang Li¹, Min Liang¹, Yanrong Pan¹, Manda Wang¹, Derun Gao¹, Huayu Shang¹, Quansheng Su¹, Ismail Laher². ¹Chengdu Sport University, Chengdu, China. ²University of British Columbia, Vancouver, BC, Canada. (Sponsor: Tongjian You, FACSM)
 Email: lishunchang_1983@163.com
 (No relevant relationships reported)

Purpose: To evaluate the role of heat shock protein 27 (HSP27) in the effect of aerobic exercise on cardiac diastolic dysfunction in type 2 diabetic rats.

Methods: Forty male Sprague-Dawley rats were randomly divided into four groups: control (C), aerobic exercise (A), diabetes (D), and diabetes plus aerobic exercise (DA). Type 2 diabetes was induced by feeding with a high-fat high-sugar diet for 7 weeks followed by a single intraperitoneal injection of streptozotocin (30mg/kg) in the rats. Aerobic exercise was performed on a rodent treadmill at 21m/min for 60 min, 5 days per week for 8 weeks. Metabolic factors, such as fasting blood glucose (FBG), triglycerides (TG), cholesterol (CHOL) and lipoproteins, were determined by a standard procedure. Cardiac structure and function, such as left ventricular diastolic upper diameter (LVIDd), left ventricular diastolic terminal volume (EDV) and ejection fraction (EF), were measured using echocardiography. Myocardial HSP27 protein expression and phosphorylation were determined using western blot, and myocardial HSP27-titin colocalization were determined using double immunofluorescence. Two-way ANOVAs with post-hoc tests were used to assess differences between groups.

Results: No pathological changes were observed in the myocardial structure in all four groups. Compared to the C group, the D group had significantly higher levels of FBG, TG, and CHOL (all p<0.01), and significantly lower LVIDd and EDV (both p<0.01). Compared to the D group, the DA group had significantly lower levels of FBG, TG, and CHOL (all p<0.01) and significantly higher LVIDd and EDV (both p<0.05). Interestingly, compared to the C group, the D group showed significantly lower myocardial HSP27 phosphorylation and HSP27-titin colocalization (both p<0.05), while the DA group showed significantly higher myocardial HSP27 protein expression and phosphorylation, and HSP27-titin colocalization than the D group (all p<0.01). **Conclusion:** Decreases in myocardial HSP27 phosphorylation and HSP27-titin colocalization are likely involved in early diastolic dysfunction in diabetic rats. Increased HSP27 phosphorylation and titin colocalization may be an important mechanism by which aerobic exercise restores diastolic function in diabetic rats.

Cardiac Autonomic Function Is Associated With Blood Pressure And Cardiovascular Disease Risk In Adults

Jackie Dawson, Michael Lee, Christopher Mendoza, Rachel Thomson. California State University, Long Beach, Long Beach, CA.
 Email: jacqueline.dawson@csulb.edu
 (No relevant relationships reported)

Risk of cardiovascular disease (CVD) can begin as early as young adulthood. With the prevalence of CVD in the United States expected to increase as the population ages, strategies for the early identification of CVD risk are needed to improve interventions and reduce the future burden of CVD. Cardiac autonomic dysfunction, measured non-invasively through heart rate variability (HRV), has been suggested as an early marker of CVD. Reduced HRV is associated with increased CVD risk among older adults or those with existing metabolic disease, but data are limited in young adults.

PURPOSE: This study examined the association between HRV and a commonly used CVD risk prediction variable, systolic blood pressure (SBP), and 30-year Framingham risk score as a measure of long-term CVD risk, in a cohort of young adults. **METHODS:** A total of 23 females (24.8 ± 1.9 yr) and 17 males (26.0 ± 2.3 yr) performed study measurements in one visit. Assessments included 10-minute seated HRV collection using a wearable sensor, blood pressure, waist circumference and body mass index. HRV data were filtered and visually inspected for artifacts. The root mean square of successive differences in the time domain (RMSSD) was used as the variable

of interest. The 30-year Framingham risk score was calculated from sex, age, SBP, body mass index and antihypertensive treatment, smoking, or diabetes mellitus status. Multiple linear regression was used to investigate the association between RMSSD and SBP or 30-year risk score, adjusted for sex. **RESULTS:** Hypertension was observed in 43% of females and 76% of males. RMSSD was inversely associated with SBP ($p = 0.01$, $\beta = -0.11$) and 30-year risk score ($p=0.217$, $\beta = -1.9$). Sex significantly influenced the association between RMSSD and SBP ($p<0.05$). **CONCLUSIONS:** In this limited sample, our data suggest that lower HRV is associated with higher SBP and higher CVD risk. Because 30-year risk score is designed to better discriminate long-term CVD risk from multiple factors, this supports the predictive capacity of reduced HRV as an early marker of CVD. Further research is needed to determine whether additional factors, such as race disparities, physical activity level or metabolic variables, can influence this association. Supported by NIGMS/NIH UL1GM118979, TL4GM118980 and RL5GM118978.

Utility Of Serial Short-time Indices Of HRV And Cardiac Dynamics Throughout The Day

Emily Bechke, Nathaniel Berry, Zach Kincaid, Travis Anderson, Allan Goldfarb, FACSM, Christopher Rhea, Laurie Wideman, FACSM. *University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Laurie Wideman, FACSM)
 (No relevant relationships reported)

Short-time indices of heart rate variability (HRV) and cardiac regulatory dynamics (CRD) throughout a 24-hr recording may provide an alternative to the collection of a full 24-hr recording, however, methodological approaches need to be further evaluated. **PURPOSE:** The purpose of this study was to examine the robustness of various methodological approaches of short-time indices of HRV and CRD throughout a 24-hr period.

METHODS: Eight healthy males completed two 24-hr visits. R-R intervals were recorded continuously using a heart rate monitor. Measures of HRV include the root mean square of successive R-R intervals (RMSSD) and the standard deviation of R-R intervals (SDNN), while CRD was assessed using sample entropy (SampEn). Each 24-hr recording was separated into 145 epochs to create a new time-series (HRV_{ep}). Length and position of these epochs were varied around every 10th-min: the 3-min before every 10th-min (B3), the 3-min following every 10th-min (A3), the 3-min splitting every 10th-min (S3), and the 5-min splitting every 10th-min (S5). The dimensionality and complexity of each of these epoched profiles were subsequently analyzed. Tests of equivalence (TOST) were used to compare the raw values of rMSSD, SDNN, and SampEn between epoching methods at the individual level while paired TOST tests were used to examine the dynamics of these epoched profiles between epoching methods.

RESULTS: TOST test between epoching methods of the raw values for rMSSD_{ep} and SDNN_{ep} at the individual level were equivocal ($p>0.05$), whereas SampEn_{ep} showed equality ($p<0.05$). Further analysis of paired TOST test comparing the embedding dimension and complexity of HRV_{ep} showed inequality in the optimal embedding dimension of these time-series and statistical equality ($p<0.01$) between the complexity of these time-series.

CONCLUSIONS: Epoch-by-epoch analysis of rMSSD_{ep} and SDNN_{ep} were not equal whereas SampEn_{ep} was equivalent across epoching methods. Although the optimal embedding dimension of these time-series varied between epoching methods, the complexity of these time-series were similar between methods for all indices of HRV_{ep}.

 (No relevant relationships reported)

Obesity is associated with cardiovascular autonomic dysfunction. Bariatric surgery improves cardiovascular health, which might be partly attributed to alterations in the autonomic nervous system. However, the benefits from surgery are limited, and it is

currently unknown whether exercise training can further improve cardiac autonomic regulation in post-bariatric patients. **PURPOSE:** To examine the effects of exercise training on cardiac autonomic responses in women undergoing bariatric surgery. **METHODS:** Sixty-two obese women were randomly allocated to receive either bariatric surgery (RYGB) or bariatric surgery followed by exercise training (RYGB+ET). At baseline (PRE), and 3 (POST3) and 9 (POST9) months after surgery, we assessed chronotropic response to exercise (CR%) and heart rate recovery; i.e., the decay of heart rate after 30 (HRR30s), 60s (HRR60s) and 120s (HRR120s) after a maximal exercise test. The 6-month exercise intervention started at POST3 for RYGB+ET, while RYGB followed standard care.

RESULTS: Analysis of relative changes (Δ from POST9-PRE) revealed higher CR% ($\Delta=8.56\%$, CI95% 0.22-19.90, $P=0.0445$), HRR30s ($\Delta=12.98$ beat/min, CI95% 4.29-21.67, $P=0.01$), HRR60s ($\Delta=22.95$ beat/min, CI95% 11.72-34.18, $P=0.01$) and HRR120s ($\Delta=34.54$ beat/min, CI95% 19.91-49.17, $P<0.01$) in the exercised group. Both groups demonstrated similar reduction in the frequency of individuals showed incompetence chronotropic (defined as chronotropic response less than 80%) at POST3 and POST9). The proportion of participants with blunted HRR decreased at POST3 in both groups; interestingly, exercise training further decreased this proportion at POST9 from 56% to 5%. Moreover, the proportion of blunted HRR in RYGB+ET was significantly lower than in RYGB at POST9 (5% vs. 31%, $P=0.045$, respectively). **CONCLUSIONS:** A 6-month exercise training program is an effective strategy to improve cardiac autonomic responses during and post-exercise recovery in obese women undergoing bariatric surgery. These findings reinforce the relevant cardioprotective role of exercise for post-bariatric patients. Clinicaltrials.gov: NCT02441361

Effects Of Weight Stigma On Cardiovascular Reactivity Among Women With High And Normal Blood Pressure

Gregory A. Panza¹, Rebecca M. Puhl², Beth A. Taylor, FACSM¹, Burak Cihoroz², Mary Himmelstein², Antonio B. Fernandez³, Linda Pescatello, FACSM². ¹University of Connecticut / Hartford Hospital, Storrs, CT. ²University of Connecticut, Storrs, CT. ³Hartford Hospital, Hartford, CT. (Sponsor: Linda Pescatello, FACSM)
 Email: Gregory.Panza@uconn.edu
 (No relevant relationships reported)

In a recent systematic review, we reported evidence that exercise and nutrition professionals stigmatize their patients due to their weight in 81% of 31 studies. Being weight stigmatized is associated with adverse cardiovascular health consequences for unclear reasons; but may be due to the heightened cardiovascular reactivity that accompanies obesity and hypertension. **PURPOSE:** We examined the influence of two video exposures, one containing scenes of weight stigma (STIGMA) and the other non-stigmatizing neutral (NEUTRAL) scenes, on cardiovascular reactivity assessed by resting and ambulatory blood pressure (ABP) and heart rate (HR), among women with obesity and high blood pressure (HBP; $n=24$) or normal BP (NBP; $n=25$). **METHODS:** Women completed a screening visit and two randomized visits which involved watching a 10-min STIGMA and NEUTRAL video exposure. Laboratory BP and HR were measured before, during, and after the videos. ABP and HR were measured upon leaving the laboratory for the awake (10hr), sleep (9hr), and 19hr. A repeated measures ANCOVA tested the difference in BP and HR changes from baseline between the BP groups after STIGMA vs NEUTRAL controlling for BMI and baseline BP and HR in the laboratory and over ambulatory conditions. **RESULTS:** Women with HBP (systolic/diastolic BP [SBP/DBP]= 122.9 ± 13.6/73.5 ± 11.2mmHg) were 37.5 ± 9.1yr and obese (Body Mass Index [BMI] = 37.8 ± 6.1kg·m²); women with NBP (SBP/DBP=106.9 ± 7.4/65.0 ± 7.1mmHg) were 34.1 ± 8.9yr and obese (BMI= 33.6 ± 4.9kg·m²). Laboratory SBP/DBP increased 5.5 ± 7.3/2.4 ± 8.8mmHg more in HBP than NBP after STIGMA vs NEUTRAL ($P<0.05$), with no difference in HR ($P>0.05$). ABP increased more in HBP than NBP over sleep (SBP / DBP= 4.2 ± 20.6/4.7 ± 14.2mmHg; $P<0.05$) and 19hr (SBP / DBP = 0.9 ± 15.2/0.4 ± 10.8 mmHg; $P<0.05$) after STIGMA vs NEUTRAL. During sleep, HR increased 7.5 ± 15.7bpm more in HBP than NBP after STIGMA vs NEUTRAL ($P<0.05$). **CONCLUSION:** Exposure to a weight stigma video resulted in greater cardiovascular reactivity in women with obesity and HBP than NBP in the laboratory and under ambulatory conditions, most notably during sleep. Our findings reveal the importance of educating health professionals about weight stigma, and its immediate, yet persistent adverse cardiovascular health effects, and developing interventions to mitigate weight stigma.

The Influence Of Social Evaluation On Heart Rate Variability And Motor Performance: A Study Of “Real-Life” Competition

Kyle F. Pietro, Michelle E. Costanzo, Ronald N. Goodman, Li-Chuan Lo, Hyuk Oh, Jeremy C. Rietschel, Mark Saffer, Trent Bradberry, Jose Contreras-Vidal, Amy Hauffer, Bradley D. Hatfield, FACSM. *University of Maryland, College Park, MD.* (Sponsor: Dr. Bradley Hatfield, FACSM)
 Email: kpietro@umd.edu

(No relevant relationships reported)

It is well known that stress affects performance. Heart rate variability (HRV), which has become a general indicator of stress, can be measured to examine autonomic balance. **PURPOSE:** To examine HRV in participants to determine how competitive stress affects performance. **METHODS:** Participants (n=17) from the University of Maryland Reserve Officers’ Training Corps (ROTC) program completed two testing sessions: a performance alone condition (PA) and a competition condition (C). Participants completed a dry-fire pistol shooting task of 40 shots per condition. PA condition was executed without any evaluation of performance. C condition involved direct comparison to another study participant as well as superior officer observation and monetary compensation. Electrocardiogram (EKG) was collected using a Thought Technology Procomp2 system. EKG was sampled at 256 Hz through a single chest lead. HRV was analyzed through QRSTool and Kubios HRV. HRV measures were SDNN and RMSSD. **RESULTS:** SDNN decreased by condition (F (1, 16) = 3.668, p = .074, d = 0.464). RMSSD decreased by block, but not by condition (F(1, 16) = 4.557, p < .05, d = 0.517). Cortisol response ANOVA revealed a significant main effect of condition (F (1, 16) = 12.02, p = .003, d = 1.05) such that cortisol was higher during C compared to PA. **CONCLUSION:** The decrease in SDNN indicates a decrease in HRV in response to increased stress. This decreased HRV reflects a change in autonomic balance which is negatively correlated with adaptability and resilience. The decrease in RMSSD represents decreased parasympathetic modulation of heart rate. Although not measured directly, it is likely that participants experienced moderate fatigue throughout blocks. As cerebral cortical activity increased during C, one can speculate that the difference observed was influenced by the shift toward lower parasympathetic activity (i.e. reduced afference to the cortex).

2133 Board #52 May 28 3:00 PM - 4:30 PM
Caffeine In Conjunction With Resistance Exercise On Vagal Modulation In Resistance-trained Women

Emily K. Erb, Therese Smith, Erica M. Marshall, Jason C. Parks, Stacie M. Humm, Meredith C. Paskert, Sarah G. Kearney, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*
 Email: eerb4@kent.edu

(No relevant relationships reported)

PURPOSE: To examine the effects of caffeine alone, or in conjunction, with acute resistance exercise, in resistance-trained women on performance and measures of vagal modulation.

METHODS: Eleven resistance-trained women (Age Mean±SD: 24±4yrs) consumed either a placebo (PL) or caffeine (4mg/kg) 72 hours apart, in a double-blind, crossover fashion. Forty-five minutes following supplementation, participants performed two sets of 10 repetitions at 75% 1-repetition maximum (1RM), and one set with repetitions to failure at 70% 1RM on the squat and bench press. Log transformed root mean square of successive differences (lnRMSSD), and high frequency power (lnHF), as well as sample entropy (SampEn), and Lempel-Ziv entropy (LZEn) were assessed at rest (Rest1), 45 minutes post-consumption (Rest2), immediately post-exercise (Post1), and 10 minutes post-exercise (Post2). Two-way ANOVAs were used to analyze the effects of condition (PL, caffeine), across time (Rest1, Rest2, Rec1, Rec2).

RESULTS: The repetitions on the fatiguing set were similar between conditions for the squat (p=1.0), and the bench press (p=0.7). There were no significant condition by time effects for vagal tone. There was a significant main effect of time (p=0.0001) for lnRMSSD (Rest1: 4.52±0.73ms; Rest2: 4.48±0.64ms; Rec1: 2.72±0.66ms; Rec2: 2.28±0.55ms) such that it significantly decreased during Rec1 and Rec2 compared to Rest1 and Rest2. There was a significant main effect of time (p=0.0001) for lnHF (Rest1: 8.12±1.23ms²; Rest2: 8.00±1.09ms²; Rec1: 4.79±2.50ms²; Rec2: 4.02±1.02 ms²) with it decreasing at Rec1, and Rec2, compared to Rest1 and Rest2. There was a significant main effect of time (p=0.0001) for SampEn (Rest: Rest1: 1.43±.19; Rest2: 1.40±0.19; Rec1: 1.09±0.32; Rec2: 1.09±0.31) such that SampEn was significantly decreased compared to Rest at Rest2, Rec1 and Rec2. Additionally, there was a significant main effect of time (p=0.004) for LZEn (Rest1: 0.73±.09; Rest2: 0.77±0.06; Rec1: 0.66±0.13; Rec2: 0.54±0.16) with Rec2 being significantly attenuated compared to Rest2.

CONCLUSIONS: These data demonstrate that 4mg/kg of caffeine consumption does not have an ergogenic effect. In addition, when performed in conjunction with resistance exercise, it does not further decrease measures of vagal modulation in resistance-trained women.

Sleep Quality Is Associated With Nighttime Heart Rate Variability In Young Adults

Emerson E. Bennett¹, Lauren Q. Higgins², Simon Higgins¹.
¹*Elon University, Elon, NC.* ²*University of North Carolina at Greensboro, Greensboro, NC.* (Sponsor: Eric Hall, FACSM)
 Email: ebennett11@elon.edu

(No relevant relationships reported)

Heart rate variability (HRV) reflects autonomic nervous system function, and low nighttime HRV is linked to reduced parasympathetic control. Optimal parasympathetic function is important for the induction and maintenance of sleep, overall wellbeing, and is inversely associated with chronic disease. In young adults, 60% of whom report poor sleep quality, disrupted parasympathetic function may reflect suboptimal health and lifestyle behaviors. While there is an established relationship between physical activity (PA), stress, and nighttime HRV, the associations between HRV and other lifestyle-related factors such as sleep quality and social jet lag (SJL) in young adult populations are yet to be determined.

PURPOSE: The purpose of this study was to determine the relationship between nighttime HRV and sleep characteristics in young adults.

METHODS: Healthy young adults (n=33, 18.6 ± 0.7 years, 69.6% female) wore a chest-strap heart rate monitor for 24 hours and a triaxial accelerometer on the non-dominant wrist for 7 days during free-living PA and sleep. Average sleep duration and SJL were determined from objective sleep data, with SJL calculated as the difference in hours between the midpoint of sleep on weeknights (school) and weekend (free) nights. The Pittsburgh Sleep Quality Index (PSQI) and Perceived Stress Scale were used as subjective measures of sleep quality and stress. Nighttime HRV outcomes were calculated using R-R intervals between the hours of 1:00 AM - 5:00 AM. Linear regression assessed multivariate relationships among sleep duration, quality, SJL, and HRV while controlling for moderate-to-vigorous PA and perceived stress.

RESULTS: Independent of average sleep duration and SJL, perceived sleep quality was associated with the HRV outcomes low frequency (LF; B= -10.62 ± 4.85, 95% CI: -20.56, -.67) and high frequency power (HF; B= 10.55 ± 4.84, 95% CI: .61, 20.49). Following control for PA and stress, these relationships remained significant and the association between SJL and LF/HF ratio approached significance (B= -.33 ± .18, 95% CI: -.69, .04).

CONCLUSIONS: Our findings suggest that both LF and HF HRV components are related to sleep quality in young adults, highlighting a potential relationship between sleep quality and nighttime autonomic nervous system function.

Racial Differences In Selected Mechano-sensitive Micro-RNAs

Maitha Aldokhayyil, Dulce Gomez, Adelola Adeyemo, Michael Brown, FACSM. *Auburn University, Auburn, AL.*

(No relevant relationships reported)

Endothelial cells (ECs) are constantly exposed to hemodynamic shear stress that can influence vascular signaling. High laminar shear stress (HLSS), an exercise mimetic, upregulates atheroprotective genes such as Kruppel-like factor 2 (KLF2), whereas disturbed flow and oscillatory SS upregulate proatherogenic genes such as vascular adhesion molecule-1 (VCAM-1). Micro-RNAs (miRs) are small non-coding RNAs that regulate gene expression. Current evidence has identified mechano-sensitive miRs that regulate shear-induced gene expression and ultimately control endothelial function. Moreover, we have previously demonstrated the efficacy of HLSS in attenuating endothelial dysfunction predominantly seen in African American (AA) ECs compared to Caucasian (CA) ECs.

Purpose: To investigate potential racial differences in the expression of selected mechano-sensitive miRNAs in response to HLSS.

Methods: Human umbilical vein endothelial cells (HUVECs) from two AA donors and two CA donors were cultured and exposed to HLSS (20 dynes/cm²) for 24hr using a cone and plate viscometer. Total RNA was harvested to assess the effect of HLSS on the expression of miR-21, miR-126* and miR-92-a.

Results: We report a significant increase in miR-92-a expression with HLSS in both AA and CA HUVECs (~ 2-fold difference, p= .005). Additionally, miR-92-a tended to be higher in AA ECs compared to CA ECs under both conditions. However, there was no significant difference in miR-21 or miR-126* expression between AA and CA ECs nor control and HLSS conditions.

Conclusion: Despite the recognition of miRNAs as important regulators in vascular physiology, evidence is still lacking on their association with higher prevalence of endothelial dysfunction in AA. It is highly important to identify the role they play, as understanding the molecular mechanisms driving racial differences in endothelial function can help develop better targeted prevention and treatment strategies.

Is The Hexosamine Biosynthesis Pathway Affected By Inflammation In Endothelial Cells?

Adelola O. Adeyemo, Dulce H. Gomez, Maitha A. Aldokhayyil, Michael D. Brown, FACSM. *Auburn University, Auburn, AL.*
Email: aoa0005@auburn.edu
(No relevant relationships reported)

Excessive addition of β -linked N-acetylglucosamine (O-GlcNAc) via the hexosamine biosynthesis pathway (HBP) occurs with diabetes and decreases in muscles with exercise. HBP flux increases inflammation and may be specifically important in the activation phase of the inflammatory response. Inflammation plays a key role in insulin resistance and hyperglycemia (HG), with the process contributing to the development of diabetes and associated complications. β -cell development and differentiation are affected by the HBP, and O-GlcNAc has been indicated in insulin secretion from the pancreas (1). **PURPOSE:** We explored whether in the absence of HG, an inflammatory insult, can affect key factors in this pathway and total O-GlcNAcylation within the endothelium. Because African Americans are overrepresented in conditions involving chronic inflammation, potential racial differences were also examined. **METHODS:** Human umbilical vein endothelial cells (HUVECs), n=6, were stimulated with 10ng/mL of tumor necrosis factor alpha (TNF α) for 4 hours, or treated as a control. Western blot procedures were used to measure expression of the HBP rate-limiting enzyme (GFAT) and the transferase that adds the end-product onto proteins (OGT). Total protein O-GlcNAcylation (O-GlcNAc) was also measured. **RESULTS:** With TNF α stimulation, there was no difference in GFAT ($0.63 \pm .09$ vs $0.62 \pm .08$, p=.89), OGT ($0.49 \pm .09$ vs $0.41 \pm .08$, p=.56), nor total O-GlcNAc ($1.56 \pm .38$ vs $1.77 \pm .42$, p=.71) expression compared to controls. There were no racial differences found among the various conditions (p>.05) with either of the proteins examined.

CONCLUSIONS: The HBP is not altered with acute inflammation in endothelial cells (ECs), with no racial differences additionally found. Low-grade inflammation vitally contributes to diabetes, atherosclerosis, and their complications, with the HBP playing a role in each. We conclude that HG may be necessary to work in conjunction with inflammation to increase protein O-GlcNAcylation in ECs. Although increased flux through the HBP has been shown to upregulate inflammation, the reverse relationship cannot be confirmed. Future research is needed to examine links between this pathway, various conditions, and the ability of exercise to alter it within the endothelium.

Exercise Preconditioning Alleviate LPS Induced Acute Heart Injury Through GCN2 Pathway

Xin Xu, Zhongguang Sun, Xiaoci Zheng, Linlin Zhao, Jing Jing, Guo Lu. *Shanghai University of Sport, Shanghai, China.*
Email: xxu2000@outlook.com
(No relevant relationships reported)

Exercise preconditioning may protect against cardiac injury induced by lipopolysaccharide (LPS), but the mechanism is unresolved.

PURPOSE: This study aims to explore whether the general control nonderepressible 2 kinase (GCN2) gene is associated with the protective effect of exercise preconditioning.

METHODS: 8 weeks old male GCN2 knockout (KO, n = 40) and wild type control with C57BL/6J background (C57, n = 40) mice were respectively divided into 4 groups: control, LPS (L), exercise preconditioning (E) and exercise preconditioning LPS (EL). Mice in the exercise groups performed exercise for 8 weeks. After exercise, all mice were administered an equal volume of LPS (10 μ g/g body weight) or saline. Heart function were measured by Vevo1100 small animal echocardiography 6 hours later followed by immediately tissue collection for Western blots and histological analysis.

RESULTS: Exercise preconditioning was observed to improve cardiac dysfunction evaluated by ejection fraction (EF) value (C57 L: 50.34 ± 6.94 vs. C57 EL: 59.32 ± 3.63 , p<0.05) and also significantly decreased the expression levels of GCN2, phosphorylation of eukaryotic translation initiation factor 2 α (p-eIF2 α) and activating transcription factor 4 (ATF4) in C57 mice induced by LPS (p<0.05). Moreover, GCN2 KO decreased cardiac dysfunction induced by LPS in sedentary mice. The cardiac dysfunction in the GCN2 KO EL group were lower than that in C57 EL group, and the expression of GCN2, p-eIF2 α and ATF4 in the GCN2 KO EL group was significantly lower than that in C57 EL group (p<0.05).

CONCLUSION: Exercise preconditioning alleviated cardiac injury induced by LPS. GCN2 KO also improved cardiac injury. Exercise preconditioning promoted the effect of GCN2 KO in alleviating cardiac injury, GCN2 and eIF2 α /ATF4 pathway play an important role in the process.

Postnatal Growth Restriction In Mice Alters Cardiac Mitochondrial Energetics

Joseph R. Visker, Eric Leszczynski, Austin Wellette-Hunsucker, Jason N. Bazil, David Ferguson. *Michigan State University, East Lansing, MI.*
Email: viskerjo@msu.edu
(No relevant relationships reported)

Postnatal growth-restriction (PGR) is associated with increased risk of cardiovascular mortality. We hypothesize that nutrient restriction alters metabolism leading to cardiac failure. **PURPOSE:** To determine the effect of PGR on mitochondrial respiratory capacity (JO₂). **METHODS:** FVB mouse dams were fed a control(CON: 20% protein), or a low-protein(LP: 8% protein) isocaloric diet 2-weeks before mating. LP-dams produce 18% less milk and pups nursed by LP-dams undergo growth restriction. At postnatal day (PN) 1, pups born to dams fed the CON diet were crossed to LP-dams(PUN; postnatally undernourished) or a different CON-dam. At PN21, all mice were weaned to the CON-diet. On PN22 or PN80, mice were weighed, euthanized, and hearts removed. Hearts were weighed and cardiac mitochondria were isolated via differential centrifugation. Respiration was measured through high-resolution respirometry in the presence of 5 mM pyruvate and 1 mM L-malate(PM). Two-way ANOVAs were performed with the main effects of diet (CON vs. PUN) and age(PN22 vs. PN80) to compare, body-mass, heart-mass, and JO₂. An α level of 0.05 was set *a priori*, and if necessary, a Tukey's HSD post hoc test was used for multiple comparisons. **RESULTS:** PGR caused significant diet and age effects (p<.001) on final body-mass between CON (PN22: 12.01 ± 0.83 g; PN80: 23.51 ± 2.95 g) and PUN groups (PN22: 8.45 ± 0.61 g; PN80: 21.32 ± 3.42 g). Heart-mass was also significantly reduced (p<.001) in PUN (PN22: 0.06 ± 0.01 g; PN80: 0.11 ± 0.012 g) compared to CON (PN22: 0.08 ± 0.007 g; PN80: 0.12 ± 0.01 g) across the lifespan. LEAK state JO₂ was significantly higher (p<.001) at both time-points in PUN (PN22: 46.48 ± 4.25 nmol/mg/min, PN80: 48.74 ± 8.34 nmol/mg/min) compared to CON (PN22: 36.15 ± 5.60 nmol/mg/min, PN80: 38.23 ± 2.74 nmol/mg/min). The respiratory control ratio (RCR) was significantly reduced (p=0.0005) in PUN (PN22: 7.81 ± 0.48 , PN80: 7.32 ± 1.48) compared to CON (PN22: 9.25 ± 0.73 , PN80: 9.14 ± 0.74). **CONCLUSIONS:** PGR decreased body and heart-mass across the life span and increased LEAK state JO₂ in the presence of PM, indicating mitochondrial impairment at PN22 and PN80. PGR caused reductions in RCR, which may cause CVD, thus PGR increases CVD risk through uncoupling of mitochondria. Exercise may improve mitochondrial function in PGR mouse hearts.

The Role Of Exercise Intensity In Cell Signaling: Is There A Repeated-bout Effect?

Ciara Terry, Ethan Ostrom, Nora Dunbar, Tinna Traustadóttir. *Northern Arizona University, Flagstaff, AZ.*
(No relevant relationships reported)

PURPOSE: Acute exercise elicits a temporary change in redox balance resulting in activation of antioxidant related gene expression and enzymes. We have previously shown in men that the type of acute exercise stimulus, constant workload (CW) vs. high intensity interval protocol (HIIP) results in different redox responses despite no differences in mean VO₂. The present study tested whether these results translate to women. In addition, we asked whether the responses are amplified through a repeated bout effect, by comparing the responses after 1 bout to those after 3 bouts. It was hypothesized that HIIP would render greater cell signaling response compared to CW and that differences would be amplified after 3 sessions.

METHODS: Healthy women ages 30-45y participated in this study in a randomized, cross-over design (n=12, projected) with a 2-week washout period between trials. Each participant completed a VO₂max on a cycle ergometer to establish the workload for the exercise trials. Subjects were randomized to complete either CW or HIIP sessions first. Each trial occurred every other day for 5 days. A second VO₂max was performed prior to the second trial to ascertain that VO₂max had not changed from baseline. CW consisted of 30-min of cycling at 70% VO₂max. HIIP consisted of a 9-min ramp-up, 7 intervals of 1-min "all out" intervals at 90-100% VO₂max followed by 2-min recovery for a total of 30-min of cycling. Blood draws were taken pre-, and 10-, 30-, and 60-min post exercise during the first and third exercise session of each trial. Cell signaling was measured by nuclear localization of Nrf2 as well as protein abundance of GCLC and GSR in PBMCs. GR enzyme activity was measured in erythrocyte lysate.

RESULTS: To date, 5 women have enrolled in the study and testing is still underway. The average intensity of the CW trial is 70.3% and the average intensity of the HIIP intervals is 91.7% $\dot{V}O_{2\max}$. The early data show a trend for increased nuclear Nrf2 and GSR protein abundance HIIP compared to CW, and an amplification of the response after 3 sessions.

CONCLUSION: These preliminary data suggest that delivering an exercise stimulus in short "pulses" of high intensity such as the HIIP elicits a greater protective signaling response as compared to a block of moderate CW exercise, and furthermore that these effects are amplified by a repeated bout effect.

2141 Board #60 May 28 3:00 PM - 4:30 PM
Cholesterol Efflux Gene Expression In Peripheral Blood Mononuclear Cells Following High Intensity Interval Exercise

Natalie Gadaleta, Danielle Martin, Carolyn Brandt, Grace Basralian, Matthew Barberio. *George Washington University, Washington, DC.* (Sponsor: Jennifer Sacheck, FACSM)

(No relevant relationships reported)

Reverse cholesterol transport (RCT) is critical to the regulation of blood cholesterol levels and prevention of macrophage foam cell formation. A critical step in RCT is the efflux of cholesterol from macrophages to high-density lipoprotein (HDL). Numerous studies have shown exercise to regulate HDL quantity and function, but little is known about how exercise affects the expression of cholesterol efflux genes in circulating monocytes. **Purpose:** To determine changes in mRNA expression of cholesterol efflux genes (ATP-Binding Cassette A1, ABCA1; ATP Binding Cassette G1, ABCG1; mitochondrial sterol 27-hydroxylase, CYP27A1) in peripheral blood mononuclear cells (PBMCs) following a single bout of high intensity interval exercise. **Methods:** Six (Female = 4, Male = 2) healthy participants (Age = 25 ± 6 yr, BMI = 26.1 ± 4.1 kg/m², $\dot{V}O_{2\max}$ = 36.4 ± 7.4 ml x kg x min⁻¹) completed a single bout (work load = 300 kcal) of high intensity interval exercise (repeated intervals of 3 min @ 55% $\dot{V}O_{2\max}$ + 1 min @ 110% $\dot{V}O_{2\max}$). RNA was isolated from PBMCs from whole blood prior to (PRE), immediately following (POST), two hours following (POST-2) and 24 hours following (POST-24) exercise. Expression levels of ABCA1, ABCG1, and CYP27A1 were analyzed via RT-qPCR. Gene expression fold changes, in comparison to PRE, were determined via the delta-delta C_t method and analyzed via Student T-Tests. Significance was set a priori as alpha = 0.01 to correct for multiple testing. **Results:** Exercise did not significantly modify ABCA1 (Fold Change = 0.8 ± 0.5 (POST), 0.9 ± 0.7 (POST-2), and 1.3 ± 1.1 (POST-24)) at any time point following exercise. ABCG1 expression was elevated POST (1.6 ± 0.9; p < 0.001), POST-2 (1.4 ± 0.8; p = 0.01), and POST-24 (1.5 ± 0.5, p = 0.001) following exercise. CYP27A1 expression was unaltered by exercise at all time points (0.8 ± 0.2, 1.4 ± 1.2, 1.5 ± 2.3; all p > 0.01). **Conclusion:** ABCG1 plays a significant role in maintaining cellular cholesterol levels through the efflux of cholesterol from the intracellular compartment to HDL. Our results show elevations in PBMC ABCG1 expression following a single bout of high intensity interval exercise. Along with improved lipid profiles (e.g. increased HDL concentrations), exercise may promote increased cholesterol efflux from monocytes and macrophages by upregulation of cholesterol efflux genes.

Effect Of Cardiac Muscle Cells Secretome, With And Without Loading Preconditioning, On Hypoxia/Reoxygenation Injury

Argyro Papadopetraki, Evangelos Zevolis, Antonios Chatzigeorgiou, Maria Maridaki, Michael Koutsilieris, Anastassios Philippou. *National and Kapodistrian University of Athens, Athens, Greece.*

Email: arg.papadopetraki@gmail.com

(No relevant relationships reported)

Reperfusion after myocardial infarction (MI) can worsen cardiac tissue damage and in vitro models of hypoxia/reoxygenation (H/R) have been developed to simulate the in vivo ischemia/reperfusion injury. Cardiac muscle stem cells have been used for regeneration after MI due to their paracrine actions in improving myocardial cell survival and function, while interestingly, mechanical loading of cardiac muscle cells may modulate their secretome. **PURPOSE:** The present study investigated the cardiac muscle cells' paracrine effects in H/R, by treating them with the secretome of mechanically loaded or unloaded cells, in vitro.

METHODS: H9C2 cardiomyoblasts were cultured on elastic membranes and underwent a cyclic stretching (12% elongation at 0.25 Hz for 12h) and then their secretome was collected (stretch media, SM). Secretome of unstretched cardiomyoblasts were also collected (non-stretch media, NSM). Cardiomyoblasts were subjected to 6 h of hypoxia followed by 8 or 4 h of reoxygenation (H/R) while during reoxygenation, they were treated either with SM or NSM. Cell apoptosis was subsequently assessed by MTT assay and flow cytometry.

RESULTS: After the hypoxia period, cell viability rate was 98±9%, without differing from the normoxia group (p>0.05). However, after 8 or 4 h of reoxygenation, the

viability rate was reduced to 51±10% (p<0.01) and 74±10% (p<0.001), respectively. In addition, the percentage of early apoptotic cells was 36% (p<0.001) after 6 h of hypoxia/4 h of reoxygenation (H/R) as assessed by MTT assay. The viability rates in the same H/R protocol increased from 74±10% to 92±10% and 80±2% in SM- and NSM-treated cells, respectively, without exhibiting differences with the normoxia group (p>0.05). Interestingly, a significantly higher viability was observed only in the cells treated with the SM compared to the non-treated cells after H/R injury (p<0.05). **CONCLUSIONS:** Our findings suggest that cardiomyocytes are susceptible to H/R-induced injury, while the cell death rate depends on the duration of reoxygenation. Moreover, cardiomyoblasts' secretome inhibits their apoptosis after H/R injury while their mechanical load "preconditioning" appears to boost the anti-apoptotic effects of their secretome, implying the beneficial paracrine action of cardiac muscle cells due to mechanical loading.

EFFECT OF REGULAR EXERCISE ON EXPRESSION OF K_{ATP} CHANNELS IN HEART OF DIABETIC RATS

Silvestre Cardiel-Gutiérrez, Sergio Márquez-Gamiño, Karla S. Vera-Delgado, Victor H. Cordova-de los Santos, Fernando Sotelo-Barroso, Cipriana Caudillo-Cisneros, Elizabeth Sánchez-Duarte. *Universidad de Guanajuato, León, Mexico.*

(No relevant relationships reported)

There is abundant evidence that ATP sensitive potassium (K_{ATP}) channels play cytoprotective role in cardiac myocytes, allowing the cell to couple metabolic state to electrical activity of the cell membrane. In cardiac myocytes Kir6.2/SUR2A are the major subunits expressed. However, expression or function of K_{ATP} channels has been found to be impaired in the presence of persistent hyperglycemia in diabetes mellitus (DM). While regular exercise can improve hyperglycemic status in DM, its impact on the expression of KATP channels subunits in heart is unknown.

PURPOSE: To assess the effect of regular exercise on expression of K_{ATP} channel subunits in heart of streptozotocin-induced diabetic rats.

METHODS: Male Wistar rats (25 days old) were randomly divided into four groups, among them: sedentary control, trained control, sedentary diabetic, trained diabetic. Diabetes was induced by a single streptozotocin injection (100 mg/kg body weight), animals with fasting blood glucose levels ≥ 300 mg/dL were considered as diabetic. Groups with training program performed exercise on a treadmill (30 minutes daily, 5 days/week) for 8 weeks. At the end of the intervention, two subunits of cardiac KATP channel (SUR2A and Kir 6.2) were analyzed as indicators and quantitative analysis of these subunits was achieved with real-time RT-PCR.

RESULTS: In control conditions, the regular exercise reduced Kir6.2 subunit mRNA levels significantly (76%; p=0.045) in heart. In diabetes, reduced Kir6.2 expression was also observed, and there was no difference in expression levels between sedentary diabetic and trained diabetic groups (P > 0.05). Otherwise, relative mRNA expression of the subunit SUR2A was increased in both sedentary diabetic and trained diabetic groups (80.33% and 86.08%, respectively).

CONCLUSION: Collectively, our data demonstrate that the regular exercise modifies expression of K_{ATP} channel subunits of heart only in control conditions. However, the gene expression patterns of K_{ATP} channel subunits are different during diabetes, by increased SUR2A and decreased Kir6.2, which was not modified by exercise. These results may provide an opportunity to understand mechanisms leading to diabetic cardiomyopathy during stress and exercise in DM.

Patient-Child Obesity Program Causes Delayed But Significant Improvement In Body Composition Among At-Risk Youth

Stephanie Ta, Cynthia Villalobos, Courtney D. Jensen, Gigi Lee, Tristan J. Kittinger, J. Mark VanNess. *University of the Pacific, Stockton, CA.*

Email: s_ta2@u.pacific.edu

(No relevant relationships reported)

More than 13 million U.S. children are obese; complications are expected to progress throughout adulthood, increasing the risk of premature mortality. Although proper nutrition and exercise provide short and long-term health benefits, translating this information to a community-setting has been largely ineffective. It is important to identify programmatic variables that demonstrate success in weight management.

PURPOSE: To observe the effect of a family-oriented exercise and nutritional intervention on body composition in overweight and obese children and adolescents. **METHODS:** Twelve subjects (ages 7-16) were enrolled in a childhood obesity program upon referral by their primary care physician. Subjects engaged in 45 min of aerobic and flexibility training twice weekly for 18 weeks. Each exercise session was followed by 30 min of nutritional counseling. Body mass index (BMI), waist circumference (WC), hip circumference (HC), and body fat percent (BF%) were measured throughout the intervention. One-way repeated measures ANOVA determined anthropometric differences at baseline, midpoint, and at the end of the intervention. **RESULTS:** Subjects were 12.3±2.4 years old and 44.4% were obese, having a mean BMI of 29.8±4.5 kg/m², BF% of 38.6±6.8%, HC of 99.85 cm, WC of 96.10 cm, and hip-to-waist ratio of 0.96. From baseline to follow-up, subjects decreased BMI by 1.0 kg/m² (p=0.011), WC by 4.69 cm (p=0.031), and hip-to-waist ratio by 0.05 (p=0.043); the reduction in BF% failed to reach significance (p=0.060). Repeated measures ANOVA identified reductions in bodyweight (1.09 kg; p<0.001), WC (3.44 cm; p=0.049), and hip-to-waist ratio (.05; p=0.037) between weeks 9 and 18. Differences for the same measurements between weeks 1 and 9 were insignificant (p>0.05). **CONCLUSION:** Despite our small sample, a combined exercise and nutritional counseling intervention improved anthropometric profiles of obese and overweight children and adolescents over the course of 18 weeks. The greatest improvements took place after 9 weeks, indicating the importance of perseverance when seeking body composition improvement in this demographic.

**Influence Of Sports Games On Children's
 Coordination Ability And Lower Limb Muscle Strength**

Ye Zhang, Boqian Sun. *Qijing Normal University, Qijing, China.*

Email: zhangye5337@126.com
 (No relevant relationships reported)

PURPOSE: to explore the influence of the developed sports game intervention programs on children's physical coordination and lower limb strength, and to compare the effects of routine gymnastics and sports game intervention, so as to better develop children's physical coordination and lower limb strength, and provide effective intervention programs in line with the characteristics of children's physical and mental development. **METHODS:** 48 children aged 4-5 were selected and randomly divided into two groups based on teaching classes - sports game group and gymnastics group - each with 24 children. The developed sports game programs were adopted to intervene children of the sports game group. The intervention period was 4 weeks, 3 times a week, 30 minutes each time. In the same intervention cycle and intervention time, children in the gymnastics group did basic gymnastics. **RESULTS:** repeated measures of variance were analysed to compare the changes of children's physical coordination and lower limb strength in different groups before and after the intervention. The results showed that both the children in the sports game group and the gymnastics group took less time in the continuous jumping test after the intervention than before the intervention (sports game group: 8.94s±1.86s vs. 5.78±0.99s, p<0.05; gymnastics group: 10.04s±2.66s vs. 7.74s±1.60s, p<0.05), but the sports game group took significantly less time for continuous jumping test after intervention than the gymnastics group (5.78s±0.99s vs. 7.74s±1.60s, p<0.05). **CONCLUSION:** compared with children's basic gymnastics, the developed sports game programs are more targeted to the development of children's physical coordination and lower limb strength, therefore more effective for that purpose.

**ACUTE EFFECTS OF EXERGAMING ON URBAN
 MIDDLE SCHOOL CHILDREN'S AFFECTION BETWEEN
 SMALL-GROUP AND WHOLE-CLASS SETTINGS**

Wenxi Liu¹, Daniel J. McDonough¹, Xiwen Su¹, Kyota Takami², Zhan Gao, FACSM¹. ¹University of Minnesota Twin Cities, Minneapolis, MN. ²Hosei University, Tokyo, Japan. (Sponsor: Zhan Gao, FACSM)

Email: liux4443@umn.edu
 (No relevant relationships reported)

PURPOSE: With the goal of developing effective exergaming programs at school sites, the present study investigated the differences in urban middle school children's situational feeling states between small-group and whole-class settings. **METHODS:** Forty-seven participants (25 females; M_{BMI} = 24.3 kg/m², SD = 3.1) completed two separate 15-minute exergaming sessions on the same day: (1) Xbox One Kinect Just Dance in a small-group (n = 3-4) setting; and (2) Xbox One Kinect Just Dance in a whole-class (n = 23-24) setting. Participants' affection and emotional states were measured by the established Exercise-Induced Feeling Inventory (EFI) and Subjective Exercise Experience Scale (SEES). The 15-item EPI (5-point Likert scale ranged 0-4) included four constructs: positive affect, negative affect, fatigue, and tranquility, and the 12-item SEES (7-point Likert scale ranged 1-7) with included three

constructs: positive well-being, psychological distress, and fatigue. Dependent *t*-tests were used to detect mean differences for all outcomes between the two exergaming sessions, with the significance level being set at *p* < 0.05. **RESULTS:** Dependent *t*-test indicated significant differences on children's negative affect between two sessions (*t* = -1.77, *p* < 0.05, Cohen's *d* = 0.32). The lower mean score referred to less feeling of negative affect. Participants in small-group exergaming session (M = 0.20, SD = 0.44) experienced less negative affect in comparison to the whole-class session (M = 0.43, SD = 0.95). However, there was no significant difference in other feeling outcomes between two sessions. **CONCLUSIONS:** Findings indicated urban middle school children playing exergaming in small-group setting may experience fewer negative feelings such as crummy, discouraged, and miserable compared to the whole-class setting. Notably, there was no significant differences for other outcomes between two sessions. Future longitudinal studies are needed to examine long-term affection and emotional effects of exergaming across various settings.

**The Relationship Between Physical Activity And
 Inflammatory Markers In Youth With Overweight/
 obesity**

Justin B. Moore, FACSM¹, M. Rosa Bernal-López², Joseph A. Skelton¹, Andrew M. South¹, Antonio Vargas-Candela², Ricardo Gómez-Huelgas³, Javier Benítez-Porres⁴. ¹Wake Forest School of Medicine, Winston-Salem, NC. ²University Hospital of Málaga, Málaga, Spain. ³Carlos III Health Institute, Madrid, Spain. ⁴University of Málaga, Málaga, Spain.
 Email: jusmoore@wakehealth.edu
 (No relevant relationships reported)

While physical activity is known to have beneficial effects in youth, little is known about the mechanisms responsible for these effects, including how it affects inflammatory markers among youth. This is especially true in youth with overweight or obesity. Furthermore, it has not been definitively established that changes in physical activity can elicit changes in inflammatory markers among youth with overweight and obesity. **PURPOSE:** To determine the effect of a one-year lifestyle intervention on markers of inflammation in youth with overweight or obesity. **METHODS:** Eighty-three children (mean age 8.7 yrs ±1.2, 53% male, 46% with overweight, 53% with obesity) participating in a longitudinal intervention to increase physical activity and improve diet, provided data on physical activity (via accelerometer), body composition (via DXA), and fasting inflammatory markers (adiponectin, TNF-α, resistin, IL-6). *T*-tests were conducted to examine changes over time, and linear regression analyses were employed to assess the influence of changes over time [moderate-to-vigorous physical activity (MVPA), percent body fat] on year-one inflammatory marker values while controlling for baseline levels. **RESULTS:** Our results indicated significant decreases (all *p* < .001) at year-one from baseline in adiponectin (10.1 μg/mL to 6.6 μg/mL), TNF-α (22.1 pg/mL to 4.4 pg/mL), IL-6 (18.7 pg/mL to 10.7 pg/mL), while resistin increased significantly (3.7 ng/mL to 6.8 ng/mL). Changes in percent body fat did not significantly predict inflammatory markers at follow up. Increased MVPA over time predicted lower resistin levels at follow up. **CONCLUSIONS:** A physical activity intervention successfully reduced two inflammatory markers, and greater MPVA may protect against increases in resistin among youth with overweight or obesity.

 (No relevant relationships reported)

The potential of school-based interventions to positively impact young people's physical activity (PA) level is uncertain. A recent meta-analysis concluded that current school-based interventions do not positively impact young people's accelerometer assessed PA over the full day. **PURPOSE:** To investigate the effect of a school-based PA intervention on PA levels in 14-year-old adolescents. **METHODS:** In the School in Motion intervention study (ScIM), 29 secondary schools (N=2084) in Norway were cluster-randomized to the Physical active learning (PAL) group (n=10), the Don't worry-Be Happy (DWBH) group (n=10) or the control group (n=9). The target dose was 120 min of additional PA per week in both intervention groups. PA was assessed by ActiGraph accelerometers at baseline (spring 2017) and after one year (spring 2018). We used a linear mixed model with the means as a function of time and group-by-time interaction, with schools as random effects. **RESULTS:** No intervention effect

was observed on the students' PA level during the full day, however, an intervention effect was observed during school hours. Girls in the PAL-group, had a mean change in PA level during the intervention period that was 92 counts per minute (cpm) (95% CI: 52; 133, $p < 0.001$) higher than the control group. Girls in the PAL-group increased time spent in moderate-to-vigorous intensity physical activity (MVPA) with 6.3 min/day (95% CI: 3.8; 8.8, $p < 0.001$) more than the controls, and reduced time spent sedentary with 7.3 min/day (95% CI: -11.8; -2.8, $p = 0.001$). Boys in the PAL-group increased their mean PA-level with 77 cpm (95% CI: 19; 134, $p = 0.009$) and time spent in MVPA with 5.1 min/d (95% CI: 1.6; 8.6, $p = 0.005$) more than control boys. In the DWBH-group, no intervention effect was observed on mean PA level or time spent in MVPA, however, the DWBH-group increased their sedentary time during school hours more than their counterparts in the control group. **CONCLUSIONS:** We found no effect of a nine-months PA-intervention on 14-year-olds PA level over the full day. However, we found an effect on PA during school hours for adolescents in the PAL-intervention. As both intervention models were targeting the school hours in particular, the results might indicate that future interventions need to target after school hours to increase adolescents' PA level over the full day.

Association Between Birth Weight, Physical Activity, Sedentary Time And Body Fat In 11-13-year-old Hispanic Children
Jose A. Martínez-Rodríguez¹, Annette Jiménez¹, Mercedes Rivera¹, Ivys Figueroa², Maribel Campos³, Farah A. Ramírez-Marrero, FACSM¹. ¹University of Puerto Rico, Rio Piedras Campus, San Juan, Puerto Rico. ²University of Puerto Rico, Mayaguez Campus, Mayaguez, Puerto Rico. ³University of Puerto Rico, Medical Science Campus, San Juan, Puerto Rico. Email: martinezexercisephysiology@gmail.com
(No relevant relationships reported)

Birth weight and gestational age are early life factors linked to health characteristics during childhood and adolescence, such as obesity, physical activity (PA), sedentary time (ST). It has been suggested that birth weight is not as important as PA in the prediction of childhood obesity. However, these associations have been inconsistent across different studies, and suggestions of potential population specific differences have been proposed. **PURPOSE:** To describe and compare birth weight, gestational age, percent body fat (% fat), PA, and ST in a group of 11-13-year-old Hispanic children in Puerto Rico; and evaluate associations between these variables. **METHODS:** Ninety-six children (boys=55, girls=41) volunteered to complete anthropometric measurements (height, sitting height, weight, % fat, and arm and waist circumferences), accelerometer-based PA and ST, and a nutrition and quality of life questionnaire. Also, parents completed a sociodemographic and family health questionnaire that included the children's birth weight and gestational age. Independent t-test and correlation analyses were conducted to detect sex differences, and determine associations between variables. **RESULTS:** Mean birth weight (7.0±1.4 lbs) and gestational age (37.5±3.8 weeks) were not different between sex ($P > 0.05$), and fell within the normal range for growth standard. However, compared with boys, girls had higher % fat (17.2±1.0 vs. 28.0±1.1 %, $P < 0.0001$), lower moderate to vigorous PA (264.2±22.7 vs. 132.6±14.9 min/week, $P < 0.0001$), and higher ST (9.9±0.2 vs. 10.9±0.3 hrs/day, $P = 0.001$). No association between gestational age, % fat, PA and ST was observed. Those with higher birth weight had higher ST ($\rho = 0.22$, $P = 0.04$), but PA and % fat were not associated with birth weight. Those with higher PA and lower ST had lower % fat ($\rho = -0.34$, $P = 0.001$; $\rho = 0.24$, $P = 0.02$; respectively). **CONCLUSIONS:** These preliminary observations suggest that body fatness is not influenced by birth weight (a biological factor) but by PA and ST (behavioral factors) in our Hispanic youth participants. Supported by UPRRP/DEGI and Puerto Rico Health Department.

Association Between Physical Activity, Sedentary Time, And BMI Percentile Among Hispanic Pre-school Children
Emmanuel Hernandez-Torres, Anthony Melendez-Nieves, Luis Estrada-Oliver, Farah A. Ramirez-Marrero, FACSM. University of Puerto Rico, Rio Piedras, Puerto Rico. Email: emmanuel.hernandez3@upr.edu
(No relevant relationships reported)

For healthy growth and development, physical activity (PA) guidelines for preschool-aged children suggest at least 3 hours/day of combined structured and unstructured PA. Prevention of childhood overweight and obesity is another health priority in this population. Among 1-6-year-old Hispanic children in Puerto Rico, the prevalence

of overweight and obesity is approximately 60%. However, the association between obesity and accelerometer-based PA and sedentary time (ST) in this population have not been previously documented. **PURPOSE:** To describe PA and ST, and test the association between obesity and PA, and between obesity and ST in Hispanic pre-school children. **METHODS:** A group of 25 children (Boys = 10, Girls = 15, aged 3 to 5 years old) attending a pre-school at the University of Puerto Rico (UPR) and their parents volunteered to participate. Children's measures of height and weight, and 7-day waist-worn accelerometer data were obtained. Parents completed a socio-demographic, and family health and home environment questionnaire. Mann-Whitney U test, and Spearman correlation analyses conducted to test for sex differences and associations between variables. **RESULTS:** Light PA (1.6±0.4 hr/day), moderate PA (0.9±0.2 hr/day), vigorous PA (0.2±0.1 hr/day), ST (11.3±0.7 hr/day), and BMI percentile (63.8±30.6) were not different between boys and girls. Overweight (13%) and obesity (22%) was lower in our children participants compared to previous reports in pre-school aged Hispanic children. A significant and inverse correlation between BMI percentile and vigorous PA ($\rho = -0.46$, $P = 0.04$), and BMI percentile and number of household TV sets ($\rho = -0.55$, $P = 0.008$) was observed. **CONCLUSION:** Combining light, moderate and vigorous PA/day (2.7 hr/day); pre-school children in this study approached PA guidelines. Nonetheless, ST was high. Our results also show that those who engage in more vigorous PA have lower BMI percentile, suggesting that PA intensity might be relevant for obesity prevention in this young age group. The inverse association between number of TV sets per household and BMI percentile was unexpected; thus, requiring further analyses.

The Comparison Of Children Physical Activity Time In Different Parent Income Level
JiaChuan Xue¹, Gang He². ¹National Olympic Sports Center, Beijing, China. ²Capital University of Physical Education and Sports, Beijing, China.
(No relevant relationships reported)

There are enough researches that can prove the importance of physical activity for children's health. It's necessary to keep enough physical activity time during children's growth and development of their bodies. There are already have some researches about parent income and children's physical activity time, but those researches are all in developed countries and no studies in a developing country, such as China. **PURPOSE:** By comparing the physical activity time of children with the different parent income level and show the income level impact on children's physical activity time. **METHODS:** There are four schools selected in this study and every two schools from urban and suburbs areas in Beijing. We used the CLASS questionnaire (Children Leisure Activities Study Survey) to acquire the data about parent income (yuan/per month) and the time of children's physical activity (mins). All total of 408 students (boys=217, age=10.78±0.93yrs) and 384 parents (male=198, age=39.65±5.62yrs) are involved in this study. We divide the parent income into four levels: The low-income (0-5000yuan/per month), the middle-income (5000-10000yuan/per month), the high-income (10000-15000yuan/per month) and the highest-income (over 15000yuan/per month). The data were analyzed using one-way ANOVA. **RESULTS:** By comparing the children physical activity time in different parent income levels, with middle-income and low-income (146.43±92.94mins vs. 116.60±56.57mins, $P < 0.05$); With middle-income and high-income (146.43±92.94mins vs. 112.11±61.48mins, $P < 0.05$); With middle-income and highest-income (146.43±92.94mins vs. 105.83±62.50mins, $P < 0.05$). **CONCLUSIONS:** Parent income may have an impact on children physical activity time, the children which their parent income at a middle level have the most physical activity time. This study was conducted in a developing country and the result may differ from the developed countries. In the future, the studies should consider more factors that may impact the children's physical activity time.

2153 Board #72 May 28 2:00 PM - 3:30 PM
Associations Between Bedroom Television And Child Versus Parent-reports Of Youth Screen Time And Sleep Duration
Morgan T. Lavender¹, Joey A. Lee¹, Kelly R. Laurson². ¹University of Colorado Colorado Springs, Colorado Springs, CO. ²Illinois State University, Normal, IL. Email: mlavende@uccs.edu
(No relevant relationships reported)

INTRODUCTION: Child self-report and parent proxy-report are frequently used for assessing youth sleep duration (SLP) and screen time (ST) behaviors; however, discrepancies in the reporting of youth SLP and ST between children and parents are not well understood. **PURPOSE:** The purpose of this study was to examine if family ST rules and child bedroom televisions (BTV) were associated with discrepancies between child and parent reports of youth SLP and ST behaviors.

METHODS: Children aged 8-11 self-reported their SLP and ST behaviors, if they had a BTV, and demographic information. Parents reported information about their child's SLP and ST behaviors, family ST rules, and family characteristics (i.e. income, marital status, etc.). The prevalence of parents reporting less healthy, similar, or healthier behaviors compared to child-reports was calculated. Separate linear regression models examined if BTV and family ST rules were predictive of the discrepancies in the reporting of youth's SLP and ST between parents and children.

RESULTS: Parents reported healthier child behaviors (less screen time and more sleep) compared to child reports. Linear regression models identified child BTV as a significant predictor of discrepancies in child-parent reporting for both, SLP and ST ($p=.01$ and $p=.03$, respectively), but not family ST rules (both $p < .05$)

CONCLUSIONS: The presence of a child BTV contributes to discrepancies in child and parent reporting of youth's SLP and ST behaviors. Future work evaluating youth SLP and ST behaviors using survey tools and national data collection protocols should capture information about the presence of a child BTV.

Impact Of Situational Games Intervention On Fitness Outcomes Among 6-7 Years Old Chinese Children

Jie Zhuang¹, JunYu Wang¹, Jun Wu², XinZhao Cao¹, Yong Gao³.
¹Shanghai University of Sport, Shanghai, China. ²Shanghai Liuyi elementary school, Shanghai, China. ³Boise State University, Boise, ID.
 Email: zhuangjiesh@163.com
 (No relevant relationships reported)

PURPOSE: To examine the impact of a 10-week situational games intervention on aerobic fitness, muscular strength and speed among 6-7 years old Chinese children. **METHODS:** A total of 128 6-7 years old Chinese children were randomly divided into intervention group (IG; 31 boys, 30 girls) and control group (CG; 31 boys, 36 girls). The IG received ten-week situational games (SG) lessons (35 mins per lesson, twice a week), including acting as a main character in the movie 'zootopia', offending and defending in ball games, and exploring in the forest, while CG took conventional PE lessons (35 mins per lesson, twice a week). Participants took 20-m shuttle run (20-m SRT), grip, vertical jump (for muscular strength) and 50-meter dash (for speed) tests before and after intervention. VO2max was estimated from 20-m SRT using Leger's equation. Mixed model Repeated Measures ANOVAs were conducted to determine differences in fitness variables from baseline to post-intervention across intervention groups.

RESULTS: The performance of 20-m SRT (laps), Grip(kg), Vertical jump (cm) and 50-meter dash(s) were significantly improved among IG while no change among CG after intervention in boys. There was also a significant group-by-time interaction was observed for Grip(kg), Vertical jump (cm) and 50-meter dash(s) in girls, no difference between IG and CG at baseline, but vertical jump performance was significantly improved among IG while no change among CG after intervention. Although 20-m SRT scores of both IG and CG participants increased from baseline to after intervention, there was no group difference in the improvement, $p < 0.05$. (Table 1)

CONCLUSIONS: Although both conventional PE and SG specific lessons can increase muscular strength and speed, 10-week SG training also effectively improves aerobic fitness among 6-7 years old Chinese children. There was different improvement between genders.

Table1 Comparison between IG and CG on Fitness

		CG Boys(n=31)	IG Boys(n=31)	CG Girls(n=36)	IG Girls(n=31)

Genu Valgus Association Between Physical Activity Level Anthropometry And Sedentary Behavior In Schoolchildren From Ilhabela

Pedro Paulo Oliveira Moda. *celafiscs, São Caetano do Sul, Brazil.*
 Email: pedro.paulooliveira@hotmail.com
 (No relevant relationships reported)

Objective: To analyze the relationship between the valgus knee and the level of physical activity and anthropometry in students of both sexes. **Methods:** In this cross-sectional study, 96 students with an average of 9.75 ± 0.78 years-old, 56 female students ($X \ 9.78 \pm 0.78$ years) and 40 males ($X \ 9.7 \pm 0.78$ years) aged 9 to 11 years, residing in Ilhabela, São Paulo. The genu valgus was evaluated using the goniometer, classifying the intermalleolar distance (cm) as mild, moderate and severe. The level of physical activity was evaluated by accelerometer (ActiGraph GT3X-BT, Freedson P.S) given in counts per week, being classified into physical activity: mild, moderate, moderate to vigorous, vigorous and sedentary time. The anthropometric variables included: body weight (kg), height (cm), BMI (kg / m^2), mean skinfold thickness (mm), femur diameter (cm), and waist circumference (cm), according to CELAFISCS standardization. **Statistical Analysis:** It was used the Person correlation, a software SPSS 20.0, adopting as significance level a $p < .05$. **Results:** Of the 96 students, 53% presented mild valgus, 21% with moderate valgus, and 22% with severe valgus, with positive and significant associations ($p < .05$). In both sexes, there was no correlation between mild, moderate, moderate to vigorous, vigorous physical activity and sitting time. In girls there was a positive, moderate and significant correlation between genu valgus, weight, height and waist circumference and skinfolds. In boys there was a positive, weak, and significant correlation between genu valgus and femur diameter. **Conclusion:**, it seems that the genu valgus was not associated with physical activity levels and sitting time, but shows that the greater the valgus, the greater the sedentary time. It was also observed an association with anthropometry in males, with femur diameter and in the female with the weight and waist and hip circumference.

Variables		Male Genu valgus		Female Genu valgus	
		r	p	r	p
LIGHT PHYSICAL ACTIVITY	(counts/sem)	-0,06	0,69	0,19	0,14

PHYSICAL ACTIVITY LEVEL SEDENTARY BEHAVIOR AND SLEEP TIME ASSOCIATED TO BODY COMPOSITION IN ILHABELA SCHOOLCHILDREN

Anderson Bastos Lopes, Luis Carlos de Oliveira, João Pedro da Siva Junior, Maurício dos Santos, Diana Carolina Gonzalez Beltran, Victor Keihan Rodrigues Matsudo. *CELAFISCS, São Caetano do Sul, Brazil.*
 (No relevant relationships reported)

Purpose: To associate the physical activity level, sedentary behavior, and sleep time with the body composition of students. **Methods:** The study is part of the Ilhabela Mixed-Longitudinal Growth and Development Project. A convenience sample consisted of 97 schoolchildren, 50 boys, and 47 girls, 9 to 11 years-old ($9.8 \pm .7$) with at least one complete evaluation in the analyzed period (2015 and 2019), all of them at pre-pubertal sexual maturation. The variables analyzed were: body weight (kg); body mass index BMI (kg/m^2); average of 3 skinfolds: triceps, subscapular, and suprailiac, adiposity (mm); and waist-to-hip ratio WHR (cm). Physical activity level, sedentary

THURSDAY, MAY 28, 2020

behavior, and sleep time were measured by accelerometer (ActiGraph GT3X, analyzed with Freedson 1998) given in counts per minute. Data normality was measured by Kolmogorov-Smirnov, and a Spearman rho correlation was used to determine the associations among variables. Level of significance adopted was $p < .05$. The software used was SPSS 20.0. **Results:** In boys, light physical activity presented a significant low to moderate correlations with BMI ($r = .29$), adiposity ($r = .29$), WHR ($r = .39$). A correlation of ($r = .39$) was observed between sedentary time, and WHR. Among girls, sedentary time correlated significantly with body weight ($r = .41$), BMI ($r = .29$) adiposity ($r = .47$). Moderate to vigorous PA presented an inverse, significant, and moderate correlations with body weight ($r = .39$), and adiposity ($r = .40$). **Conclusion:** Present data suggest a significant association among light PA (in boys) and moderate/vigorous PA (in girls), and body composition, while sedentary time showed a significant association with body weight, BMI, and adiposity (in girls), and with WHR (in boys).

Table: Association between physical activity level, sedentary behavior and sleep time to body composition in students from Ilhabela

	Boys				Girls			
	Weight (kg)	BMI (kg/m ²)	Adiposity (mm)	WHR	Weight (kg)	BMI (kg/m ²)	Adiposity (mm)	WHR
Sedentary Time	.04	-.06	.01	.39*	.41*	.29*	.47*	.32
Light PA	-.24	-.29*	-.29*	.39*	-.04	.15	.03	-.06
Moderate/vigorous PA	-.20	-.11	-.15	.16	-.39*	-.11	-.40*	-.01
Sleep time (hours/day)	.14	.16	.05	-.19	-.07	-.06	-.13	-.15

Body Weight (Weight) Light physical activity level (Light PA) Moderate to vigorous physical activity level (Moderate/vigorous PA) * $p < .05$.

Dissemination Of Motivational Interviewing Training: Use In Extension Outreach And School Health Programming

Kathryn J. DeShaw¹, Laura D. Ellingson², Gabriella M. McLoughlin³, Gregory J. Welk, FACSM³. ¹Loras College, Dubuque, IA. ²Western Oregon University, Monmouth, OR. ³Iowa State University, Ames, IA. (Sponsor: Gregory J. Welk, FACSM)
 (No relevant relationships reported)

PURPOSE: Motivational interviewing (MI) is a popular conversational strategy used to evoke intrinsic motivation for behavior change. Although a number of training programs have been described to build MI skills, there are few that evaluate the fidelity of training. The present study evaluated MI fidelity following a brief online training. **METHODS:** This study was conducted as an ancillary component of a school wellness training initiative (SWITCH) that focused on building capacity for schools to plan and lead school wellness programming. A quasi-experimental design was used to evaluate the impact of brief MI training on a sample of 16 extension field specialists (EFS) that facilitated the SWITCH implementation process. EFS were provided guidelines and suggestions for using MI to elicit change talk and promote goal setting by school leaders. A subsample of 8 EFS voluntarily agreed to participate in supplemental MI training prior to interacting with the schools. All EFS recorded phone calls with the schools as part of the standard practice in the SWITCH project, and a trained assistant blinded from group allocation coded them for MI proficiency levels using the Motivational Interviewing Treatment Integrity Coding Manual 4.2.1. **RESULTS:** A one-way ANOVA followed by Bonferroni post-hoc corrections were conducted to examine differences in MI techniques between trained and untrained EFS. No statistically significant results were found. However, differences between groups for technical global scores ($F(1, 14) = 8.9, p = 0.05, d = 1.5$) and reflection-to-question ratios ($F(1, 14) = 5.3, p = 0.19, d = 1.15$) were approaching statistical significance with large effect sizes. Relational global components ($d = 0.76$) and total adherence ($d = 0.38$) demonstrated moderate group differences. **CONCLUSIONS:** This study indicates that a brief MI training protocol is effective for teaching the spirit and relational components of MI. Although proficiency levels were not achieved by the majority of EFS, trained individuals were better at using technical and relational aspects of MI than untrained individuals. Future work should focus on ways to enhance skill acquisition with this type of distributed online training model as well as testing applications with other professionals and diverse settings.

2158 Board #77 May 28 2:00 PM - 3:30 PM
Comparison Of Anthropometric Methods And Physical Activity In Preschoolers

Connie L. Tompkins, Erin K. Shoulberg, Lori E. Meyer, Caroline P. Martin, Marissa Dennis, Allison Krasner, Hannah Cook, Betsy Hoza. University of Vermont, Burlington, VT.
 Email: Connie.Tompkins@med.uvm.edu
 (No relevant relationships reported)

Previous work reports a counterintuitive finding that preschoolers categorized as overweight or obese engage in more physical activity (PA) than their healthy weight peers. The majority of studies with preschoolers however, used age- and sex-specific body mass index (BMI) percentiles to classify children according to their weight status. However, BMI may underestimate obesity prevalence. More recently, there has been an emphasis on anthropometric alternatives to BMI such as waist-to-height ratio. Waist circumference (WC) to height ratio (WC/HT) is relatively independent of gender, age, and race and may be more sensitive than BMI to identify those with central obesity, a cardiometabolic risk factor.

PURPOSE: Examine 1) the overlap of risk based on BMI and WC/HT and 2) the associations between preschoolers' PA and both BMI and WC/HT **METHODS:** Weight, height, and WC were obtained by trained study staff and PA was objectively measured by accelerometry during the school day for up to 10 days. BMI was calculated as body weight divided by height squared (kg/m²). Weight status was determined using age- and sex-specific Centers for Disease Control (CDC) BMI percentiles. Two BMI percentile overweight/obese risk categories were created based on CDC categories (not at risk: $< 85^{th}$; at risk: $\geq 85^{th}$). Two central obesity risk categories were created for WC/HT (not at risk: < 0.5 ; at risk: ≥ 0.5). A total of 69 children ($M_{age} = 3.95 \pm 0.6, 34$ males, 35 females) with ≥ 3 days of valid accelerometer data were included in analyses. Percentage of time spent in light, moderate-to-vigorous (MVPA) and total PA (light + MVPA) were calculated using the child's total wear time as the individual divisor. Significance was set at $p < 0.05$.

RESULTS: When comparing BMI and WC/HT risk categories, only 21 children (30%) were considered at risk using BMI whereas 40 (58%) were considered at risk using WC/HT. Significant, positive associations were observed between BMI percentile and light ($r = 0.27$), MVPA ($r = 0.25$) and total PA ($r = 0.27$); no significant associations were observed between WC/HT and PA.

CONCLUSIONS: More preschoolers were identified at risk using WC/HT as compared to BMI. Moreover, higher levels of PA were only linked with risk based on BMI, not WC/HT. Future work with preschoolers should explore a variety of methods for measuring risk for obesity and PA.

Can We Play Outside? Social-emotional Learning And Preschooler Physical Activity

Marcia Rosiek¹, Benedict P. Dyson², Erin J. Reifsteck², Diane Gill, FACSM². ¹Coastal Carolina University, Conway, SC. ²UNC at Greensboro, Greensboro, NC. (Sponsor: Diane Gill, FACSM)
 Email: marosiek@uncg.edu
 (No relevant relationships reported)

Can we Play Outside? Social-Emotional Learning and Preschooler Physical Activity Marcia A. Rosiek, Benedict P. Dyson, Erin J. Reifsteck, & Diane L. Gill, FACSM Coastal Carolina University & UNC at Greensboro Despite the benefits of physical activity (PA) for their development, preschoolers (age 3-5) do not meet recommendations and spend the majority of their day indoors engaged in sedentary behaviors (Pate et al., 2008). Outdoor environments promote PA (Cerrin et al., 2016), and active play is considered important for social and emotional learning (SEL), which involves self-regulatory and problem-solving skills, making good decisions, and developing positive relationships. Early childhood SEL is associated with school readiness and academic achievement (Denham & Brown, 2010). Research on the role of outdoor play for SEL in early childhood development is limited. **PURPOSE:** To identify and describe PA and SEL behaviors practiced by preschoolers in the outdoor environment. **METHODS:** This case study used mixed methods to identify and describe SEL and PA behaviors in preschoolers (ages 3-5) at an early childhood education center (ECEC). Participants included 28 children, two teachers and the ECEC director. PA accelerometry data, daily observations, and teacher interviews were collected over 4 weeks. Inductive analysis and constant comparison were used to analyze the qualitative data (Miles, Huberman, & Saldana, 2014). **RESULTS:** Accelerometry data indicate that preschoolers were engaged in sedentary behavior 46.53%, MVPA 30.81%, and light activity 21.19% of the time when outdoors; on average, preschoolers were active for 29.34 minutes during an average 56.45-minute outdoor period. Qualitative data uncovered three themes: 1) the outdoor environment provides opportunities to practice SEL, 2) social interaction

during outdoor play promotes SEL, and 3) teachers support SEL during outdoor play.

CONCLUSION: The outdoor environment promotes PA through multiple forms of active play, providing an ideal setting for preschoolers to practice SEL in their preferred environment.

The Ministry of Education of China has carried out spot check and review of the test data of "National Standards for Students' Physical Health" for many years, however, the effect of the investigation and the changes of students' physical health are unclear. **PURPOSE:** To analyze the changing characteristics of students' physical health from 2016 to 2018.

METHODS: We used 2016-2018 National Students Physical Health Sample Survey data for students from grade one in primary school to senior student (N= 221,053; 220330; 227,160). National norm reference standard was adopted to evaluate students' test scores of various items in body shape, function, constitution, and the total score was calculated after the scores of all the items were weighted. According to the total score, students were evaluated by four grades (excellent, good, pass and fail), BMI was used for obesity evaluation, which was divided into obesity, overweight, normal and low weight.

RESULTS: (1) From 2016 to 2018, the overall failure rate decreased from 12.0% to 11.3%, the favorable rate increased from 21.9% to 24.1%, and the excellent rate rose from 4.6% to 6.2% year by year. (2) The average proportion of primary students who reached the standard within three years was 93.0%, middle school students was 88.0%, high school students was 89.1% and college students was 73.7%. (3) The average proportion of overweight and obese students in China in the past three years is 21.6%, among which the average proportion of overweight was 13% and the obese was 8.6%. As a result, more than one fifth of the students' BMI were overweight or obese. In addition, from 2016 to 2018, the proportion of students who are obese was 7.9%, 8.9% and 9.0%, and the proportion of students who are overweight was 12.3%, 13.4% and 13.4%, respectively. The proportion of students who are overweight and obese increased year by year.

CONCLUSIONS: In the past three years, students' physical health has been gradually improved. The overall level of students' physical health decreased with the increase of learning period. The proportion of overweight and obesity in Chinese students is on the rise year by year. **Acknowledgment:** This study was supported by special project and laboratory of Ministry of Education in BSU.

Moderate-to-vigorous Physical Activity Trajectories During Adolescence And Young Adulthood Predict Adiposity In Young Adulthood: The Iowa Bone Development Study

Minsuk Oh, Dong Zhang, Kathleen Janz, FACSM, Elena Letuchy, Steven Levy. *University of Iowa, Iowa City, IA.*

Email: minsoh@uiowa.edu

(No relevant relationships reported)

Purpose: The purpose of this study was to examine the association between MVPA patterns throughout adolescence described by trajectory models and adiposity indicators (i.e., fat mass index (FMI) and visceral adipose tissue (VAT) mass index) at young adults aged 23 years.

Methods: Study participants aged 15, 17, 19, 21, and 23 years from the Iowa Bone Development Study were included. Accelerometry-measured MVPA (min/day), and FMI (kg/m²) and VAT mass index (g/m²) derived from dual-energy X-ray absorptiometry scans were collected at each age. FMI and VAT mass index as outcome variables were converted to z-scores. Group-based trajectory analyses (N = 297; Females = 168; 94% white) classified the MVPA patterns into sub-groups (group 1: 'moderately active with decreasing MVPA' vs. group 2: 'consistently active and maintaining high MVPA') and sex (females vs. males).

Results: A trajectory model identified that MVPA levels declined over time in both males and females, and the decline was more remarkable in females. The multivariable linear regression analyses showed that trajectory group (either group 1 or 2) was associated with FMI ($\beta = -.44, p = .042, R^2 = .64$) and VAT mass index ($\beta = -.52, p = .48, R^2 = .47$) z-scores.

Conclusion: This study concluded that individuals who are consistently active with maintaining their MVPA during adolescence up until early young adulthood are less

likely to accumulate total body and visceral adiposities in young adulthood. This study suggests that adopting a consistently active lifestyle throughout adolescence to achieve healthy body compositions in emerging adulthood.

The Association Of Fitness With Middle-distance Running Performance In Chinese Boys

Zheng Zhu¹, Xiang Fan², Zhen-Bo Cao¹. ¹Shanghai University of Sport, Shanghai, China. ²Shanghai Jiao Tong University, Shanghai, China.

(No relevant relationships reported)

There has been a paucity of evidence pertaining to the discussion whether the effect of fitness on CRF is independent of physical activity (PA).

PURPOSE: The objective of this study was to examine the association of fitness with middle-distance running performance (MDRP) in Chinese boys.

METHODS: A cross-sectional study was conducted among 180 (8th grade) boys recruited from 3 junior middle schools in Shanghai, China. Participants completed height and weight measurement, and MDRP (1000 m running). PA and sedentary behavior (SB) were measured in 7 consecutive days by accelerometers. Based on the criteria set by the Working Group on Obesity in China, the participants were categorized into either overweight and obese or normal weight according to the body mass index (BMI). Likewise, MDRP was categorized into pass or no pass by using the 2014 revised Chinese National Student Physical Fitness Standard. Independent *t* test was employed to compare the difference of the time to complete MDRP between

overweight and obese boys and normal weight boys. Correlation coefficients were computed to examine the relationship between BMI and the time to complete MDRP. The association of fatness and MDRP were examined, through multiple logistic regressions, after controlling for age and SB, light physical activity (LPA), moderate and vigorous physical activity (MVPA).

Results: 89 boys (age: 13.4±0.5 years, weight:59.3±12.7 kg, height:166.5±6.2 cm, BMI: 21.4±4.3 kg/m²) provided the valid accelerometer data (defined as ≥ 2 days, ≥10 h/day) and were included in the study. The time to complete MDRP of overweight and obese boys was significant longer than normal weight boys (320.1±42.1 s vs 270.8±35.3 s, P<0.001). BMI was significantly positively correlated with the time to complete MDRP (r=0.581, P<0.001). The overweight and obese boys were more likely to not pass the MDRP compared with the normal weight boys (adjusted odds ratio = 4.64; 95% confidence interval: 1.74-12.4), after adjusting age, SB, LPA, MVPA.

CONCLUSION: The results uncovered that boys' BMI was negatively correlated with MDRP. More importantly, compared with normal weight boys, overweight and obese boys had a higher risk to not pass the MDRP, independent of PA.

2165 Board #84 May 28 2:00 PM - 3:30 PM

COORDINATION IS NOT RELATED TO A PARENT'S PERCEPTION OF ABILITY OR SUPPORT FOR PHYSICAL ACTIVITY

Martha Rose Koenig, Kyle L. Sorenson, Mary C. Stenson.
College of St Benedict and St. John's University, St. Joseph, MN.
(No relevant relationships reported)

PURPOSE: To examine the relationships between parental support for children's physical activity and perceptions of the child's athletic competence with their child's gross motor development.

METHODS: 28 parents (36 + 11 yrs) completed a survey to assess indicators of support for their child's physical activity and child's athletic competence in relation to the child's peers. 41 children (20 males, 20 females, 1 unreported gender, 6.72 + 3.13 yrs, BMI 16.43 + 2.85) completed the Test of Gross Motor Development (TGMD2) which was converted to an age adjusted percentile score for both locomotor ability and object control. Bivariate correlations and independent sample t-tests were performed to identify relationships between variables and child gender differences.

RESULTS: No relationship was found between parental perception of coordination and child's object control skills (r = -0.001) or locomotor ability (r = 0.069). Parental support for physical activity was not related to the child's object control (r = 0.016) or locomotor ability (r = -0.118). A moderate positive relationship exists between parental perceptions of boys coordination and their object control scores (r = 0.414) and a moderate negative relationship exists for girls (r = -0.497). There were no differences between boys and girls for object control scores (boys: 61.65 + 24.57; girls: 57.95 + 21.75; t = 0.504, df = 38, p = 0.617), locomotor ability (boys: 74.75 + 22.31; girls: 75.75 + 20.51; t = -0.148, df = 38, p = 0.883) or parental support (boys: 8.68 + 3.45, girls: 9.44 + 3.65; t = -0.651, df = 35, p = 0.519).

CONCLUSIONS: Parental support for physical activity and how parents perceive their child's ability are not reliable indicators of their child's demonstrated motor ability. This may be especially true for young girls whose parents perceive them as less coordinated than they are.

Psychosocial Correlates Of Physical Activity In Children And Adolescents: A Meta-analysis

Daniel Chi Shing Yeung, Aurelian Bidulescu. *Indiana University Bloomington, Bloomington, IN.* (Sponsor: Stanley Sai-Chuen Hui, FACSM)

Email: danyeung@indiana.edu

(No relevant relationships reported)

PURPOSE: This study investigated the association between physical activity (PA) and Theory of Planned Behavior (TPB, Ajzen, 1991)-based variables among children and adolescents.

METHODS: We evaluated the association between PA and TPB-based variables (intention, attitude, subjective norms, and perceived behavioral control / self-efficacy to engage in PA) among children and adolescents, and the moderation effects of geographical region of study between PA and TPB-based variables. A total of 36 articles met the inclusion criteria and were meta-analyzed. **RESULTS:** Intention

significantly correlated with and had a medium effect on PA in children. TPB displayed a good fit in path analysis. Moderator analyses showed that subjective norms and perceived behavioral control / self-efficacy had a larger effect on children in the rest of the world, compared to their North American counterparts.

CONCLUSIONS: The results provide a summary of current scientific findings about the association between TPB-based variables and PA in children and adolescents, and support TPB as a feasible conceptual framework to study psychosocial factors that underpin PA.

Global Accelerometer-derived Physical Activity Levels From Preschoolers To Adolescents: A Meta-analysis And Meta-regression

Han Chen¹, Jiling Liu², Yang Bai³. ¹Valdosta State University, Valdosta, GA. ²Texas A&M University, College Station, TX. ³The University of Utah, Salt Lake City, UT.

Email: hanchen@valdosta.edu

(No relevant relationships reported)

PURPOSE: It is essential to document people's PA levels worldwide with accurate information. The importance needs to focus on understanding how PA pattern changes at different time periods. One of the major measurement issues of using accelerometers is the selection of cut points to determine PA intensity such as moderate to vigorous PA (MVPA). Studies calibrating accelerometers generated large variability in cut points especially for the intensity of MVPA which need to be controlled to generate more accurate and meaningful data. Thus, we systematically reviewed and meta-analyzed global MVPA change across different age groups (preschool ages to adolescence) using data derived from accelerometer while accounting for two most popular cut points [i.e., Freedson, 1998; Everson, 2008] and continents.

METHODS: We searched major data base from inception until Aug, 2019 including cross sectional or longitudinal PA tracking studies in which daily MVPA were measured by accelerometer and determined by the two aforementioned cut points for preschoolers, children, and adolescents. Random-effect models were used for meta analyses. Multiple meta regression analyses were conducted to investigate how age relates to daily MVPA from preschooler to adolescents while controlling for cut points and continents.

RESULTS: The final data includes 91 studies representing 42338 participants across six continents. Findings revealed that for the combined studies, participants accumulated 74.44 minutes of MVPA each day (95% CI = 68.86 - 80.02, p < .001). Findings from meta regression revealed that when cut points and continents were controlled, participants' daily MVPA levels tend to decrease significantly from preschool years to adolescents (β = -8.23, p < .0001, R² = 0.4), from preschool years to children (β = -11.54, p < .0001, R² = 0.39), or from children to adolescents (β = -6.83, p < .0001, R² = 0.48).

CONCLUSIONS: Globally, individuals' daily MVPA tends to decrease from a very young age after controlling for cut points and continents. These declines were more prominent from preschoolers to childhood.

A Meta-analysis Protocol Among Active Healthy Kids Report Cards' Indicators In East Asian Regions

Robin ST Ho¹, Wendy Y Huang², Stephen HS Wong, FACSM¹.

¹Chinese University of Hong Kong, Hong Kong, Hong Kong.

²Hong Kong Baptist University, Hong Kong, Hong Kong.

Email: robinho@cuhk.edu.hk

(No relevant relationships reported)

Insufficient physical activity (PA) is one of the leading risk factors for mortality. Evidence related to PA in children and youth has been assessed comprehensively in the Active Healthy Kids Report Cards worldwide. However, the association between influence indicators and behavioral indicators among Report Cards are yet to be critically appraised and synthesized using the method of meta-analysis. **PURPOSE:** We aim to perform meta-analyses for indicators in overall PA, sedentary behaviors, school, family & peers, and community & environment among East Asian regions with very high Human Development Indices.

METHODS: We conducted literature search in six international databases, including CENTRAL, MEDLINE, EMBASE, PsycINFO, Global Health, and BIOSIS. Observational studies with at least one influence indicator and one behavioral indicator will be considered eligible and data will be extracted for meta-analyses. The strength of association between influence indicators and behavioral indicators will be synthesized. The pooled effect sizes and their 95% confidence intervals for each association will be calculated. Newcastle-Ottawa Scale will be used for the risk of bias assessment among included observational studies. **RESULTS:** Twenty eligible observational studies including cohort studies and cross-sectional studies were included. From these 20 included studies, twelve, seven, and one were from Hong Kong, South Korea, and Japan respectively. Ten studies addressed behavioral indicators, e.g. the association

between screen time and obesity. The other ten studies addressed influence indicators, e.g. the association between parents' exercise frequency and the children's intention to participate in PA. **CONCLUSIONS:** Results of meta-analyses may inform better decision-making in tackling complex public health crisis created by physical inactivity and sedentary behaviors among children and youth in East Asian regions, triggering the engagement with relevant stakeholders among sectors of the community, as well as their joint cooperation in the development of a more friendly environment for children and youth to perform PA.

Accelerometer-measured Physical Activity And Sedentary Behavior In Chinese Children And Adolescents: A Meta-analysis
 Zhaohua Zhang, Hongjuan Li, Ting Zhang, Liu Zhang, Chunyan Gui. *Beijing Sport University, Beijing, China.*
 Email: 461004974@qq.com
 (No relevant relationships reported)

PURPOSE: To assess moderate-to-vigorous physical activity (MVPA) and sedentary behavior (SB) levels of Chinese children and adolescents using accelerometer and to examine the differences between different populations according to gender, age/grade, day (weekdays and weekends) and geographical region.
METHODS: Four online databases were searched for studies published from January 2009 up to February 2019 (PROSPERO2019: CRD42019129888). These studies reported accelerometer-measured daily minutes of MVPA and/or SB among Chinese children and adolescents. Random-effects meta-analysis was used to separately pool the time spent in MVPA and SB.
RESULTS: Out of 4754 records, 20 studies were considered to be suitable for inclusion in the meta-analysis. Sample sizes ranged from 96 to 2163. The meta-analysis found that Chinese children and adolescents spent 41.11 min/day, 529.83 min/day in MVPA and SB, respectively. Boys spent more time in MVPA compared with girls (boys' vs girls: 45.57 vs 36.37 min/day, $p = 0.01$). Children accumulated significantly more minutes of MVPA than adolescents (children vs adolescents: 43.37 vs 37.52 min/day, $p = 0.05$), and children spent less time in SB than adolescents (children vs adolescents: 508.79 vs 553.51 min/day, $p = 0.05$). Unlike weekdays, SB was lower on weekends (weekdays vs weekends: 530.94 vs 486.57, $p = 0.02$). There were significant differences in Children and adolescents' MVPA time in regions (Hong Kong vs North China vs South China: 60.55 vs 43.21 vs 36.49 min/day, $p < 0.001$).
CONCLUSIONS: While their SB level is high, MVPA level in Chinese children and adolescents is well below international recommendations. The analyses suggested that boys spent more time in MVPA compared to girls. The MVPA level of Children is higher than adolescents. Children and adolescents living in Hong Kong are more active than in North China and South China. SB level of children is lower than adolescents. Compared with weekdays, SB level of Chinese children and adolescents is lower on weekends.

The Effect Of Physical Exercise Intervention On Brain Development In Adolescent: A Systematic Review And Meta-analysis
 Hao Pu¹, Xiaolei Liu², Jindong Chang¹. ¹College of Physical Education Southwest University, Chongqing, China. ²High School Affiliated to Southwest University, Chongqing, China.
 Email: haopswu2018@163.com
 (No relevant relationships reported)

The relationship between physical activity (PA) and exercise with brain development in adolescents has seen a growing interest during the past two decades. Previous systematic reviews and meta-analyses have shown the effectiveness of PA interventions on improving adolescents' brain cognition. **PURPOSE:** The study aimed to assess the effect of physical activity (PA) interventions and adolescents' brain development.
METHODS: We systematically searched MEDLINE, Web of Science, and Pubmed database from their inception to June 30th, 2019. Intervention studies aimed at examining the exercise-brain interaction at a developmental age were included in this systematic review and meta-analysis. Random-effects models were used to calculate pooled effect size (ES) values and their corresponding 95% CIs. Subgroup analyses were conducted to examine the effect of participants' and PA programs' characteristics.
RESULTS: A total of 25 studies were included in this systematic review and meta-analysis. Pooled ES estimations were as follows: working memory 0.45 (95% CI = 0.28-0.61), inhibition 0.08 (95% CI = 0.02-0.14), attention 0.61 (95% CI = 0.44-0.78) and brain psychological functions 1.05 (95% CI = 0.67-1.43).
CONCLUSIONS: PA benefits several domains of working memory, inhibition, attention and brain neurophysiology functions in youth. Physical activity interventions and programs designed to increase the number of PA per day after school seems to be the most effective. The Effectiveness Of Physical Activity On Motor Skills In Children With Neurodevelopmental Disorders: A Meta-analysis
 Meiqi Zhang, John Liu. *Springfield College, Springfield, MA.*
 Email: mzhang2@springfieldcollege.edu
 (No relevant relationships reported)

Background: Researchers of epidemiological studies in recent years have witnessed the expansion of children with neurodevelopment disorders (NDDs), particularly of children with attention-deficit/hyperactivity disorder (ADHD), autism spectrum disorder (ASD), Down syndrome (DS), developmental coordination disorder (DCD), Cerebral palsy (CP). Noticeable motor deficits are among common characteristics of children with NDDs, which indicate the need for interventions to promote optimal motor and overall development. While physical activity (PA) has been widely used in the rehabilitation of children with NDDs to improve their motor performance, questions remain whether or not the beneficial effects of PA are conclusive. The purpose of this study was to conduct a systematic review and meta analysis of the studies investigating the effects of PA on motor skill performance in children with NDDs. **Methods:** Relevant articles were sourced from PubMed, the Web of Science, EBSCO, the Cochrane Library, CNKI and Wanfang data. **Results:** Twenty studies with 269 subjects met inclusion criteria for this review and were included. Compared with pre-interventions, there was a significantly improve in motor skills (Fig.1 & 2), the gross motor skills (SMD [standardized mean difference] = 0.64, 95%CI [coefficient interval]: 0.29 to 0.99), fine motor skills (SMD = 1.33, 95%CI: 0.57 to 2.09) respectively. **Conclusion:** PA could effectively improve gross and fine motor skill performance in children with NDDs. Although the findings were based on a small number of studies, the results of this meta-analysis still suggest that researchers and clinicians should consider including PA in their rehabilitation programs for children with NDDs. Future studies should clarify which type and what intensity of PA intervention might be most effective in promoting motor development based on individual children's needs and treatment characteristics.

Fig. 1 Forest plot for change in gross motor skills

Purpose: To examine the influence of prenatal exercise on maternal cardiorespiratory health and fitness during pregnancy. **Methods:** Online databases were searched up to February 25, 2019. Studies of randomized controlled trials (RCTs) were

THURSDAY, MAY 28, 2020

eligible, which contained information on the relevant population (pregnant women), intervention (subjective or objective measures of frequency, intensity, duration, volume, or type of exercise), comparator (no exercise intervention), and outcomes (maternal cardiorespiratory fitness, including VO_{2max} , submaximal VO_2 , VO_2 at anaerobic threshold, and cardiorespiratory health, including resting heart rate, resting systolic and diastolic blood pressure during pregnancy). **Results:** From 2699 unique citations, 26 RCTs (N= 2292 women) were included. "Low" to "high" certainty evidence revealed that exercise was associated with improved VO_{2max} (five RCTs, n=430; mean difference [MD]=2.77 mL/kg/min; 95% confidence interval [CI]: 0.32 to 5.21, $I^2=69\%$), reduced resting heart rate (nine RCTs, n=637; MD= -1.71 bpm; 95% CI: -3.24 to -0.19, $I^2=13\%$), resting systolic blood pressure (16 RCTs, n=1672; MD: -2.11 mmHg, 95% CI: -3.71 to -0.51, $I^2=69\%$) and diastolic blood pressure (15 RCTs, n=1624; MD: -1.77 mmHg, 95% CI: -2.90 to -0.64, $I^2=60\%$). **Conclusion:** Prenatal exercise interventions improve maternal VO_{2max} and reduce resting heart rate and blood pressure. PROSPERO registration number: CRD42019131249.

Effects Of Multidimensional Lifestyle Interventions On Children's Body Composition And Blood Pressure: A Network Meta-analysis

Xiwen Su¹, Menglu Liang², Haitao Chu¹, Zan Gao, FACSM¹.
¹University of Minnesota, Minneapolis, MN. ²Pennsylvania State University, University Park, PA. (Sponsor: Dr. Zan Gao, FACSM)
 Email: su000057@umn.edu
 (No relevant relationships reported)

PURPOSE: A variety of clinical trials with various lifestyle intervention programs are available to address pediatric obesity and chronic diseases. Yet, no known research has used network meta-analysis to synthesize the findings simultaneously. In response, this network meta-analysis aimed to compare the effectiveness of multiple lifestyle interventions on children's body composition and blood pressure changes. **METHODS:** A total of 312 published studies on lifestyle intervention programs were retrieved with 37 studies meeting the following inclusion criteria: (1) data-based articles published in English between 2009 and 2019; (2) used randomized controlled trial design; (3) subjects aged between 1 to 12 years old and did not suffer from any physical or mental illness; and (4) investigated some type of intervention on body mass index (BMI), BMI z-score (BMIz), body fat percentage, systolic blood pressure (SBP) and diastolic blood pressure (DBP) among children. Data extraction for comparisons was completed for 10 intervention categories: (1) control (T1; no intervention); (2) physical activity (PA)/exercise only (T2); (3) knowledge education in various dimensions (T3); (4) nutrition (T4); (5) environment changes (T5); (6) PA plus education (T6); (7) nutrition plus education (T7); (8) environment changes plus education (T8); (9) PA with nutrition and education (T9); and (10) PA with environment changes and education (T10). Package "pnetmeta" in R software was mainly used to carry out the analysis. **RESULTS:** Based on mean difference (MD) comparison, nutrition plus education and physical activity (PA)/exercise only appeared to be two most effective ways in reducing children's body fat percentage compared with treatments 3, 5, 6 and 10 (Effect Size(ES) = -2.33, 95%CI: (-4.17, -0.44); ES = -1.61, 95% CI: (-2.47, -0.68) respectively). For children's BMI, T9 was the most effective approach compared with seven other treatments. T2 demonstrated the best scores in both BMIz and SBP (ES = -5.57, 95%CI: (-8.37, -2.64)) in final estimation. **CONCLUSIONS:** PA intervention ranked top two of the most effective approaches among 9 types of lifestyle interventions in all 5 MD comparisons, suggesting that promoting PA participation is crucial in childhood obesity control.

Physical Activity, Sedentariness And Metabolic Risk In Portuguese Children

Thayse Natacha Gomes¹, Peter T. Katzmarzyk, FACSM², Fernanda Karina dos Santos³, Sara Pereira⁴, Michele Souza⁵, Raquel Chaves⁶, José Maia⁴. ¹Federal University of Sergipe, São Cristóvão, SE, Brazil. ²Pennington Biomedical Research Center, Baton Rouge, LA. ³Federal University of Viçosa, Viçosa, MG, Brazil. ⁴CIFID, Faculty of Sport, University of Porto, Porto, Portugal. ⁵Federal University of Santa Catarina, Florianópolis, SC, Brazil. ⁶Federal University of Technology of Paraná, Curitiba, PR, Brazil.
 Email: thayse_natacha@hotmail.com
 (No relevant relationships reported)

It has been suggested that physical activity (PA) and sedentariness are associated to metabolic risk (MR) factors in children.

PURPOSE: To study the relationship between different PA intensities [moderate to vigorous PA (MVPA) and light PA (LPA)] and sedentariness with children MR.

METHODS: The sample comprises 388 Portuguese children, from both sexes (219 girls; mean age 10.5 years). MR indicators included fasting glucose, triglycerides, HDL-cholesterol, as well as waist circumference and mean arterial blood pressure; MR score (zMR), adjusted for maturity offset, was computed. MVPA, LPA, and sedentariness were measured with the GT3X+ Actigraph accelerometer with at least 4 days (with one weekend day) of at least 10 hours/day of monitoring. Linear regression, by sex, was used to identify correlates of zMR. **RESULTS:** In girls, none of the variables included in the model were significantly related to zMR ($p>0.05$); however, in boys a negative and significant effect of MVPA was observed ($\beta=-0.026$; $p=0.011$), where those who spent more time in MVPA had a better zMR profile, but no significant effect was observed for LPA or sedentariness. **CONCLUSIONS:** The role of PA on MR in children differs according to gender. In girls no significant link was observed, suggesting that other factors (namely biological and nutritional) may be associated with girls' metabolic health. In boys MVPA is a relevant predictor in their metabolic health, suggesting that MVPA should be promoted. Study funded by The Portuguese Foundation of Science and Technology (individual grant SFRH/BPD/1231452016).

Parent Physical Activity Is More Associated With Child Sport Participation Than Accelerometer-Assessed Child Physical Activity

Brooke E. Wagner, Daheia J. Barr-Anderson, FACSM, Jayne A. Fulkerson. University of Minnesota - Twin Cities, Minneapolis, MN. (Sponsor: Daheia J. Barr-Anderson, FACSM)
 Email: wagn0900@umn.edu
 (No relevant relationships reported)

Parent physical activity (PA) levels may influence the PA levels of their children, either through general activity or sport participation. However, the strength of those associations needs further exploration. Moreover, factors such as child PA self-efficacy, family support of PA, and family structure may also influence these associations and research is lacking among rural families. **PURPOSE:** To examine the associations between parent PA levels and child PA levels including sport participation, and to further explore the role of the aforementioned variables in the relationship. **METHODS:** Baseline data were analyzed on 105 child-parent dyads (child age = 8.95 ± 1.1 years, parent age = 37.9 ± 5.4 years) from the NU-HOME study, a childhood obesity prevention, RCT in a rural community. Data included parent self-reported PA (daily total PA and daily total moderate-to-vigorous PA (MVPA)), family structure (child to adult ratio), and child sport participation in the past year; child-reported PA self-efficacy and family support for PA; and objective child PA levels from accelerometry (daily total PA and daily total MVPA). Child daily total MVPA did not meet acceptable normality and was log transformed for analyses. Multivariate regression models controlling for economic assistance were analyzed using SAS 9.4. **RESULTS:** Children participated in 2.4 ± 1.5 sports in the past year. Mean child daily total MVPA was 44.9 ± 18.6 minutes, while mean parent daily total MVPA was 25.5 ± 25.3 minutes. Parent PA was not significantly associated with child daily total PA or child daily total MVPA. However, after adjusting for economic assistance, parent PA was significantly associated with child sport participation separately ($p<0.005$) and in models that included child PA self-efficacy, family support of PA, and family structure ($p<0.02$). **CONCLUSIONS:** Present study findings that parent PA was significantly associated with child sport participation, but not objective measures of child PA suggests that active parents may encourage and support their children's sport participation. Sport participation may provide personal, social, as well as physical benefits for children. The findings of this study highlight the importance of exploring sport participation when investigating activity behavior particularly among rural children.

DIABETES RISK STATUS AND PHYSICAL ACTIVITY IN WOMEN OF CHILDBEARING AGE: U.S. BRFS

Bethany Grace Rand, Tammie M. Johnson, Michelle L. Stone, Michael R. Richardson, James R. Churilla, FACSM. University of North Florida, Jacksonville, FL. (Sponsor: James Churilla, PhD, FACSM)
 Email: n00829141@unf.edu
 (No relevant relationships reported)

PURPOSE: Women of childbearing age with prediabetes (PD) or gestational diabetes (GD) can reduce their odds of diabetes by engaging in physical activity (PA). This study examined the odds of meeting the current United States aerobic activity (AA), muscle-strengthening activity (MSA), both, or neither recommendation(s), according to diabetes risk status (DRS).

METHODS: Women (N=282,302) ages 18-44 who participated in the 2011, 2013, 2015, or 2017 Behavioral Risk Factor Surveillance System survey were categorized by DRS: no diabetes (ND), diabetes (DM), or high risk for diabetes (HRD). Logistic

regression models stratified by body mass index (underweight [<18.5], desirable weight [$18.5-24.9$], overweight [$25.0-29.9$], and obese [≥ 30.0]) were fitted, controlling for potential confounders.

RESULTS: Compared to the ND referent group, overweight women with DM had significantly ($p \leq 0.05$) lower odds of meeting the AA recommendation (OR 0.83, CI 0.67-1.00). Overweight women considered HRD were less likely to meet the MSA recommendation (OR 0.81, CI 0.68-0.97) and more likely to not meet either recommendation (OR 1.20, CI 1.03-1.40). Among women in the desirable weight group, those considered HRD had lower odds of meeting MSA only (OR 0.72, CI 0.61-0.85) or both recommendations (OR 0.77, CI 0.64-0.93). Desirable weight women with DM had greater odds of not meeting either recommendation (OR 1.43, CI 1.12-1.82). **CONCLUSIONS:** Increased AA and MSA in women at risk for diabetes may benefit maternal outcomes. Strategies targeting the determinants of PA should be considered to increase participation.

2177 Board #98 May 28 2:00 PM - 3:30 PM
Exploring Associations Between Household Chaos With Sedentary Behavior And Screen Time In Rural Children

Stephanie M. Grace, Daheia J. Barr-Anderson, FACSM, Jayne A. Fulkerson. *University of Minnesota, Twin Cities, Minneapolis, MN.* (Sponsor: Daheia J. Barr-Anderson, FACSM)
 Email: grace130@umn.edu
 (No relevant relationships reported)

Household chaos is perceived home disorganization caused by noise, crowding, and traffic patterns. It has been shown to be linked to weight-related behaviors such as sleep and nutritional behaviors (i.e., family meals). However, the relationship between sedentary behavior and household chaos has not been explored. Examining this association could allow us to better understand how family milieu contributes to behavioral risk factors for childhood obesity. **PURPOSE:** To examine associations between household chaos with sedentary behavior and screen time in rural children. **METHODS:** Participants ($n=105$ parent/child dyads) were enrolled in the NU-HOME study, a family-based, obesity prevention RCT in rural Minnesota. Parents reported baseline data on sociodemographics, household chaos, and child screen time. Household chaos was measured with a 15-item scale about home disorganization ($\alpha=0.83$; higher scores indicate more chaos). Children's sedentary behavior was assessed via accelerometry. Regression analyses using SAS 9.4 were performed to assess associations between household chaos and sedentary behavior and screen time, controlling for child-parent ratio, economic assistance, child BMI z-score and age. Normality of screen time was not met, so a transformed variable was used in analyses. **RESULTS:** Child mean age was 8.95 ± 1.05 years; 59% were female; mean BMI z-score = -0.92 ± 0.94 . Mean daily sedentary time and screen time were 8.33 ± 77.5 and 2.06 ± 1.42 hours, respectively. Household chaos scores had a mean of 5.04 ± 3.6 , which is comparable to other studies. Household chaos scores were not significantly associated with child sedentary behavior but were positively associated with child screen time ($p=0.002$). **CONCLUSIONS:** In other studies, household chaos has been associated with negative health behaviors, which aligns with our current findings. The association between screen time and household chaos may be explained by parents using electronics to entertain children in chaotic environments. Parents in chaotic homes may also have more difficulty managing a child's screen time than those in less chaotic homes. The relationship between household chaos and sedentary behavior should be further explored to increase our understanding of how the home environment may affect health-related behaviors.

2178 Board #97 May 28 2:00 PM - 3:30 PM
Meeting 24-hour Movement Guidelines: Prevalence, Correlates And Relationships With Overweight And Obesity Among Chinese Children And Adolescents

Yang Liu¹, Si-Tong Chen¹, Mark S. Tremblay, FACSM², Jin-Tao Hong¹, Yan Tang¹, Zhen-Bo Cao¹, Jie Zhuang¹, Zheng Zhu¹, Pei-Jie Chen¹. ¹Shanghai University of Sport, Shanghai, China. ²Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada. (Sponsor: Mark S. Tremblay, FACSM)
 Email: docliuyang@hotmail.com
 (No relevant relationships reported)

There is a lack of research on meeting 24-hour movement guidelines, including physical activity (PA), sedentary time (ST) and sleep, among Chinese children and adolescents. **PURPOSE:** To investigate the prevalence of meeting the 24-hour movement guidelines, related correlates, or the relationships with body mass index (BMI) among Chinese children and adolescents. **METHODS:** Cross-sectional data were derived from the Physical Activity and Fitness in China—The Youth Study (PAFACTYS) 2017. A nationally representative sample with 114,072 children and adolescents (9-18 years-old, mean age 13.75 years, 49.2% boys) completed a self-report questionnaire regarding PA, ST and sleep. The prevalence of meeting the 24-hour movement guidelines and World Health Organization (WHO) weight status

categories was determined. Generalized linear models were used to determine the correlates of meeting the movement guidelines and the relationships of meeting the movement guidelines with overweight and obesity (OW/OB). **RESULTS:** Only 5.12% of Chinese children and adolescents met the 24-hour movement guidelines and 22.44% were classified as OW/OB. Children and adolescents meeting the 24-hour movement guidelines showed lower odds ratios for OW/OB. Compared with meeting the 24-hour movement guidelines, boys of 4-6th grades (9-12 years old) meeting none of the recommendations (OR = 1.22), ST recommendation only (OR = 1.13) and sleep recommendation only (OR = 1.14) had significantly higher odds ratios for OW/OB. Similar trends were observed in girls of 4-6th grades meeting none of the recommendations (OR = 1.35), sleep recommendation only (OR = 1.23) and PA + sleep recommendations (OR = 1.24), and in girls of 7-9th grades (13-15 years old) meeting none of the recommendations (OR = 1.30). **CONCLUSIONS:** Very few Chinese children and adolescents met the integrated health-related 24-hour movement guidelines. Age (negative), parental educational level and family income (both positive) were correlates of meeting the 24-hour movement guidelines. Children and adolescents meeting the 24-hour movement guidelines were more likely to have healthier body weight, especially in the youngest age group, and girls in middle age group. **Funding:** Supported by the General Project of the National Social Science Foundation of China (19BTY077).

2179 Board #98 May 28 2:00 PM - 3:30 PM
The Association Between Socioeconomic Status And Access To Physical Activity Related Built Environment In Children

Monet C. Gilmore, Gabby Ferrara, Kimberly A. Reich. *High Point University, High Point, NC.*
 (No relevant relationships reported)

Minorities and those with lower socioeconomic status (SES) are at higher risk for chronic diseases compared to their Caucasian counterparts and those with higher SES. Establishing life-long physical activity (PA) behavior in childhood could lower the risk for chronic disease in adulthood. Access to opportunities for PA in the built environments is associated with increased PA behavior in children. Understanding patterns of access to these opportunities for minority and low SES children would be useful in developing interventions to increase PA in these populations. **PURPOSE:** To investigate the relationship among race, SES, proximity to public parks for children and adolescents in a mid-sized city. **METHODS:** ArcGIS Online was used to map public parks with 10-minute walking buffers, census tract-level demographics (race of children and adolescents [≤ 19 yrs], household poverty status, and population density). Central city neighborhoods were also mapped. Partial correlations between the variables were performed, controlling for all other variables. Hierarchical cluster analysis identified homogeneous census tracts with regard to race, SES, park proximity, and population density. One-way ANOVA measured differences in the variables used to construct the clusters. Significance was set at $p < 0.05$. **RESULTS:** Poverty correlated with black race ($r^2=0.60$, $p < 0.001$) and park proximity ($r^2=0.53$, $p=0.54$), but there was no significant correlation between race and park proximity. Population density correlated with black race ($r^2=0.63$, $p < 0.001$), but not with any other variables. Two census tract clusters were identified. Parks in cluster 1 corresponded with neighborhoods centrally located in the city. Compared to cluster 2, cluster 1 showed higher percentages of households below the poverty level (36.1 ± 13.2 vs 4 ± 8.6), children and adolescents of black race (63.4 ± 18.6 vs 30.3 ± 18.3), and children and adolescents living within 10-minute walking distance to a park (76.7 ± 16.7 vs 8.0 ± 11.4). **CONCLUSIONS:** Abundant proximity to parks may provide opportunities for physical activity interventions for at-risk children and adolescents in urban areas. Future directions should include the investigation of additional aspects of access in these subgroups such as patterns of PA-promoting park amenities.

2180 Board #99 May 28 2:00 PM - 3:30 PM
Association Of Household Food Security And Physical Activity Among Youth And Young Adults With Diabetes

Lauren A. Reid¹, Marco Geraci¹, Jason A. Mendoza², Beth A. Reboussin³, Russell R. Pate, FACSM¹, Katherine A. Sauder⁴, Lawrence M. Dolan⁵, Grace Kim⁶, Jean M. Lawrence⁷, Angela D. Liese¹. ¹University of South Carolina, Columbia, SC. ²University of Washington, Seattle, WA. ³Wake Forest School of Medicine, Winston Salem, NC. ⁴University of Colorado School of Medicine, Aurora, CO. ⁵University of Cincinnati, Cincinnati, OH. ⁶Seattle Children's Research Institute, Seattle, WA. ⁷Kaiser Permanente Southern California, Pasadena, CA.
 Email: lareid@email.sc.edu
 (No relevant relationships reported)

Physical activity (PA) is so essential in diabetes management that it is usually prescribed as a lifestyle change in addition to medications. Food insecurity may cause youth and young adults (YYAs) with diabetes to be more fatigued, thereby negatively impacting their PA.

PURPOSE: The purpose of this study is to examine the association between household food security and PA in YYAs with diabetes.
METHODS: Data from 2,195 YYAs with diabetes (1,855 type 1, 340 type 2, mean age: 21.4 years) were analyzed from the SEARCH for Diabetes in Youth Study. Household food security status was measured with the 18-item U.S. Household Food Security Survey Module by adult participants or parents of minors. Households that affirmed ≥ 3 food insecure conditions or behaviors were considered food insecure. PA was measured with the International Physical Activity Questionnaire Short Form. Walking, moderate (excluding walking) intensity physical activity (MPA), and vigorous intensity physical activity (VPA) minutes/week were multiplied by 3.3, 4.0, and 8.0, respectively, to obtain metabolic equivalent minutes (MET min/wk), and summed to calculate total PA MET min/wk. We conducted median regression analyses, adjusting for socioeconomic, demographic and clinical covariates, for both the full sample and by diabetes type.

RESULTS: 20% of the sample (15% type 1, 5% type 2) was food insecure. The median amount of walking, MPA, VPA, and total PA were 991, 481, 955, and 2,967 MET min/wk, respectively. In the unadjusted analysis, food insecurity was significantly associated with less VPA (β : -480; $p=0.0067$) and more walking (β : 399; p -value=0.0006) MET min/wk. The effect for walking persisted after covariate adjustment (β : 242; $p=0.0238$). There was no significant difference observed by diabetes type.

CONCLUSION: Household food security was not associated with MPA, VPA, or total PA MET min/wk in adjusted analyses. Food insecurity was associated with more walking MET min/wk. Future research should consider walking for travel vs. walking for leisure among food insecure YYAs with diabetes. Future research should also consider use of an objective measure of PA in contrast to the present study which relied on subjective recall.

Supported by NIH Grant R01DK117461.

Metabolic Syndrome And Muscular Strength In Youth: NHANES 2011-2014

Nicholas M. Pilli, Tyler J. Kybartas, Kristen M. Lagally, FACSM, Kelly R. Laurson. *Illinois State University, Normal, IL.* (Sponsor: Kristen M. Lagally, FACSM)
(No relevant relationships reported)

Muscular strength has recently been identified as a potential target of cardiometabolic risk-factor reduction strategies in youth. Initial explorations have indicated links between muscular strength and individual components of metabolic syndrome, but large, nationally-representative research on the topic is limited. **PURPOSE:** To investigate the relationship between metabolic syndrome and muscular strength in a nationally representative sample of U.S. youth. **METHODS:** The analysis included 409 boys and 415 girls from the 2011-2014 National Health and Nutrition Examination Survey between 12-18 years of age. Metabolic syndrome was defined by the Jolliffe and Janssen criteria and based on having 3 or more of the following components: abdominal obesity, high triglycerides, low HDL cholesterol, elevated blood pressure, or high fasting glucose. Muscular strength was assessed via handgrip dynamometer and expressed as age- and sex-specific z-scores of relative strength (kg strength/kg body mass). Low strength was defined as a relative grip strength below the 25th age- and sex-specific percentile. Logistic regression was used to estimate the odds of metabolic syndrome based on relative strength z-score. An additional model compared the odds of metabolic syndrome between youth in low and adequate strength groups. All analyses controlled for age, sex, race/ethnicity, physical activity status, and weight status. **RESULTS:** The prevalence of metabolic syndrome was 5.3% (95% CI 3.9% to 7.3%). The logistic regression indicated that for every 1 unit decrease in strength z-score, the odds of metabolic syndrome increased by 2.6 (95% CI 1.7 to 4.1). Further, adolescents with low strength were more likely to have metabolic syndrome than those with adequate strength (odds ratio = 2.2, 95% CI 1.1 to 4.3). **CONCLUSIONS:** Muscular strength is predictive of adolescent metabolic syndrome. Youth with low strength are more than twice as likely to have metabolic syndrome than those above the bottom strength quartile, irrespective of physical activity and weight status. These results highlight the relevance of muscular strength in the prevention of youth cardiometabolic disease and metabolic syndrome.

2182 Board #101 May 28 2:00 PM - 3:30 PM
Physical Activity And Sedentary Behaviors Vary According To Fitnessgram Bmi Classification In Youth

John L. Walker, FACSM¹, Kevin W. McCurdy¹, Anthony J. Clapp². ¹Texas State University, San Marcos, TX. ²Augsburg University, Minneapolis, MN.
(No relevant relationships reported)

FITNESSGRAM has established criterion standards for aerobic fitness, as well as body composition and body mass index (BMI) according to gender and age in youth. **PURPOSE:** The purpose of this study was to determine the variation in reported amounts of physical activity (PA) and sedentary behaviors (SB) according

to FITNESSGRAM BMI classification in youth. **METHODS:** Subjects were 1,643 boys and girls, ages 11-17 years, who participated in the 2014 FLASHE Study, a national epidemiological survey regarding psychosocial, general, and environmental factors of various health behaviors. Participants' responses regarding levels of PA and SB were compared across FITNESSGRAM BMI classifications, more specifically between participants categorized as either Very Lean (VL) or within the Health Fitness Zone (HFZ) versus those participants in the Needs Improvement (NI) categories. **RESULTS:** Participants classified as NI for BMI reported significantly less PA outside of school ($p = .004$), as well as significantly greater sedentary time outside of school ($p = .003$) than participants classified as either VL or within the HFZ. Participants classified as NI for BMI also reported significantly greater predicted time (minutes) per week in SB outside of school ($p < .001$), significantly greater predicted time (minutes) per day in SB outside of school ($p < .001$), and significantly greater predicted proportion of time (percentage) in SB outside of school ($p < .001$) than participants classified as either VL or within the HFZ. No significant difference in responses between participants classified as NI compared to those classified as either VL or within the HFZ were observed for predicted time per day or week in moderate-to-vigorous PA at school or during the weekend. **CONCLUSIONS:** FITNESSGRAM BMI classifications have been shown to be consistent with ratings of aerobic fitness. These data suggest that youth classified as NI according to FITNESSGRAM BMI standards have similar in-school and weekend PA and SB patterns as youth classified as either VL or within the HFZ; however, youth classified as NI engage in less PA and more SB outside of school. To reverse the trend toward greater overweight and obesity among youth, it may be important to address PA and SB patterns.

What Determine Physical (In)Activity In Brazilian Adolescents?

Mabliny Thuany, Thayse Natacha Gomes. *Federal University of Sergipe, São Cristóvão, Brazil.*
 Email: mablinsantos@gmail.com
(No relevant relationships reported)

Increases in physical inactivity has being pointed as one of the most relevant public health problems, especially among youth. Once physical (in)activity is a multifactorial trait, determined by different variables, such as biological and environmental, understanding the role of these variables in youth physical activity (PA) guidelines compliance seems to be of relevance, especially in Brazilian context, given the diversity observed among its region. **PURPOSE:** To describe differences in adolescent's PA guidelines compliance among Brazilian regions and to investigate the determinants related to these differences.

METHODS: Data comes from the National Adolescent School-based Health Survey (PENSE). Sample comprises 99570 Brazilian students (51.7% girls), enrolled in the 9th grade of Elementary School (mean age 14.29±0.93y). Information related to daily PA guidelines compliance was self-reported (based on the number of days, in last week, adolescents were engaged in at least 60 minutes of moderate to vigorous PA), as well as mother educational level; further, school context information (school size and availability of sports court) was obtained. Logistic regression analysis was computed in SPSS 24, with a significance level of 95%.

RESULTS: More than 2/3 of the adolescents did not comply the PA guidelines on any given day of the week; more, the North region presented the highest compliance percentage (9.8%), followed by the Midwest (9.6%), South (8.6%), Southeast (8.3%), and Northeast (7.8%) regions. Regarding predictors of PA guidelines achievement, boys (OR: 3.33, $p<0.001$), older adolescents (OR: 1.08, $p<0.001$), those with mother with higher educational level (OR: 1.33, $p<0.001$), and those enrolled in schools without sports court (OR: 0.92, $p=0.007$) were more prone to be active than girls, young adolescents, those with mothers with lowest educational level, and those enrolled in schools with sports court, respectively. No significant result was found for school size ($p = 0.558$). **CONCLUSIONS:** Sex, age, mother educational level, and the presence of sports court at school were significant predictors for compliance of PA guidelines among Brazilian adolescents. These results reinforce that biological and environmental characteristics, namely school context, play important roles in youth health habits.

Physical Activities Status Of Yi Nationality Pupils In China

Xiaodong SONG. *Chengdu Sport University, Chengdu, China.* (Sponsor: Tongjian YOU, FACSM)
 Email: 756234372@qq.com
(No relevant relationships reported)

Regular physical activity in children and adolescents promotes health and fitness and youth who are physically active are healthier, have less body fat, and exhibit improved cognition and mental performance. Youth need at least 60 minutes of moderate-to-vigorous physical activity each day for good health. **PURPOSE:** Many researches have been done about physical activity levels among youth in China, but most of them

focused on urban children, less known about rural ones, especially minority in poverty areas in China. The main purpose of this article is to investigate the levels of physical activity among Yi nationality pupils in Sichuan province of China. **METHODS:** 7-Day Physical Activity Recall Questionnaires were used to investigate the amount of physical activities among 123 Yi Nationality Pupils (53 boys, 51 girls) aged 9 to 17 (born in 2002-2009) in grade 4 and grade 6.

RESULTS: For the participants, their average total amount of physical activities is 1088 minutes per week, and boys are more physically active than girls (boys in grade 6 is 1376 and girls is 791, boys in grade 4 is 1209 and girls is 979); their average total amount of physical activities at school is 375 minutes per week, and boys are relatively more physically active than girls at school (boys in grade 6 is 394 minutes per week and girls is 285, boys in grade 4 is 366 minutes per week and girls is 363); their average total amount of house work activities at home is 15 minutes per week, and boys are relatively more than girls (boys in grade 6 is 17 minutes per week and girls is 10, boys in grade 4 is 18 minutes per week and girls is 13); only there are 16.2% of pupils whose daily PA amount are below to the recommended daily physical activities of WHO and ACSM (boys in grade 6 is 6 and girls is 3, boys in grade 4 is 4 and girls is 5). **CONCLUSIONS:** Boys are more physically active than girls; Most of pupils reached the recommendation of daily physical activity.

2185 Board #104 May 28 2:00 PM - 3:30 PM

Behavioral Factors For Adolescents' Obesity And Overweight: Physical Activity, Sleep, Sedentary Behavior, And Diet

Jong Cheol Shin, Diana S. Grigsby-Toussaint. *Brown University, Providence, RI.*

Email: jong_cheol_shin@brown.edu

(No relevant relationships reported)

PURPOSE: To investigate the risk factors in weight status among adolescents regarding dietary habits and movement behavior.

METHODS: Primary data were derived from the CDC Youth Risk Behavior Survey (YRBS), a nationally representative sample of 40,130 grade 9-12 students (N=20,340 boys and 19,790 girls) from 2011 to 2017. The prevalence of overweight and obesity was examined using by BMI percentile and then compared based on various demographics (i.e., sex, age, race) and behavioral factors (i.e., physical activity, sedentary time, sleep, soda consumption). Logistic regression analysis was conducted to illustrate the differences in weight status within each group of physical activity levels after control the behavioral and demographic factors.

RESULTS: Overall, African-American adolescents had the highest prevalence of overweight or obesity (36%), followed by Hispanics (35%), others (29%), and White (27%). Female students had significantly lower obesity rate than male students (-6.4 ± 0.2%), but also spend less time for behavioral activities (e.g., sedentary time: -0.372 ± 0.015 hours, MVPA -20.4 ± 0.4%, and strength training -20.9 ± 0.3%). The self-diagnosis was relatively accurate, with 69% of true positive and 13% of true negative in comparison to actual overweight and obesity status. For the PA group, students who satisfied both PA recommendations had less likely to be obese compared to non-PA group: Odds Ratio (OR) for PA = 0.89, 95% CI [0.825, 0.961], p = 0.003; OR for strength training = 0.92, 95% CI [0.865, 0.996], p = 0.039. Students who consumed soda on more than one day were more likely to be obese (OR = 1.13, 95% CI [1.049, 1.223]), and students who had more sedentary time tended to be obese (OR=1.03, 95% CI [1.011, 1.041]).

CONCLUSIONS: Students who were meeting PA recommendations were less likely to be obese, while students who had more sedentary time and higher levels of soda consumption were more likely to be obese. In addition, African American and Hispanic students were more likely to be overweight and obese.

Peak Height Velocity Maturity Offset Estimated From Cross-sectional Vs. Longitudinal Growth Data

Jodi N. Dowthwaite¹, Matthew J. Pelowski², Jennifer E. Minassian², Tamara A. Scerpe³. ¹SUNY Upstate Medical University, Syracuse, NY. ²Binghamton University, Binghamton, NY. ³University of Wisconsin - Madison, Madison, WI. (Sponsor: Jill Kanaley, FACSM)

Email: dowthwaj@upstate.edu

(No relevant relationships reported)

Appropriate evaluation of pediatric health indices relies on assessment based on physical maturity status. Regression equations have been developed to estimate maturity offset (MO) relative to age at peak height velocity (aPHV) using cross-sectional anthropometric data, with extensive application in pediatric exercise research.

PURPOSE: We evaluated agreement of these estimates against standards calculated using superimposition by translation and rotation (SITAR) models of longitudinal data, targeting specific time windows relative to PHV and menarche. **METHODS:** Height data were drawn from a longitudinal dataset evaluating female bone growth in 141 participants for whom SITAR-based aPHV had been calculated using ≥ 3

data points. Two subsamples were selected based on available repeated measures in target maturity ranges based on SITAR aPHV and menarche: prePHV (-2.5 to -1.5yr), postPHV (+1.5 to +2.5yr); circaPHV (-0.5 to +0.5yr) & postMEN (0 to +1.0yr). Mirwald et al. and Moore et al. regression equations were used to calculate aPHV and MO, yielding MO1 and MO2 (respectively) for comparison against sitarMO. Bland-Altman plots evaluated agreement with sitarMO in each target maturity range. **RESULTS:** For prePHV and postPHV comparisons, n= 58, with mean sitarMO -2.1yr (sd 0.3) and +2.1yr (sd 0.3), respectively. For circaPHV & postMEN comparisons, n=108, with mean gynecological ages -1.1yr (sd 0.7) and +0.6yr (sd 0.3) and mean sitarMO -0.1yr (sd 0.4) and +1.6yr (sd 0.7), respectively. Except postMEN, on average, MO₁ underestimated sitarMO [prePHV -1.5yr, postPHV -2.8yr; circaPHV = -2.3yr, postMEN = +0.5yr]. Mean discrepancies for MO₂ vs. sitarMO were subtle, near zero [prePHV = +0.4yr, postPHV = +0.1yr; circaPHV = -0.1yr, postMEN = -0.01yr]. **CONCLUSION:** MO₁ maturity estimates are flawed; <50% of estimates were within 1yr of sitarMO for assessed maturity ranges. MO₂ provides better sitarMO estimates using cross-sectional data. However, it is unclear whether MO₂ is an improvement over chronological age for most individuals, as MO₂ effectively assesses whether girls are short or tall for their age. In many cases, height for age may primarily reflect genetic height potential rather than maturity status, particularly at older maturity stages.

Extent Of Childhood Participation In Ultramarathon Running Does Not Negatively Impact Continued Running

Lydia J. Henderson¹, Volker Scheer², Martin D. Hoffman, FACSM³. ¹University of California Davis, Sacramento, CA. ²Universidad a Distancia de Madrid (UDIMA), Madrid, Spain. ³VA Northern California Health Care System, Sacramento, CA. (Sponsor: Martin D. Hoffman, FACSM)

(No relevant relationships reported)

PURPOSE: It is unclear if "excessive" exercise is harmful, particularly at a young age. While childhood participation in ultramarathons has increased exponentially over the past 20 years, less than 25% of these individuals continue running ultramarathons in adulthood. This raises concern that childhood ultramarathon runners may suffer complications from their young participation in the sport. The purpose of this work was to examine if the extent of ultramarathon participation among those under 19 years of age is related to the cessation of running into adulthood due to running related injuries.

METHODS: Individuals having completed an ultramarathon when under 19 years of age were recruited via announcements on running-related websites and Facebook advertisements. Qualified participants were also identified from race results databases, and directly recruited when online publicly available contact information was found. Participants completed an online survey including questions on running history, whether or not they are currently running and reasons for not if that was the case, and their opinions about how childhood ultramarathon running had impacted their health. Group comparisons were made with an unpaired t-test or the Mann-Whitney test.

RESULTS: There were 69 participants (9 women and 60 men) completing the survey with median age of 34 years (range 18-67 years). Those who had stopped running regularly due to running-related injury (12%) had not completed more ultramarathons when under 19 years of age compared with those who had either stopped for other reasons (28%) or continued to run regularly (median 1 vs. 2, p=.13). The age of these two groups was also similar (p=.51). All but one respondent (1%) indicated that they believed running an ultramarathon as a child had either a positive (67%) or no (32%) effect on their physical health. **CONCLUSIONS:** Cessation of running into adulthood due to running related injuries was unrelated to the number of ultramarathons completed while under 19 years of age. Childhood ultramarathon runners also largely felt that ultramarathon running as a child had a favorable effect on their health. These findings suggest that the extent of childhood ultramarathon running does not adversely affect running into adulthood. Supported by the Ultra Sports Science Foundation

SLEEP DURATION AND OBESITY INDICES IN U.S. ADOLESCENTS (NHANES 2015-2016)

Megan E. Holmes, Sarah E. Thompson, Robert Booker.
Mississippi State University, Mississippi State, MS. (Sponsor:
 Rebecca Batista, FACSM)
 Email: mholmes@colled.msstate.edu
 (No relevant relationships reported)

Adolescent obesity continues to be a major public health concern among developed nations. Sleep duration has been hypothesized as a contributing factor to this increase. **PURPOSE:** This study examined the sleep-obesity relationship in U.S. adolescents. **METHODS:** Data from the 2015-2016 National Health and Nutrition Examination Survey ($n=454$; ages 16-18 years) was used to consider the effect of sleep duration (hours) on body mass index (BMI) and waist circumference (WC) by gender. Linear regression was used to determine the relationship between sleep duration and BMI and WC. Sleep hours were then categorized as Under Recommended (<7 hours), Recommended (8-10 hours), and Over Recommended (>10 hours) and an ANCOVA was used to examine differences in BMI and WC by sleep category. Finally, logistic regression considered the influence of sleep category on overweight classification. **RESULTS:** Approximately 21% of the total participants were overweight or obese while 53.3% met the recommendations for sleep duration. Linear regression revealed a significant ($p<0.05$) main effect across sleep duration categories in the total sample for WC only. Longer sleep duration was associated with an increased WC in both males ($p=0.030$) and females ($\beta=0.143-0.148$, $p<0.05$) and with an increased BMI in males ($\beta=0.136-0.113$, $p<0.05$), but not females. Logistic regression analyses yielded no significant influence of sleep category assignment on overweight BMI classification. **CONCLUSIONS:** For both males and females, excessive sleep was related to higher WC. However, excessive sleep only impacted BMI in males. In contrast, the greater number of females achieving the recommended amount of sleep, and thus, smaller proportion getting insufficient or more than the recommended amount, may contribute to the absence of influence on BMI in females. Likewise, the categories used to classify sleep duration may not be sensitive enough to adequately identify risk differences weight-related maladies in females.

Association Between 90° Push-up And Cardiorespiratory Fitness: Cross-sectional Evidence Of Physical Fitness Surveillance In Youth

Ioannis Liras¹, Toyin Ajisafe². ¹Christus Health-Spohn / Texas A&M Family Medicine Residency, Corpus Christi, TX. ²Texas A&M University – Corpus Christi, Corpus Christi, Texas, Corpus Christi, TX.
 Email: j_liras@hotmail.com
 (No relevant relationships reported)

PURPOSE Musculoskeletal and cardiorespiratory fitness is strongly associated with better health among children, affecting mental and physical outcomes like depression, anxiety, cardiovascular disease risk and body mass indices. It has been shown that fit children with low abdominal adiposity had increased odds of superior academic achievement. To-date there is no adequate surveillance in the US when it comes to monitoring physical fitness. This study investigated associations between musculoskeletal fitness measures (including 90° push-up), cardiorespiratory fitness, and weight. **METHODS** Two hundred and ten students (9.7 ± 1.08 years; 138.6 ± 9.4 cm; 42.3 ± 14.4 kg) across third through fifth grades were tested for cardiorespiratory (i.e., Progressive Aerobic Cardiovascular Endurance Run (PACER)) and musculoskeletal (90° push-up, trunk lift, sit-and-reach and curl-up) fitness. The relationships between the two measures were modeled using a series of linear regression analyses. Models were adjusted for age, sex, and weight status. Significant two-tailed tests were set at $P < .05$. **RESULTS** Of the four musculoskeletal fitness measures, only 90° push-up was significantly associated ($\beta = .35$; $P < .001$) with PACER test scores (i.e., cardiorespiratory fitness). The related model ($R^2 = .32$; $F(4,205) = 26.1$; $P < .001$) accounted for 32% of the variance in cardiorespiratory fitness. 90° push-up was associated with sit-and-reach ($\beta = .29$; $P < .001$) and curl up ($\beta = .41$; $P < .001$) test scores. When individually modeled, 90° push-up ($\beta = -.46$; $P < .001$) and PACER ($\beta = -.44$; $P < .001$) were inversely associated with weight. **CONCLUSION** The 90° push-up test was associated with cardiorespiratory fitness, anterior trunk muscle strength, endurance, lower back and posterior thigh muscle flexibility. Our study concluded that the 90° push-up test is a tractable tool for physical fitness surveillance by clinicians, physical education teachers, parents, and children. We need more studies with larger samples from diverse settings and wider age range to support our findings. Incorporating a surveillance mechanism of fitness in schools, primary care settings and educating parents of its correct use can make an impact on the youth population and decrease the incidence of the growing pandemic of childhood obesity and its associated health risks.

Youth Sports Participation In The United States, 2016-2017

Eric T. Hyde¹, John D. Omura¹, Janet E. Fulton, FACSM¹, Sarah M. Lee¹, Katrina L. Piercy², Susan A. Carlson¹. ¹Centers for Disease Control and Prevention, Atlanta, GA. ²Office of Disease Prevention and Health Promotion, Rockville, MD. (Sponsor: Janet Fulton, FACSM)
 Email: mme7@cdc.gov
 (No relevant relationships reported)

PURPOSE: The *National Youth Sports Strategy* was released in 2019 with an aim to expand participation in sports among US youth. Our study examines differences in the prevalence of youth sports participation by selected characteristics to better understand disparities in participation and how they may vary across age groups. **METHODS:** Nationally representative data from the 2016-2017 National Survey of Children's Health ($N=49,952$) were analyzed. Parents with children aged 6-17 years were asked whether their child participated in a sports team after school or on weekends during the previous 12 months. Prevalence of participation was estimated overall, by age, and sex, race/ethnicity, highest level of parental education, and household income (percentage of the Federal Poverty Level [FPL]). Significant differences and trends, assessed using pairwise t tests and orthogonal polynomial contrasts, are reported ($p<0.05$). **RESULTS:** Overall, 58.4% of youth aged 6-17 years participated in sports. Youth aged 10-13 years had the highest prevalence of sports participation (61.9%) compared to those aged 6-9 years (56.6%) and 14-17 years (56.5%). Prevalence of participation was higher among boys (61.3%) than girls (55.2%) and among non-Hispanic whites (65.4%) compared to non-Hispanic blacks (48.1%), Asians (55.6%), and Hispanics (49.8%). Prevalence increased with increasing parental education level (from 31.9% [highest education level of high school or less] to 73.1% [college degree or higher]) and household income (from 41.1% [household incomes <100% FPL] to 75.7% [$\geq 400\%$ FPL]). Patterns were similar across age groups, although differences by race/ethnicity, parental education, and household income were generally more pronounced in the youngest age group. For example, among youth aged 6-9 years the range in prevalence of participation from lowest to highest income level was 35.4% to 80.6%, while among youth aged 14-17 years it was 43.2% to 68.5%. **CONCLUSION:** While about 6 in 10 youth in the United States participate in sports, important disparities exist particularly by household income and are generally more pronounced among younger children. Identifying and overcoming barriers, such as cost and accessibility, may help increase youth sports participation to support the aims of the *National Youth Sports Strategy*.

2191 Board #110 May 28 2:00 PM - 3:30 PM

National Monitoring Of Youth Physical Activity With Two Surveillance Systems: Healthy People 2030

Tiffany J. Chen, Kathleen B. Watson, Shannon L. Michael, Janet E. Fulton, FACSM, Susan A. Carlson. *Centers for Disease Control and Prevention, Atlanta, GA.*
 Email: pgi8@cdc.gov
 (No relevant relationships reported)

Healthy People 2030 will include a new objective to increase the proportion of younger youth (6-13 years) who meet the aerobic physical activity guideline (guideline). The current objective monitors meeting the guideline in older youth (grades 9-12). Monitoring these two physical activity objectives necessitates the use of two surveillance systems: National Survey of Children's Health (NSCH) and the national Youth Risk Behavior Survey (YRBS). It is unclear how youth physical activity prevalence estimates compare in these surveillance systems. **PURPOSE:** To describe and compare prevalence estimates of youth meeting the guideline, particularly where ages overlap (14-17 years), in the NSCH and the YRBS. **METHODS:** Youth were classified as meeting the guideline if they exercised, played a sport, or participated in physical activity (adult proxy report, NSCH) or were physically active (self-report, YRBS) for at least 60 minutes/day during the past week (NSCH) or 7 days (YRBS). Data from 2016-2017 NSCH ($n=50191$, ages 6-17) and 2015-2017 YRBS ($n=29483$, grades 9-12) were analyzed to estimate prevalence of youth meeting the guideline overall and by age, sex, and race/ethnicity. **RESULTS:** Overall, 25.9% of children aged 6-13 (NSCH) and 26.6% of adolescents grades 9-12 (YRBS) met the guideline (Table). Prevalence differed by sex for all age groups. There were differences by race/ethnicity in youth 6-13 years (NSCH) but not in youth 14-17 years (NSCH and YRBS). When comparing youth 14-17 years, there was a 9.6 percentage point difference in prevalence; patterns by sex and race/ethnicity were similar.

Table. Prevalence with Standard Error (SE) of Youth Meeting Aerobic Physical Activity Guideline by Age Group, NSCH 2016-2017 and YRBS 2015-2017

Characteristics	NSCH, % Meeting Guideline (SE)		YRBS, % Meeting Guideline (SE)	
	6-13 years	14-17 years	Grades 9-12 ^a	14-17 years
Total	25.9 (0.6) ^b	17.4 (0.7)	26.6 (0.7)	27.0 (0.7)
Sex ^c				
Male	28.5 (0.8)	22.6 (1.1)	35.7 (0.8)	36.5 (0.9)
Female	23.2 (0.9)	11.9 (0.7)	17.6 (0.6)	17.9 (0.7)
Race/Ethnicity ^d				
White, non-Hispanic	^v 27.7 (0.6)	16.5 (0.6)	28.1 (1.0)	28.5 (1.0)
Black, non-Hispanic	27.5 (1.8)	20.7 (2.3)	24.3 (1.2)	25.0 (1.5)
Hispanic/Latino	^w 22.9 (1.7)	17.2 (2.0)	25.2 (0.9)	25.5 (0.9)
Other, non-Hispanic	^w 22.5 (1.4)	16.9 (1.9)	25.3 (1.1)	25.7 (1.2)

Abbreviations: NSCH, National Survey of Children’s Health; YRBS, Youth Risk Behavior Survey

^a Mostly aged 14-18 years, but also includes high school students 13 years or younger and over 18 years.

^b Significant difference (p < 0.001) between age groups 6-13 years and 14-17 years.

^c Significant difference (p < 0.001) between males and females overall and for each age group.

^d Within subgroup, values with different superscript letters (v, w) are significantly different from each other (Bonferroni corrected p < 0.05).

CONCLUSION: Our findings suggest similar sex and race/ethnicity patterns but different prevalence estimates of youth meeting the guideline in the NSCH and the YRBS, limiting direct comparability of estimates for the *Healthy People 2030* youth objectives. This could be due to methodological differences between the two systems, such as respondent and aerobic physical activity question.

2192 Board #111 May 28 2:00 PM - 3:30 PM
Higher Education And Income Level May Lead To A Better Chance Of Meeting The Physical Activity Guidelines

Hai Yan. *University of Illinois at Urbana Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)
 Email: haiyan2@illinois.edu
 (No relevant relationships reported)

PURPOSE: Studies have shown that individuals that participate in physical activity on a daily basis are less likely to develop chronic illnesses than those who do not. The Physical Activity Guidelines for Americans is an essential resource for health professionals to provide recommendations on how everyone can improve their health through regular physical activity. However, little was known about its effectiveness and the factors behind meeting the physical activity guidelines. Thus, the aim of this study was to explore and determine the population that is more likely to meet the physical activity guidelines and offer practitioners and policymakers more insight.

METHODS: The data were derived from the California Behavioral Risk Factor Surveillance Survey (BRFSS). The percentage of adults meeting Aerobic Physical Activity guidelines in California were calculated and weighted to the 2010 California Department of Finance population statistics. Comparison analysis was conducted, and the factors associated with meeting the Physical Activity Guidelines were determined.

RESULTS: The results showed that there’s no significant difference in meeting the physical activity guidelines with respect to age, sex and other factors except education and income level. The percentage of the population meeting the physical activity guidelines increased with higher income and education level.

Factor		2013 Percentage (95%CI)	2015 Percentage (95%CI)	2017 Percentage (95%CI)
Education	Less than high school	50.99 (47.15, 54.84)	52.58 (46.95, 58.21)	49.57 (42.70, 56.44)
	High school graduate	64.58 (61.31, 67.85)	64.56 (60.32, 68.80)	63.74 (57.83, 69.65)
	Some college	70.94 (68.25, 73.64)	72.00 (68.49, 75.50)	71.19 (65.24, 77.13)
	College graduate	78.60 (76.47, 80.73)	81.48 (78.72, 84.24)	78.98 (75.33, 82.64)
Income	Less than \$20,000	58.28 (55.32, 61.25)	61.32 (56.93, 65.71)	60.04 (53.23, 66.84)
	\$20,000 to \$34,999	61.95 (58.18, 65.72)	62.79 (57.30, 68.28)	58.83 (51.54, 66.13)
	\$35,000 to \$49,999	66.57 (61.96, 71.19)	70.88 (65.20, 76.56)	59.37 (47.77, 70.97)
	\$50,000 to \$74,999	71.78 (67.81, 75.75)	69.87 (63.71, 76.03)	73.33 (66.58, 80.09)
	\$75,000 to \$99,999	78.16 (74.20, 82.13)	77.44 (72.30, 82.58)	77.92 (70.41, 85.44)
	\$100,000 and above	84.05 (81.36, 86.75)	85.34 (82.32, 88.36)	85.76 (82.33, 89.20)

CONCLUSION: More efforts should be put into improving the physical activity level of the population that has less income and lower education levels.

2193 Board #112 May 28 2:00 PM - 3:30 PM
Device-Assessed Sedentary Time Sex Comparison By Time Of The Day Analysis

María Enid Santiago-Rodríguez, Jared Donald Ramer, Eduardo Esteban Bustamante, FACSM. *University of Illinois at Chicago, Chicago, IL.*
 Email: msanti24@uic.edu
 (No relevant relationships reported)

Sedentary time (ST) has been linked with obesity in children and studies have shown that girls are more sedentary than boys. However, data about ST by specific periods of the day are necessary to determine when girls are more sedentary compared to boys. **PURPOSE:** To determine how US youth ST at different periods of the weekday (before school, during school, afterschool, and evening) and weekend day (morning, afternoon, and evening) differ by sex. **METHODS:** Youth between 6 and 18 years old from NHANES 2003 - 2006 (N = 2,972) were included. Accelerometry restricted dataset was used to determine ST; and to obtain hourly ST (min/hour) we used the Web App for processing NHANES accelerometer data. For the weekday we calculated a mean for the following periods: before school (6:00-7:59 am), during school (8:00 am-2:59 pm), afterschool (3:00-5:59pm), and evening (6:00pm-9:00pm). For the weekend day we calculated a mean for the morning (7:00 - 11:59 am), afternoon (12:00 - 5:59pm), and evening (6:00 - 10:00pm). T-tests were conducted to compare ST during each period for the weekday and weekend day. SAS 9.4 was used to conduct statistical analyses. **RESULTS:** US youth had 885.6 ± 137.1 min/week of ST. T-tests revealed no significant differences in ST before school (Boys: M=47.3±12.8 min/hour; Girls: M=47.0±12.9 min/hour; P = 0.8), afterschool (Boys: M=26.0±8.7 min/hour; Girls: M=28.3±8.6 min/hour; P = 0.7), and evening (Boys: M=28.0±9.0 min/hour; Girls: M=29.6±8.7 min/hour; P = 0.2) during the weekday; neither in the morning (Boys: M=33.6±13.9 min/hour; Girls: M=34.2±13.3 min/hour; P = 0.1), afternoon (Boys: M=26.6±10.0 min/hour; Girls: M=28.6±10.1 min/hour; P = 0.9), and evening (Boys: M=28.7±10.9 min/hour; Girls: M=30.0±10.6 min/hour; P = 0.2) during the weekend. A significant difference in ST was observed during school in which girls (34.4±8.1 min/hour) had more ST compared to boys (31.6±8.8 min/hour); t (2969) = -9.3, p = 0.003). **CONCLUSION:** Findings support the idea that differences in ST by sex in US youth occur during school time and suggest that school interventions may be a potential way to reduce this gap in girls.

THURSDAY, MAY 28, 2020

Social Jetlag And Cardiometabolic Disease Risk In Pre- Adolescents
 Jake C. Diana¹, Nicholas Castro², Jade Blackwell¹, Paula Skidmore³, Sally Lark⁴, James Faulkner⁵, Michelle Williams⁶, Lee Stoner, FACSM¹. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²University of Southern Mississippi, Hattiesburg, MS. ³University of Otago, Dunedin, New Zealand. ⁴Massey University, Wellington, New Zealand. ⁵University of Winchester, Winchester, United Kingdom. ⁶Harvard University, Cambridge, MA. (Sponsor: Lee Stoner, FACSM)
 (No relevant relationships reported)

PURPOSE: Social jetlag (SJL), the inconsistency between an individual's circadian clock and social clock, has been associated with cardiometabolic diseases (CMD) in adults. In pre-adolescents, SJL has been associated with overweight-obesity, but no previous studies have examined associations with CMD risk. The objective of the current study was to determine the associations between sleep duration, sleep disturbances and SJL with CMD risk among preadolescent children. **METHODS:** This cross-sectional study recruited 392 children (50% F) aged 8-10 years from three representative sample sites across New Zealand. Three sleep quality variables were measured: Sleep duration, as reported by caregivers for seven days; sleep disturbances, estimated by the Children's Sleep Habits Questionnaire; and SJL, measured as the absolute difference between midpoints of sleep on weekdays versus weekend days. Eleven CMD risk factors were measured: central and peripheral systolic blood pressure (BP), heart rate, augmentation index, diastolic BP, low density lipoprotein levels, high density lipoprotein levels, total cholesterol, triglycerides, fasting blood glucose, and glycated hemoglobin. Factor analysis identified underlying CMD risk factors. Linear regression models determined the associations between the sleep variables and the CMD risk factors. Models were adjusted for age, sex, and socio-economic status. Effects sizes (ES) were calculated by dividing the beta coefficient (β) by the standard deviation of β , where <0.20 was considered small, > 0.20 to < 0.50 moderate, and > 0.80 large. **RESULTS:** Complete data was available for 332 children (49% F, mean [SD] age = 9.6 [1.13] years old, WHO-BMI = 0.421 [1.17]). Factor analysis revealed four underlying CMD risk factors: blood pressure, cholesterol, vascular health, and carbohydrate-metabolism. Following adjustment for covariates, there was a small association between SJL and the cholesterol factor ($P=0.025$, $ES=0.11$), and a small association between SJL and the carbohydrate-metabolism factor ($P=0.027$, $ES=0.10$). In fully-adjusted multivariate models, sleep duration nor sleep disturbances associated with any CMD factor. **CONCLUSIONS:** Social jetlag is a modifiable and potentially important contributor to cardiometabolic risk in children.

Relationship Between Body Composition And Motor Skills In 3-5 Year Olds: National Youth Fitness Survey
 Aaron P. Wood¹, Amy Gross McMillan², Satomi Ima², Damon Swift², Katrina D. DuBose, FACSM². ¹University of Tennessee, Knoxville, TN. ²East Carolina University, Greenville, NC.
 Email: awood46@vols.utk.edu
 (No relevant relationships reported)

Factors such as obesity and motor skill development are associated with the health and development of young children and tend to track into adulthood. Early childhood is considered a critical time period for obesity incidence and motor skill development. **PURPOSE:** This study examined the associations between weight status and motor skills in children. **METHODS:** Data from 3-5 years old children (N=342, 51% males) who participated in the 2012 National Youth Fitness Survey were analyzed. Body mass index (BMI), along with age- and sex-adjusted BMI percentiles were calculated. Scores were placed into categories of underweight/healthy weight, overweight, or obese. Skinfold measurements (calf and triceps) were taken and percent body fat (%BF) was calculated using sex-specific equations. Motor skills were determined by the Test of Gross Motor Development-2nd Edition. Linear regression analyses were performed to determine the associations among BMI category and Locomotor, Object Control, and overall Gross Motor Quotient (GMQ) controlling for sex, race, and poverty index ratio. Regression analyses were also conducted between %BF and Locomotor, and Object Control Motor Skills and GMQ controlling for sex, race, and poverty index ratio. **RESULTS:** Most children were classified as underweight/healthy weight (69%) and 31% were overweight or obese. Average BF% was $M(SE)=17.02 (0.27)$. In regard to GMQ, the mean percentile was 41.43 (1.36). Neither BMI category or BF% was related to Locomotor, Object Control, or GMQ ($p=0.32-0.71$, and $p=0.18-0.63$, respectively). **CONCLUSIONS:** Given the inconsistent findings in the literature, additional research is needed to elucidate these relationships between body composition and motor skill development. Using different measures of weight status may provide additional insight into associations between weight status and motor skill development in young children.

High Relative Handgrip Strength Is Inversely Associated With The Incidence Of T2DM In Adults
 Soo Hyun Park¹, Eun Sun Yoon¹, Saejong Park¹, Taekyung Han². ¹Korea Institute of Sport Science, Seoul, Korea, Republic of. ²Andong National University, Andong, Korea, Republic of.
 Email: otajulia@kspo.or.kr
 (No relevant relationships reported)

Several studies indicated that handgrip strength, which is a measuring tool for muscle strength, is associated with type 2 diabetes mellitus (T2DM). However, the results have been conflicting and few studies that used data from adults in Korea have been conducted. In addition, an increase in body weight usually precedes the development of DM and research an adjustment of handgrip strength to body weight is needed. **Purpose:** We investigated whether relative handgrip strength (RHS) is associated with development of type 2 DM in a subset of data with Korean Genome and Epidemiology Study. **Method:** We included 76,465 participants (25,870 male) aged between 40 and 79 years who had undergone a handgrip test from 39 community health examination centers located in 14 urban areas in Korea between 2004 and 2013. DM was defined as an fasting blood glucose ≥ 126 mg/dl or use of an oral hypoglycemic agent as diagnosed by a physician. The RHS was calculated by dividing maximal handgrip strength by body mass index and further grouped into age- and sex-specific tertiles. **Result:** During an average follow-up 5 years, 1,214 (1.7%) of the 69,725 participants with normoglycemia at baseline had newly developed DM. The hazard ratio and 95% confidence interval (CI) of incident DM in the lowest tertiles of RHS versus the middle and highest were 0.82 (95% CI 0.67 to 0.99) and 0.69 (95% CI 0.55 to 0.86) in male and 0.84 (95% CI 0.70 to 1.00) and 0.56 (95% CI 0.45 to 0.69) in female, respectively, after adjusting for potential confounders, including age, family income and education level, marry status, smoking, alcohol consumption, hypertension, baseline fasting blood glucose, family history of diabetes and physical activity. The participants with sustained high RHS had significant 50% lower risk of DM incidence (male, HR 0.50, 95% CI : 0.35-0.71, female HR 0.49, 95% CI : 0.36-0.67) compared with the those with the remained low RHS during 5 years of follow-up. **Conclusion:** The current finding suggests that RHS predicts incidence of type 2 DM independent of potential confounders in Korea middle-aged and older adults and maintaining of high RHS may be important for prevention of the development of the DM.

Comparing And Explaining Membership Length And Attendance Behaviour Of Women In Female-only And Mixed-gender Gyms
 Nadja Willinger¹, James Steele², Gary Liguori, FACSM³, Lou Atkinson⁴, Steve Mann⁵, Alfonso Jimenez⁶, Elizabeth Horton¹. ¹Coventry University, Coventry, United Kingdom. ²Solent University; ukactive Research Institute, Southampton; London, United Kingdom. ³University of Rhode Island, Kingston, RI. ⁴Aston University, Birmingham, United Kingdom. ⁵Places for People Leisure, London, United Kingdom. ⁶Sheffield Hallam University; GO fit LAB; Universidad Rey Juan Carlos, Madrid, Sheffield, United Kingdom.
 Email: willinger@uni.coventry.ac.uk
 (No relevant relationships reported)

PURPOSE: Physical inactivity is a global health concern, further magnified by gender disparity, with women being less active than men. Gyms may be optimal environments to engage in physical activity, however, perceived gendering describe a major barrier for women to become and stay members. Therefore, our aim was to compare attendance behaviour over the first 12 months and membership length (ML) of female gym members in mixed-gender gyms to a female-only gym, to identify factors explaining both behaviours. **METHODS:** Data from one female-only (n=1,881) and eight mixed-gender gyms (n=21,133 women) across England were analysed, including demographics, membership characteristics, and each member's visits at the gym between 2008-2019. Data were analysed via t-tests and mixed-effect regression analyses using SPSS and R, with significance set at $p=0.05$. **RESULTS:** Women in female-only gyms showed a higher average ML (19.59±21.91 v. 14.30±16.03 months, $p<0.001$) and higher average attendance frequency (4.33±3.29

v. 2.70±3.15 visits/month, $p<0.001$), compared to women in mixed-gender gyms. In female-only gyms, monthly visits and ML were inversely related ($r=-0.441$, $p<0.001$) and the calendar month in which the membership commenced ($r=-0.065$, $p<0.001$), while a higher age increased attendance ($r=0.031$, $p<0.001$) ($R^2=0.147$). An increase in ML was associated with a higher number of membership freezes ($r=3.660$, $p<0.001$), and higher attendance frequency during the 11th ($r=0.619$, $p<0.001$) and 12th ($r=0.598$, $p<0.001$) month of membership ($R^2=0.191$). In mixed-gender gyms, attendance also decreased with ML and increased with age ($r=-0.217$, $p<0.001$ and $r=0.011$, $p<0.001$). A multitude of factors were associated with ML in women in mixed gender gyms, including age ($r=-0.066$, $p<0.001$), attendance frequency during the first month ($r=-0.062$, $p<0.05$), month 11 ($r=0.241$, $p<0.001$) and month 12 ($r=0.400$, $p<0.001$) ($R^2=0.103$). **CONCLUSIONS:** Women in female-only gyms show a higher attendance frequency during the first 12 months and a longer ML than women in mixed-gender gyms. Demographic and membership-related factors only explained a small proportion of the heterogeneity in both outcomes. However, observed R^2 's were higher in female-only gyms, indicating that other factors have a stronger impact on women in mixed-gender gyms.

2200 Board #119 May 28 2:00 PM - 3:30 PM
Lifestyle Risk Factors Associated With Non-Alcoholic Fatty Liver Disease (NAFLD) Among Mexican-Origin Men

David O. Garcia, FACSM¹, Miryoung Lee², Kristin E. Morrill¹, Melissa Lopez-Pentecost¹, Belinda M. Reininger², Joseph B. McCormick², Susan P. Fisher-Hoch². ¹University of Arizona, Tucson, AZ. ²University of Texas Health Science Center at Houston, Brownsville, TX.
 Email: davidogarcia@email.arizona.edu
 (No relevant relationships reported)

Background: Mexican-origin men have the highest rates of non-alcoholic fatty liver disease (NAFLD) among men in the U.S. Current evidence regarding the effects of lifestyle behaviors and risk for NAFLD among Mexican-Origin men is scarce. **Purpose:** To assess the influence of lifestyle behaviors risk for NAFLD, in a sample of Mexican-origin men from the Cameron County Hispanic Cohort (CCHC). **Methods:** The CCHC is a randomly selected cohort of community-dwelling Mexican Americans living in the U.S-Mexico border. Participants completed physical assessments and questionnaires on demographics, medical/medication use history, and lifestyle factors. Liver elastography (FibroScan®) was performed for the assessment of liver steatosis based on controlled attenuation parameters (CAP, dB/m) scores. Survey-based linear regression for CAP score or logistic regression analyses for mild steatosis (CAP \geq 260) were conducted to examine the relationships of lifestyle and cardiometabolic factors to NAFLD. **Results:** 207 Mexican-origin men (mean age: 53.5 (SE 2.5) years; mean BMI: 31.4±0.5. kg/m²; 43.9 % Spanish monolingual; 44.0 % born in U.S.) were included in the analysis. Mean CAP score was 290.4 (SE 7.3) dB/m and the prevalence of steatosis was 66.9% (SE 4.5%). There was no significant relationship of education, marital and uninsured status, smoking history, healthy/unhealthy eating indices, and physical activity levels to steatosis (p -values >0.05). There were significant associations between cardiometabolic risk factors including log transformed glucose OR= 8.20, 95%CI 1.63-41.25, $p=0.0108$), HbA1c (OR=1.43, 95%CI 1.08-1.90, $p=0.013$), HDL-C (OR=0.96, 95%CI 0.93-0.996, $p=0.029$) and log transformed triglyceride levels (OR=7.21, 95%CI 2.58-20.16 $p<0.001$), and steatosis. A one-unit increase in BMI was significantly associated with 36% increase in odds of steatosis (OR=1.36, 95%CI 1.18-1.55, $p<0.001$). Having metabolic syndrome (OR=4.93, 95%CI=1.84-13.19, $p=0.0016$) was significantly associated with steatosis in age- and BMI adjusted models. **Conclusion:** NAFLD was associated with cardiometabolic risk factors among Mexican-origin men in a community-based sample. Efforts to develop health promotion programs to address these risk factors, particularly body weight, are warranted.

2201 Board #120 May 28 2:00 PM - 3:30 PM
The Association Between Hydration And Obesity Is Dependent On How Hydration Status Is Assessed

Alex M. Ehlert, Patrick B. Wilson. Old Dominion University, Norfolk, VA.
 Email: aehle003@odu.edu
 (No relevant relationships reported)

PURPOSE: Several studies have reported obesity is associated with hypohydration at the population level. However, these studies typically used simple urine osmolality thresholds to assess hydration, which may be inappropriate given that the amount of body mass a person has impacts urine solute (creatinine, uric acid) levels. To address this issue, our study compared differences in hypohydration prevalence using common urine methods (osmolality, flow rate, their combination) and examined whether obesity was differentially associated with these measures. **METHODS:** Data of 6,999 adults from the 2009-2012 National Health and Nutrition Examination Survey (NHANES) were analyzed. Hypohydration status was categorized using five thresholds; 1) absolute

urine osmolality (850 mOsm/L), 2) age-specific urine osmolality, 3) urine flow rate (850 mL/day), 4) a combination of absolute urine osmolality and flow rate, and 5) a combination of age-specific urine osmolality and flow rate. Logistic regression was used to examine whether body mass index ≥ 30 kg/m² (vs. less) was associated with the various hypohydration definitions. **RESULTS:** The prevalences of hypohydration were as follows: 21.7% (absolute urine osmolality), 36.8% (age-specific urine osmolality), 37.1% (urine flow rate), 13.0% (absolute urine osmolality and flow rate combined), and 21.1% (age-specific urine osmolality and flow rate combined). Obesity was associated with increased likelihood of hypohydration when using absolute (odds ratio [OR]: 1.63; 95% confidence interval [95CI]: 1.39, 1.92), and age-specific (OR: 1.78; 95CI: 1.48, 2.13) urine osmolality. However, associations were not significant when using urine flow rate (OR: 0.95; 95CI: 0.81, 1.12) or the combination of absolute urine osmolality and flow rate (OR: 1.26; 95CI: 0.98, 1.60). The association was weak, but significant, when using the combination of age-specific urine osmolality and flow rate (OR: 1.29; 95CI: 1.06, 1.58). **CONCLUSIONS:** Common methods used in epidemiological research to assess hydration status result in substantially different prevalences of hypohydration. The association between hypohydration measures and obesity is strongest for urine osmolality measures, though this is perhaps a product of increased urine solutes and not actual differences in hydration.

Predicting Gross Motor Skills In Children: Data From The 2012 NHANES National Youth Fitness Survey

Lindsey E. White, Tiago V. Barreira. Syracuse University, Syracuse, NY.
 (No relevant relationships reported)

Gross motor skills are a key component of childhood development and are characterized by locomotion (movement of the body through space) and object control (manipulation of objects). Collectively, these constructs provide a representation of overall gross motor skill ability. Various factors may influence gross motor skills, specifically measures of fatness and muscular fitness. **PURPOSE:** Determine if measures of fatness, birth weight, and muscular fitness are significant predictors of gross motor skills in children 3-5 years old. **METHODS:** Data from 177 boys and 178 girls from the 2012 National Health and Nutrition Examination Survey National Youth Fitness Survey were used in the analysis. Waist-to-height (WtHR) ratio, sum of skinfolds, and BMI were calculated and used as measures of fatness, birth weight was obtained from parent report, and a timed plank test was used as a proxy measure of fitness. Locomotor (LOC) and object control (OC) skills were evaluated through the Test for Gross Motor Development-2 (TGMD-2). The sums of the standard scores obtained from LOC and OC were then converted to the gross motor quotient which is used as a representation of overall gross motor skill ability. Multiple linear regression models were used with age, standing height, race/ethnicity, and annual household income (AHI) as co-variables. WtHR, sum of skinfolds, BMI, birth weight, and muscular fitness were used as predictor variables. **RESULTS:** After adjustment for age, race/ethnicity, and AHI, birth weight was a significant predictor of the GMQ in young girls ($\beta=1.74$, $p=.044$). In the fully adjusted model, muscular fitness was a significant predictor of the gross motor quotient in both young girls and boys ($\beta=450$, $p<.001$; $\beta=375$, $p<.001$, respectively). **CONCLUSION:** Our results revealed that birth weight was a significant predictor of overall gross motor skill ability in young girls. Additionally, in both young girls and boys, muscular fitness was a significant predictor of overall gross motor skill ability, which further highlights the important role that physical fitness plays on gross motor skills in children. However, the association found between birth weight and gross motor skills is not well known and should be examined further.

A Standardized Model Of Bodyweight Classification For European-american Adults From The 20012006 National Health And Nutrition Examination Survey

Parina Depani, Michael L. Bruneau, Jr. Drexel University, Philadelphia, PA. (Sponsor: Stella Volpe, FACSM)
 (No relevant relationships reported)

BACKGROUND: Obesity is a major public health issue in the United States (US) that affects an estimated 78 million US adults each year. Since the 1970's, obesity rates have more than tripled and have been associated with a higher prevalence of developing cardiometabolic and renal disease. However, body mass index (BMI) alone may be an imprecise measurement of body weight classification as it does not account for either visceral or total body fat. Furthermore, the current fitness categories for body composition are not standardized to the World Health Organization's (WHO) general population guidelines and limit their use in clinical practice.

PURPOSE: To perform a large-scale population-based cross-sectional analysis from the (2001-2006) National Health Assessment and Nutrition Examination Survey (NHANES). **METHODS:** Our population included 12,667 European-American men and women who self-reported their age and sex, and who had complete anthropometric and body composition data from NHANES. Body composition variables included BMI, waist circumference, and total body fat percentage, measured with dual-energy x-ray absorptiometry (DXA). All study participants provided written informed consent prior to enrollment. Descriptive statistics, frequency distributions and percentiles were computed for the total population, and by age, sex and BMI.

RESULTS: Of the included population, 48.8% were men and 51.2% were women. Those with a BMI between 18.0-24.9 kg/m² (normal weight) had a total body fat between 19.6-31.8% and a waist circumference between 64.5-88.0 cm (18th - 54th percentile). Those with a BMI between 25.0-29.9 kg/m² (overweight) had a total body fat between 31.9-39.3% and a waist circumference between 88.1-102.3 cm (55th and 78th percentile). Those with a BMI \geq 30 kg/m² (obese) had a total body fat \geq 39.4% and a waist circumference \geq 102.4 cm (79th - 99th percentile).

CONCLUSIONS: We performed a large-scale population-based cross-sectional analysis from NHANES to standardize metrics of waist circumference and body fat percentage to the WHO's general population guidelines for body weight classification. Our findings may provide healthcare practitioners with a more comprehensive assessment of body composition and serve as a supplemental resource to BMI when determining body weight status for Americans.

Longitudinal Changes Of Kindergarten Children's Physical Fitness In Japan Across Three Years

Kyota Takami¹, Ken'ichi Egawa², Takeru Kato³. ¹Hosei University, Machida, Japan. ²Tokyo Kasei Gakuin University, Tokyo, Japan. ³Asahi University, Mizuho, Japan. (Sponsor: Zan Gao, FACSM)
 Email: k-takami@hosei.ac.jp
 (No relevant relationships reported)

PURPOSE: The physical fitness of Japanese children has shown a downward trend after its peaking after 1985. Because of implementing various fitness programs, it has been increasing since 2007, but it has not yet recovered to the previous level. Bipolarization in fitness has also been identified as a new issue. Therefore, it is imperative to promote efforts that lead to increased children's health and fitness status. The purpose of this study, therefore, was to examine the longitudinal changes in health-related physical fitness to inform future intervention programs aimed at improving children's fitness. **METHODS:** A total of 273 kindergarten children (boys: 138, girls: 135, Mean age = 4.6) were analyzed. Height and weight, and physical fitness (25m run, standing long jump, ball throw, body support continuation time, both feet consecutive jump time, ball catch) were measured for 3 consecutive years. The longitudinal changes were analyzed by paired t-tests. The statistical significance level was 5%. **RESULTS:** All of children's fitness outcomes improved significantly as they aged for both boys and girls. From 3 years old to 4 years old, boys and girls showed significant improvements in 25m run (-2.6+0.2 vs. -1.1+0.1, t=-5.47, p<0.05, -3.0+0.2 vs. -1.0+0.1, t=-8.36, p<0.05) and standing long jump (26.8+2.1 vs. 20.3+1.5, t=2.15, p<0.05, 26.2+1.8 vs. 17.8+1.3, t=3.17, p<0.05). Girls increased in height (6.9+0.1 vs. 6.3+0.1, t=2.92, p<0.05) and improved both feet consecutive jump time (-2.1+0.3 vs. -1.2+0.2, t=-2.64, p<0.05). From 4 to 5 years old, the boys' ball throw and body support continuation time improved significantly. Yet, there was no differences in the amount of changes in weight and ball catch between boys and girls. **CONCLUSION:** Children's fitness in early childhood was highly correlated with physical development. However, the time of improvement was quite different. Therefore, although it is not necessary to train children based on physical fitness factors, we may consider age and gender differences in physical fitness while planning intervention programs in kindergarten children.

The Influence Of Weather Conditions, Ambient Air Temperature On Sedentary Time In Chinese Adults

xu wen. Zhejiang University, Hangzhou, China.
 Email: wenxu@zju.edu.cn
 (No relevant relationships reported)

PURPOSE: This study aimed to quantify the association between weather conditions, ambient air temperature and sedentary time in Chinese adults.

METHODS: The participants were 3270 Chinese users of a wrist-worn activity tracker. The data of participants' daily activities were collected from July to October 2015 in 33 out of 34 provinces, autonomous regions and municipalities in China. The inclusion standards for data analysis were set as: 1) aged 18 or above; 2) without disability and critical diseases; 3) wear time \geq 18 h per day and \geq 4 consecutive days; 4) Global Positioning System (GPS) data are available; 5) meteorological data are available. Two-level linear regression analyses were conducted to investigate the association between weather condition, ambient air temperature and sedentary time.

RESULTS: The results of two-level linear regression analyses showed that weather conditions had a significant but weak influence on sedentary time in Chinese adults after adjusting for some covariates. If the weather condition changes from rainy days to sunny days and cloudy days, sedentary time may decrease by about 6.89 minutes (95%CI: 11.45-2.34) and 5.60 minutes (95%CI: 9.33-1.86) respectively. The sedentary time would decrease by 6.12 minutes (95%CI: 9.33-1.86) if air temperature changed from \geq 25°C to < 22.1-24.9°C. However, the influence was not significant if gender, air quality and weather condition was adjusted.

CONCLUSIONS: In conclusion, weather conditions have significantly but weakly influence on sedentary time in Chinese adults. Compared with the rainy days, the daily sedentary time was shorter in sunny and cloudy days. When other environmental and individual factors were adjusted, no significant association between ambient air temperature and sedentary time was found.

2207 Board #126 May 28 2:00 PM - 3:30 PM
Prevalence And Risk Factors For Premenstrual Syndrome In Korean Female National Athletes

Taeim Yi¹, MunJung Bae². ¹Yongin Severance Hospital, Yonsei University College of Medicine, Yongin city, Korea, Republic of. ²Korean Sports & Olympic Committee, Jincheon city, Korea, Republic of.
 Email: taeim@yuhs.ac
 (No relevant relationships reported)

Premenstrual syndrome is common in female athletes, and related symptoms, such as anxiety, anxiety, breast tenderness, and bloating, can negatively affect performance. However, there are very few studies on premenstrual syndrome in female athletes worldwide. A survey of PMS is needed to provide proper medical support and to improve performance. **Purpose :** The purpose of this study was to investigate the prevalence of premenstrual syndrome and related risk factors in elite female athletes. **Methods :** A survey about premenstrual syndrome was conducted among female athletes training at national training centers. Premenstrual syndrome was diagnosed using the Premenstrual Symptom Screening Tool (PSST). Mann-Whitney test was performed to determine differences in age, training time, and body mass index (BMI) according to premenstrual syndrome. The chi-square test was performed to investigate differences in alcohol and coffee intake, diet for weight loss, stress fracture, and menstrual regularity according to premenstrual syndrome. **Results :** The average age of 124 female athletes across 17 sports was 24.36 (\pm 4.68) years, and the mean BMI was 22.19 (\pm 3.81). Of the 124 patients, 17 met criteria for moderate to severe PMS, and one met the criteria for premenstrual discomfort. Athletes diagnosed with moderate to severe PMS complained of fatigue (100%), irritability (78%), difficulty concentrating (78%), joint and muscle pain (56%), bloating (56%), and weight gain (56%). Age, type of sport, BMI, training time per week, menarche age, and coffee and alcohol consumption were not significantly related to the prevalence of premenstrual syndrome. Overall, 76.6% of the female athletes felt that premenstrual symptoms interfered with their performance; however, only five out of the 18 athletes with moderate to severe PMS visited their doctors to discuss it. **Conclusions :** This cross-sectional study of the prevalence of and risk factors for premenstrual syndrome in Korean female athletes found that 18 (14.55%) of 124 athletes had moderate to severe PMS, and no risk factors for developing premenstrual syndrome were discovered.

2208 Board #127 May 28 2:00 PM - 3:30 PM
Levels And Patterns Of Physical Activity And Sedentary Time Among Low Income Brazilian Preschoolers

Jorge Mota¹, Taís Feitosa da Silva², Clarice Lucena Martins³. ¹Research Centre in Physical Activity Health and Leisure, Porto, Portugal. ²Universidade Federal da Paraíba, João Pessoa, Brazil. ³Universidade Federal da Paraíba, João Pessoa, Brazil.
 Email: jmota@fade.up.pt
 (No relevant relationships reported)

Knowledge of physical activity in preschool populations is important for public health promotion. However, little is known about physical activity and sedentary patterns in low-income children, suggesting an urgent need for data covering this population. Purpose: to describe physical activity levels and sedentary time of low-income preschool children during preschool time; to describe physical activity patterns of actives during preschool time at public preschools in João Pessoa/Brazil. Method: a representative sample of 237 preschool was randomly selected and 204 provided valid accelerometer measurements (boys: 4.5 \pm 0.8years, girls: 4.5 \pm 0.7years). Measured levels of physical activity and sedentary time, and physical activity patterns were observed during preschool time (7am to 5pm) (Actigraph, WGT3-X). Data were presented in quartiles of total physical activity by sex and age. Univariate General Linear Model with Bonferroni's post-hoc was used to analyze differences between the quartiles. Data were performed using SPSS (version 25, Inc., Chicago, USA), level of significance: 95%. Results: physical activity at preschool range from 68 to 114% of total physical activity daily's recommendation and from 28 to 83% of moderate

to vigorous physical activity recommendation. For the two most active quartiles, the daily total physical activity recommendation was achieved during preschool time. Physical activity patterns were similar between the least and the highest actives, and all the evaluated children were more active outdoors than indoors. For the least actives, preschool time correspond 30% of daily moderate to vigorous physical activity recommendation. Physical activity patterns are quite similar between the least and the highest actives. Conclusion: this information is important for tailoring interventions.

The Effects Of High Molecular Weight Carbohydrate Supplementation On Skeletal Muscle Performance

T. Brock Symons¹, Franklin Muntis², Tom Collins², Keith Gworek², Kathleen A. Carter, FACSM³, John F. Caruso². ¹Texas A&M University - San Antonio, San Antonio, TX. ²University of Louisville, Louisville, KY. ³Central State University, Wilberforce, OH.

(No relevant relationships reported)

Athletes continue to seek new and improved strategies to preserve skeletal muscle strength and attenuate effects of skeletal muscle fatigue during resistance training. The ingestion of carbohydrates prior-to and during resistance training was hypothesized to improve both skeletal muscle performance and attenuate fatigue. VitargoS2™ is a high molecular weight carbohydrate supplement that promotes enhanced performance with its consumption prior-to and during physical activity. **PURPOSE:** To examine the influence of high molecular weight carbohydrate (HMC) consumption on skeletal muscle performance and fatigue following exhaustive lower-limb resistance training exercise. **METHODS:** Five-female and seven-male (n = 12) healthy college-aged individuals participated (26.1 ± 3.8 yrs) in a double-blinded crossover trial. Participants took part in three sessions across the study period: familiarization, Test Day 1 and Test Day 2. Participants were randomly assigned to one of two conditions [control (CON) or high molecular weight carbohydrate supplement (HMC)] for each of the two testing sessions. Lower-limb isometric and isokinetic concentric strength was assessed prior-to and immediately following a resistance-training session on two occasions. Outcome measures included lower-limb isometric and isokinetic concentric peak torque, blood glucose concentration, and rate of perceived exertion (RPE). **RESULTS:** The HMC condition elicited a significant increase in blood glucose concentration from Pre-Workout to Post-Workout (Pre-Workout: 92.1 ± 14.4 mg/dl and Post-Workout: 118.3 ± 15.2 mg/dl) compared to the control condition (Pre-Workout: 95.6 ± 15.6 mg/dl and Post-Workout: 108.1 ± 14.5 mg/dl). Isometric strength was reduced by 25.4 Nm (HMC) and 35.0 Nm (CON) following the lower-limb resistance training session; however, no ergogenic effect was found (p > 0.05). Isokinetic concentric strength did not differ (p > 0.05) following the HMC supplementation compared to the CON condition. No difference was found in RPE between the HMC and CON condition (p > 0.05). **CONCLUSIONS:** The consumption of HMC supplementation prior to and during resistance-training exercise did not improve skeletal muscle performance and attenuated skeletal muscle fatigue following a lower-limb resistance-training exercise session.

Effect Of Pre-Sleep Low Glycemic Modified Starch On Morning Metabolism And Endurance Running Performance

Monique D. Dudar¹, Emilie D. Bode¹, Karly R. Fishkin¹, Rochelle A. Brown¹, Madeleine M. Carré¹, Noa R. Mills¹, Michael J. Ormsbee, FACSM², Stephen J. Ives¹. ¹Skidmore College, Saratoga Springs, NY. ²Florida State University, Tallahassee, FL. (Sponsor: Michael J. Ormsbee, FACSM)

(No relevant relationships reported)

Consumption of carbohydrates (CHO) likely influences athletic performance, and further evidence suggests that pre-sleep nutrition may positively affect subsequent morning physiologic responses and exercise performance. **PURPOSE:** To determine the effects of pre-sleep ingestion of a novel low glycemic index (LGI) CHO supplement on next morning endurance running performance, substrate utilization,

and gastrointestinal distress (GID). **METHODS:** Using a double-blind, randomized, crossover design, 14 endurance athletes (age, 28 ± 9 yrs; peak oxygen consumption (VO_{2peak}), 55 ± 7 ml/kg/min) consumed either a high GI (HGI), LGI, or placebo (PLA) beverage ~30 min prior to sleep and 7-9hrs before a morning exercise trial. Resting energy expenditure (REE), gas exchange derived substrate utilization (%FAT, %CHO), blood glucose (BG), heart rate (HR), satiety (SAT), and GID were assessed at baseline. After a warmup, an incremental exercise trial (IET) was performed at 55, 65, and 75% VO_{2peak}, while HR, GID, rating of perceived exertion (RPE), and substrate utilization were obtained. After a 3-min recovery, participants completed a 5km treadmill time trial (TT), during which HR, RPE, and GID were recorded. HR, RPE, GID, satiety, and BG were assessed immediately post TT, and BG was recorded again 10min post TT. **RESULTS:** No differences were found in baseline REE, BG, GID, HR, or SAT (all, p > 0.05). At rest, there was an interaction of supplement and sex for substrate utilization (CHO and FAT, p < 0.05). During IET, LGI tended to utilize less FAT (HGI, 40 ± 12, PLA, 44 ± 11, LGI, 38 ± 11%FAT, p = 0.06) and more CHO (HGI, 60 ± 12, PLA, 56 ± 11, LGI, 63 ± 12%CHO, p = 0.08). There was no effect of condition on GID at any point (p > 0.05). There was no effect of condition on 5km TT (PLA, 21.6 ± 9.6; HGI, 23.0 ± 7.8; LGI, 24.1 ± 4.5 min, p > 0.05). **CONCLUSIONS:** The current study demonstrates that pre-sleep CHO supplementation did not affect resting substrate utilization, BG, GID, or 5km TT performance, though effects on substrate utilization might be sex specific. The trend towards higher CHO utilization after pre-sleep LGI CHO consumption might suggest that pre-sleep LGI CHO supplementation increases morning CHO availability, though more research is needed.

Carbohydrate Before Resistance Exercise Doesn't Alter Performance, Blood Glucose, Or Muscle Glycogen Despite Hormonal Changes

Dylan Wilburn, Steven Macheck, Thomas Cardaci, Paul Hwang, Darryn Willoughby, FACSM. Baylor University, Waco, TX. (Sponsor: Dr. Darryn Willoughby, FACSM)

Email: dylan_wilburn1@baylor.edu

(No relevant relationships reported)

Purpose: The purpose of this study was to investigate changes in resistance exercise performance, serum insulin, epinephrine, glucose, and muscle glycogen from carbohydrate supplementation. **Methods:** Participants completed four sets to failure at 70% of 1-RM with 45s rest on angled leg press with or without pre-exercise carbohydrate (2g/kg) after a 3hr fast. Serum glucose, epinephrine, and insulin were assessed at baseline, 30 min post-ingestion, immediately after, and 1hr post-exercise with or without carbohydrate supplementation. Muscle glycogen was measured at baseline, immediately after exercise, and 1hr post exercise. **Results:** There was no main effect of supplement on resistance exercise performance (F = 2.169, p = .18). There was a main effect for set on repetitions showing a decrease over sets completed (F = 26.18, p < .001) There was no interaction between supplement and set on reps to fatigue (F = .337, p = .79). There was a time effect showing glycogen decreased immediately post-exercise for both groups and remained lower than baseline after 1hr (F = 14.305, p < .001). No main effect of supplement on glycogen concentration was found (F = 2.847, p = .13). No supplement time interaction was found on glycogen (F = 1.191, p = .33). There was an interaction showing pre-exercise carbohydrate supplementation led serum glucose to be utilized more during exercise (F = 3.791, p = .026). No main effect for supplementation on blood glucose was found (F = .072, p = .79). Pairwise comparisons indicated no time effect on serum glucose (p > .05). An interaction occurred showing insulin decreased during exercise in the carbohydrate condition (F = 47.14, p = .003). Also, there was a main effect of insulin being elevated with carbohydrate consumption (F = 7.72, p = .027). Pairwise comparisons indicated there was no time effect on insulin concentration (p > .05). There was a main effect of carbohydrate supplement decreasing epinephrine (F = 7.924, p = .023). No time effect was found on epinephrine concentration (F = 1.475, p = .258). No interaction effect was found on epinephrine (F = 1.94, p = .181). **Conclusions:** Carbohydrate supplementation before resistance exercise does not improve leg press performance to fatigue or glycogen recovery during 1hr rest despite increased glucose availability.

2213 Board #132 May 28 3:00 PM - 4:30 PM
Effect Of Different Glycemic Index Beverage On Substrate Oxidation During Moderate Intensity Exercise.

xintang wang, Qing Yuan, Longyan Yi, Haiqing Tong. Beijing Sport University, Beijing, China.

Email: wangxintang@bsu.edu.cn

(No relevant relationships reported)

PURPOSE: To investigate the effect of low or high glycemic index (GI) beverage on substrate utilization during moderate intensity exercise. **METHODS:** This research design utilized a randomized and counterbalanced crossover approach with ten male participants (Age: 24.6 ± 0.8 yr; BMI: 22.8 ± 1.3 kg/m²;

) engaged in three times (separated by 1 week) of 1-hour ergometer cycling (Monark 839E, Sweden) at 60% $\dot{V}O_{2max}$ intensity while ingesting two types of beverages with different GI values (LGI=47, HGI=90), and water only. Carbohydrate intake was set at 0.2g/kg every 15 minutes, and blood samples were collected pre-exercise and 0h-, 1h-, 2h-post-exercise for glucose, insulin, free fatty acid (FFA) and triglyceride analyzing. Substrate utilization was measured using metabolic cart (Cortex MetaLyzerII-R2, Germany) at 5min, 30min, 50min during exercise.

RESULTS: There was no significant difference of carbohydrate oxidation rate between LGI and HGI beverage treatment ($p=0.36$). Fat oxidation rate was significantly higher in LGI (0.22 ± 0.08 g/min) compared to HGI treatment (0.18 ± 0.07 g/min) and water (0.16 ± 0.06 g/min) at 30 minutes during exercise ($P<0.05$). Blood glucose concentration was higher in HGI (5.64 ± 0.72 mmol/L) and LGI (5.35 ± 1.06 mmol/L) compared with water treatment (4.82 ± 0.76 mmol/L) 0h-post-exercise ($P<0.05$). Plasma insulin concentration in HGI treatment increased significantly 1h-post-exercise ($15.11\pm 5.94\mu\text{U/mL}$) compared with LGI ($9.64\pm 2.10\mu\text{U/mL}$) and water ($3.53\pm 1.22\mu\text{U/mL}$) ($P<0.05$). Plasma triglyceride (0.97 ± 0.30 mmol/L) and FFA (0.48 ± 0.18 mmol/L) concentration were lower in LGI treatment compared to water treatment 0h-post-exercise ($P<0.05$), but not in HGI treatment ($P>0.05$).

CONCLUSIONS: Compared with HGI beverage before and during exercise supplementation, LGI beverage consumption may elevated fat substrate utilization during moderate intensity exercise.

Effects Of Carbohydrate-Electrolyte Solution Supplementation On Fluid Retention And Aerobic Capacity After Exhaustive Exercise

Ming-Ta Yang¹, Chang-Ti Huang¹, Mai-Szu Wu², Ming-Che Liu³, Sy-Jye Leu¹. ¹Taipei Medical University, Taipei, Taiwan. ²Taipei Medical University-Shuang Ho Hospital, New Taipei, Taiwan. ³Taipei Medical University Hospital, Taipei, Taiwan. Email: yangrugby@gmail.com
 (No relevant relationships reported)

Rehydration, or restoration of fluid spaces, is important when exhaustive endurance exercise (EEE) has compromised hydration status. Previous studies only investigated the effects of carbohydrate-electrolyte solution (CE) supplementation to facilitate replacement after exercise induced dehydration. CE supplementation for 1 hour before and 1 hour after EEE may play an important role in fluid retention and enhancing aerobic capacity.

PURPOSE: To examine the effects of CE supplementation on fluid retention and aerobic capacity after EEE.

METHODS: In a double-blind, crossover and counterbalanced designed study, nineteen health male participants were asked to intake ORS-SH[®], an oral rehydration solution, (150 mL four times within an hour) or placebo (water) for 1 hour before and 1 hour after EEE. All participants completed graded exercise test to exhaustion on treadmill for determination of maximal oxygen consumption ($\dot{V}O_{2max}$) before supplementation, and then completed the exhaustive endurance exercise test at the intensity of 70% $\dot{V}O_{2max}$ for 60 min. Then, the exercise intensity increased at 90% $\dot{V}O_{2max}$ until exhaustion after supplementation. The average heart rate, maximal heart rate, running time to exhaustion and peak oxygen uptake were recorded during the exercise period. The body weight was recorded 15-min, 30-min, 45-min and 60-min of after EEE to calculate the dehydration rate and beverage hydration index (BHI).

RESULTS: The dehydration rates in participants with ORS-SH[®] treatment at 15-min, 30-min and 45-min of after EEE were significantly lower than with placebo treatment ($-1.77\pm 0.50\%$ vs. $-2.06\pm 0.66\%$; $-1.69\pm 0.54\%$ vs. $-1.95\pm 0.66\%$; $-1.48\pm 0.51\%$ vs. $-1.76\pm 0.65\%$, respectively, $p < .05$). In addition, the BHI in participants with ORS-SH[®] treatment at 15-min, 30-min and 45-min of after EEE (1.19 ± 0.36 , 1.22 ± 0.43 and 1.27 ± 0.54) were significantly higher than with placebo treatment ($p < .05$). However, there were no significant differences in other variables between treatments.

CONCLUSIONS: ORS-SH[®] supplementation can effectively enhance fluid retention after EEE. However, ORS-SH[®] supplementation had no benefits on aerobic capacity. Supported by Panion & BF Biotech Inc. (Grant No: A-107-077)

Effects Of Repeated Carbohydrate Rinse On Lacrosse Performance

Austin T. Streeter, Joshua C. Wehn, Andrew J. Carnes, Sara E. Mahoney, FACSM. *Bellarmine University, Louisville, KY.* (Sponsor: Sara E Mahoney, FACSM)
 (No relevant relationships reported)

While carbohydrate rinse has been demonstrated to be an effective strategy for improving endurance performance, the effects of rinse on anaerobic performance, particularly within team sport athletes, are equivocal. Additionally, it is not yet known whether repeated carbohydrate rinses in the context of a high intensity training session may provide additional benefit. **PURPOSE:** The purpose of this investigation was to determine the effect of repeated carbohydrate rinse during a typical lacrosse

team practice on lacrosse performance. **METHODS:** A randomized, double-blind, placebo-controlled design was used to determine the effects of carbohydrate rinse on 11 male, division I lacrosse players. Shot velocity and accuracy, 40-yard dash time, and concentration (measured via Trail Making Test) were assessed prior to a typical practice, and the test battery was completed again following practice on two subsequent days of similar intensity/duration. During both practice sessions, the athletes completed 4 rinses (carbohydrate- CHO or placebo-PLA), equally spaced throughout the session, and practice intensity was measured using RPE and HR. Changes from pre-post were calculated for each test and paired t-tests were used to determine differences between groups. **RESULTS:** Shot velocity and accuracy were significantly reduced following practice, however the reduction in shot accuracy was blunted in the CHO v. PLA ($9.01\%\pm 14.4$ v. $19.49\%\pm 21.7$, $p = 0.01$). 40-yard dash was not significantly reduced by the training session, and no differences were detected between groups (CHO: 5.057 ± 0.25 sec v PLA 5.051 ± 0.27 sec). RPE was significantly lower for CHO (9.90 ± 3.41 v. 12.72 ± 2.76 , $p=0.04$) at timepoint 2, but not at any other time. Changes in TMT following practice were not significantly different between groups. **CONCLUSION:** When used during a typical lacrosse practice, repeated carbohydrate rinse may reduce the effects of fatigue on shot accuracy and perceived exertion, however it does not appear to effect other performance measures.

Glucose Mouth Rinse And Mouth Spray Enhance Prolonged Exercise Performance In Healthy Male College Students

Tsuyoshi Wadazumi¹, Kanji Watanabe², Hitoshi Watanabe³, Hisayo Yokoyama³, Nobuko Hongu, FACSM⁴. ¹Kansai University, Sakai-shi, Japan. ²Mukogawa Womes s University, Nishinomiya, Japan. ³Osaka City University, Osaka-shi, Japan. ⁴University of Arizona, Tucson, AZ. (Sponsor: Nobuko Hongu, FACSM)
 Email: wadazumi@kansai-u.ac.jp
 (No relevant relationships reported)

PURPOSE: Research supports the ergogenic effects of glucose mouth rinse (GMR) during prolonged performance, however, the effects of glucose mouth spray (GMS) is limited. The aim of this study was to investigate the effects of GMR and GMS on prolonged exercise. **METHODS:** Nine male college students (age, 22.2 ± 1.1 years; height, 172.0 ± 4.7 cm; body weight, 66.4 ± 6.1 kg; $\dot{V}O_{2peak}$, 3014.9 ± 251.6 ml/min) performed constant load exercise using an electromagnetic brake-type bicycle ergometer (PowerMax VIII; Combi Wellness, Japan). The participants performed constant load exercise for 60 min (intensity 40% $\dot{V}O_{2max}$) and then, four sets of the Wingate test (three 30-s Wingate tests with 4 min recovery period between each test) while they were performing constant load exercise for 30 min (intensity 40% $\dot{V}O_{2max}$). Each trial lasts for 4.8 hrs. All participants completed a total of four experimental trials: (1) ingesting glucose (G) solution (500 ml) at the beginning, (2) 15 GMR, (3) 15 GMS - 5 times rinse or spray during each 30 min constant load, and (4) water (control) ad libitum during the entire trial. The exercise max power value, blood glucose levels, and rating of perceived exertion, were measured. Repeated two-way analysis of variance (ANOVA) was used for comparison of the data among G, GMR, GMS and water. **RESULTS:** The % value of the average max power at the 3rd and 4th sets for each trial (G, GMR, and GMS) were significantly higher compared to the control (water): 3rd set; $95.0\pm 1.5\%$, $96.9\pm 1.5\%$, $96.5\pm 1.4\%$, and $90.2\pm 1.5\%$ (control), $p < 0.01$, respectively, and 4th set; $89.8\pm 1.5\%$, $92.8\pm 1.5\%$, $92.9\pm 1.5\%$, and $85.1\pm 1.5\%$ (control), $p < 0.01$, respectively. Blood glucose level at the 3rd and 4th sets of G, GMR, GMS were significantly higher compared to the control: 3rd set; 80.7 ± 4.5 mg/dl, 81.4 ± 2.5 mg/dl, and 78.3 ± 2.9 mg/dl, 71.3 ± 3.7 mg/dl (control), $p < 0.05$, respectively, and 4th set; 81.8 ± 5.9 mg/dl, 81.4 ± 2.5 mg/dl, 78.3 ± 2.9 mg/dl, and 71.0 ± 2.8 mg/d (control), $p < 0.01$, respectively. During the 3rd and 4th sets, all G, GMR and GMS showed significantly lower rating of perceived exertion compared to water (control), $p < 0.05$. **CONCLUSION:** GMR and GMS resulted in improved endurance performance. The role of G receptors in the mouth during prolonged exercise warrants further investigation.

A 16% Carbohydrate-hydrogel Beverage Reduces Gastrointestinal Permeability And Enterocyte Damage After Cycling In Hot-humid Conditions

Ben J. Lee¹, Stefano Montanari¹, Marley Wicks¹, Jack Blanchard¹, Matthew R. Kuennen², Lee Taylor, FACSM³, Tessa R. Flood¹. ¹University of Chichester, Chichester, United Kingdom. ²High Point University, High Point, NC. ³Loughborough University, Loughborough, United Kingdom.
 Email: b.lee@chi.ac.uk

(No relevant relationships reported)

Background. Carbohydrate ingestion during exertional heat stress can reduce enterocyte damage and preserve gastrointestinal permeability. Athletes have begun to use drinks which encapsulate carbohydrate within a pectin-alginate hydrogel, yet little evidence exists to support their preferential use versus traditional carbohydrate-gels and/or beverages with multiple transportable carbohydrates. **Purpose.** To compare the effects of consuming a 16% carbohydrate-hydrogel drink to a nutrient matched maltodextrin-fructose (MF) drink on enterocyte damage and gastrointestinal permeability after cycling in hot and humid conditions. **Methods.** Fourteen endurance trained cyclists (7 men, age 27 ± 8 yr, 176 ± 10 cm, 74 ± 11 kg, $\dot{V}O_{2max}$: 55.2 ± 9.5 ml·kg⁻¹·min⁻¹) cycled (45% $\dot{V}O_{2max}$) for 90 minutes before completing a 15-minute time trial in hot humid conditions (32°C, 70%) on 3 occasions separated by 7 days. During trials participants consumed either water (W), a traditional MF drink, or an encapsulated carbohydrate hydrogel drink (HYDRO) in a randomised order. Each CHO drink provided 90 g CHO·hr (16% w/v). Twenty minutes into exercise a 50 mL drink containing lactulose (L; 5 g) and rhamnose (R; 2 g) was provided and intestinal permeability determined by the percent ratio of lactulose to rhamnose recovered in post exercise urine samples. Venous blood samples were obtained before and 5 minutes after the time trial for assessment of intestinal fatty acid binding protein (IFABP), and data analysed using mixed linear models with fixed effects for condition (W/MF/HYDRO) and time (before and after exercise). **Results.** L:R was greatest in W, and lower in both HYDRO [by 0.019 (95% CI: 0.010 to 0.027), p = 0.0003], and GF [by 0.014 (95% CI: 0.006 to 0.022), p = 0.0018]. No differences in L:R were found between the H and GF conditions (p = 0.083). Post-exercise IFABP concentrations were greater in W compared to HYDRO [by 349 pg·mL⁻¹ (95% CI: 137 to 561 pg·mL⁻¹), p = 0.007] and GF [by 427 pg·mL⁻¹ (95% CI: 152 to 701 pg·mL⁻¹), p = 0.018]. There was no difference in post exercise IFABP concentrations between H and GF (p = 0.90). **Conclusion.** Both CHO drinks preserved intestinal permeability and reduced the appearance of circulating IFABP compared to W. HYDRO offered no additional benefit beyond those achieved with a traditional MF drink.

Effects Of Weight Regain In Obese Individuals With Nafld Following A Low Carbohydrate Diet

Erik Kirk, FACSM¹, Dominic Reeds², Samuel Klein². ¹Southern Illinois University Edwardsville, Edwardsville, IL. ²Washington University School of Medicine, Saint Louis, MO.
 Email: ekirk@siue.edu

(No relevant relationships reported)

PURPOSE: We determined the effects of weight regain in individuals with NAFLD following a low carbohydrate diet (LC). **METHODS:** Twelve obese subjects (body-mass index, 36.5 ± 1.0 kg/m²) with NAFLD (10.3 ± 2.8%) followed a LC (<60g/d) energy-deficit diet (1,200kcal/day) for 12 weeks. Participants were followed-up at 9 months after the end of the weight loss (WL) phase. DXA, Magnetic resonance spectroscopy, muscle biopsies, and a euglycemic-hyperinsulinemic clamp were used to determine body composition, intrahepatic triglyceride content (IHTG), and insulin action before, after ~12 weeks of caloric restriction using a LC diet, and 9 months follow-up (post weight loss). **RESULTS:** Participants lost a significant (p<0.05) amount of body weight from baseline (101.9 ± 4.0kg) to 12 weeks WL (93.4 ± 4.0kg) but regained most of the body weight body at 9 months follow-up (97.5 ± 5.5kg, p>0.05 compared to baseline). IHTG significantly (p<0.05) decreased from baseline (12.4 ± 2.9%) to 12-weeks WL (8.9 ± 7.3%) but returned to baseline values at 9 months follow-up (11.5 ± 8.9%, p>0.05 compared to baseline). Basal glucose rate of appearance significantly decreased from baseline (14.2 ± 0.4 μmol/kgFFM/min, p<0.001) to WL (11.7 ± 0.3 μmol/kgFFM/min) but returned to baseline values at 9 months follow up (13.2 ± 1.5 μmol/kgFFM/min, p>0.05 compared to baseline). Homeostasis model assessment (HOMA-IR) significantly (p<0.01) decreased from baseline (4.9 ± 0.7) to WL (2.7 ± 0.5) but returned to baseline values at 9 months follow up (4.6 ± 1.6, p>0.05 compared to baseline). **CONCLUSIONS:** Weight regain results in the metabolic profile of obese individuals with NAFLD to return to pre-weight loss levels; emphasizing the need for effective approaches to prevent weight regain following clinically significant weight loss.

Effects Of Low-carbohydrate And Caloric Restriction Diets On Mental Status And Physical Performance

Koichi Okita¹, Tomofumi Taniura¹, Shingo Takada¹, Noriteru Morita². ¹Hokusho University, Ebetsu, Japan. ²Hokkaido University of Education, Iwamizawa, Japan.

Email: okitak@hokusho-u.ac.jp

(No relevant relationships reported)

Low-carbohydrate diets (LCD) for weight reduction and the management of the metabolic syndrome are increasingly popular, but there is a paucity of research about the negative effects of LCD on mental status and physical fitness. **PURPOSE:** We examined the effects of LCD vs. caloric restriction on mental status and physical performance in untrained subjects with overweight and/or glucose intolerance. **METHODS:** We recruited 24 sedentary young subjects (20 ± 2 yrs) and randomly assigned them to an LCD group (carbohydrate intake <40 g) and a caloric restriction (CR) diet group (ideal weight × kcal). We measured the subjects' body composition, blood metabolic parameters (fasting glucose, insulin, lipids, uric acid, liver enzymes, ketone bodies, C-reactive protein, adiponectin, growth hormone, testosterone and dehydroepiandrosterone), mental status (State-Trait Anxiety Inventory [STAI] and brain-derived neurotrophic factor) and various physical performance aspects (leg extension, handgrip dynamometry, sit-up, and bicycle ergometer) before and after 1 month of the diets. **RESULTS:** The ketone bodies value rose remarkably in the LCD group from before the diet to 1 month on the diet (64.9 ± 33.0 vs. 962.1 ± 1047.0 μmol/L, p=0.017) but was unchanged in the CR group (64.8 ± 10.2 vs. 239.0 ± 336.9 μmol/L, p=0.107). The body mass index decreased significantly in both the LCD (24.9 ± 3.5 vs. 23.5 ± 3.5 kg/m², p<0.001) and CR (24.7 ± 3.8 vs. 24.1 ± 3.8 kg/m², p=0.026) groups. Waist circumference significantly decreased in the LCD group (84.9 ± 3.5 vs. 81.1 ± 10.2 cm, p=0.001) but did not change significantly in the CR group (83.8 ± 12.0 vs. 82.6 ± 11.8 cm, p=0.145). The physical performance aspects were similarly maintained in both groups. Other blood parameters and the mental status did not change significantly in either group. **CONCLUSIONS:** Our results demonstrated that an LCD for a relatively short term can decrease obesity measures more effectively than caloric restriction, without negative effects on mental status or physical performance.

Short-term Caloric Restriction With Low Carbohydrate Intake Augmented Baseline Hepcidin Level In Young Females

Nanako Hayashi¹, Ayame Iwata¹, Haruka Yatsutani¹, Aya Ishibashi², Kazushige Goto¹. ¹Ritsumeikan University, Shiga, Japan. ²Japan Institute of Sports Sciences, Tokyo, Japan.

(Sponsor: Takeshi Hashimoto, FACSM)

Email: sh0108hx@ed.ritsumei.ac.jp

(No relevant relationships reported)

Hepcidin is a liver-derived hormone to attenuate iron metabolism. Recent studies suggest that negative energy balance promotes hepcidin elevation. **PURPOSE:** The purpose of the present study was to examine the effect of caloric restriction (CR) with low carbohydrate intake on hepcidin responses. **METHODS:** Twenty-two young females (age: 21.2 ± 0.2 yrs, body weight: 54.6 ± 1.3 kg) were divided into two different groups, either CR with low carbohydrate intake group (LCHO; 22%PRO, 39%FAT, 39%CHO, 1123kcal) or CR with neutral carbohydrate intake group (NCHO; 18%PRO, 19%FAT, 63%CHO, 1162kcal). During three consecutive days of CR program, subjects consumed only the prescribed diet and maintained their usual physical activity levels. Before and after intervention, body composition, basal hepcidin levels or iron status were evaluated following the overnight fast. Six subjects (LCHO: n = 3, NCHO: n = 3) were excluded from data analysis due to severe iron deficiency (serum ferritin < 10 ng/mL) or infection. **RESULTS:** After intervention, body weight and fat mass were significantly decreased (P < 0.05), with no significant difference between groups. Following the intervention, blood glucose level significantly decreased in LCHO group (P < 0.05). Serum iron and ferritin levels were significantly elevated following the intervention (P < 0.05). Moreover, the magnitude of increased serum iron level tended to be higher in LCHO group than in NCHO group (P = 0.06). In contrast, total iron-binding capacity (TIBC) did not differ following the intervention in either group. Also, plasma IL-6 level did not change following the intervention (LCHO: before 0.84 ± 0.14 pg/mL, after 0.66 ± 0.06 pg/mL, NCHO: before 1.09 ± 0.23 pg/mL, after 0.93 ± 0.19 pg/mL). Serum hepcidin level significantly increased after the intervention in both groups (LCHO: before 13.11 ± 4.16 ng/mL, after 29.9 ± 4.76 ng/mL, NCHO: before 13.03 ± 3.10 ng/mL, after 19.94 ± 4.41 ng/mL, P < 0.05). In addition, the relative change in hepcidin level was significantly higher in LCHO group (264.3 ± 87.2%) than in NCHO (68.9 ± 22.1%, P < 0.05). **CONCLUSIONS:** Three consecutive days of CR with low carbohydrate intake augmented basal hepcidin level compared with CR with neutral carbohydrate intake. Long Term Habituation To Carbohydrate-Restricted Diet Preserved Performance And Central Drive After 2 Hours Of Running: A Case Study

Beth W. Glace, Ian J. Kremenec, Malachy P. McHugh, FACSM. *Nicholas Inst. of Sports Med. and Athletic Trauma, Lenox Hill Hosp., New York, NY.* (Sponsor: Malachy P McHugh, FACSM)
 Email: lb@nismat.org
 (No relevant relationships reported)

PURPOSE: While the brain is usually wholly dependent on glucose for fuel, prolonged carbohydrate deprivation results in adaptations that allow the brain to access fat via ketone bodies. Given the depletion of carbohydrate that takes place during prolonged exercise, a shift toward ketone bodies may maintain central nervous system function, preventing the central fatigue observed during long-duration exercise. In addition, enhancing peripheral muscle's use of free fatty acids and intra-muscular lipids might prolong contractions. Thus, high fat/low carb diets have been proposed to delay fatigue during endurance exercise. However, studies utilizing periods of 1 to 5 weeks of adaptation to high fat diets have shown equivocal changes in performance at moderate or high intensities. We compare endurance and time trial performance of a keto-adapted male runner (KETO) to 8 subjects (NORM) on whom we have previously reported.

METHODS: We measured peripheral and central fatigue in 8 men runners (38±2 yrs; VO_{2peak} 59±3 ml/kg/min) who habitually ate a carbohydrate-liberal diet (NORM) and in a runner (41 yrs, 70 ml/kg/min) who followed a high fat/low carb diet for >2 years. Water was provided at 1% of body mass/hr, during a 2-hr run at ventilatory threshold (~65% VO_{2peak}), followed by a self-paced 2-km time trial (TT). RPE and respiratory measures were determined every 20 minutes. Strength was tested in a semi-reclined position [75° hip flexion, to facilitate femoral nerve stimulation] pre-exercise, after the 2-hr run and post-time trial as follows: voluntary isometric quad strength was measured on the Biodex with the knee flexed 60°, and with superimposed peripheral magnetic stimulation of the femoral nerve to determine central activation (CAR). **RESULTS:** Respiratory exchange ratio indicated that KETO (0.78) used less carbohydrate than NORM (0.86±0.01) during the 2-hr run. While we measured no fatigue of any kind in KETO, NORM declined in voluntary strength (-16±5%) and experienced loss of central drive to the muscle (CAR decreased from 0.85±0.04 to 0.76±0.05). KETO ran the TT at a mean pace of 16.4 km/hr compared to 14.8±0.7 km/hr in NORM.

CONCLUSIONS: Our KETO runner did not display strength loss and may have had better TT performance after exhausting exercise as compared to our NORM runners who exhibited central fatigue.

Impact Of Cardiorespiratory Fitness On Carbohydrate Utilization In Overweight And Obese Adults

Stephanie A. Xavier, Stephanie M. Wilson, Sarah Bronsky, Mary P. Miles, FACSM. *Montana State University, Bozeman, MT.*
 Email: xavier.stephanie.96@gmail.com
 (No relevant relationships reported)

Obese individuals have impaired metabolic flexibility compared to lean individuals. During exercise, this population relies more heavily on fat oxidation than carbohydrate oxidation for energy even at higher intensities. Although increased fat oxidation during exercise can be beneficial in lean individuals, increased fat oxidation during exercise in obese populations is a paradox. Examining the relationships of fat versus carbohydrate oxidation in obese subjects with different cardiorespiratory fitness levels, may help to explain these differences further. **PURPOSE:** To determine whether overweight and obese (OW/OB) individuals with higher versus lower cardiorespiratory fitness differ in their carbohydrate and fat utilization at 35, 50, 65, and 80% of VO_{2max} during a graded exercise test. **METHODS:** Adults (n=34), 28-55 years old with BMI 27-36 kg·m⁻² were measured for their age-predicted VO_{2max} using a modified Bruce protocol on a treadmill to 85% of age predicted heart rate maximum. Participants were first split into group based on sex and then divided for comparison into upper and lower halves based on age-predicted VO_{2max}. After they were split into within sex low and high groups, their carbohydrate and fat utilizations were compared at 35, 50, 65, and 80% of VO_{2max} and normalized to body mass. **RESULTS:** An intensity by fitness group interaction (p<0.05) was measured for both sexes. For women (n=10 per group), the low and high fitness groups were similar in carbohydrate oxidation at 35 and 50 of VO_{2max} and the high fitness women oxidized more (p=0.05) carbohydrate at 65% (mean +/- SD, 0.08 +/- 0.02 vs 0.06 +/- 0.03 kcal/kg/min) and 80% (0.20 +/- 0.09 vs 0.12 +/- 0.05 kcal/kg/min) VO_{2max}. For men (n=7 per group), both groups had similar carbohydrate oxidation at 35, 50, and 80% of VO_{2max} and the high fitness men oxidized more (p<0.05) carbohydrate (0.16 +/- 0.07 vs. 0.09 +/- 0.02 kcal/kg/min) at 65% VO_{2max}. Fat utilization did not differ between groups for either males or females. **CONCLUSIONS:** OW/OB adults with better cardiorespiratory fitness utilized more carbohydrates for energy during a graded exercise test at moderate or

moderate to high intensity and did not differ in fat utilization. Supported by Montana State University Research Initiative 51040-MUSRI2015-03 and USDA-NIFA 2017-67018-26367.

Effects Of Low-load, High-repetition Exercise And Sex On Metabolic Properties Of Skeletal Muscle

Kristian Pancevski. *University of Waterloo, Waterloo, ON, Canada.*
 Email: kpancevs@uwaterloo.ca
 (No relevant relationships reported)

INTRODUCTION. During exercise women are better able to initiate aerobic metabolism and are less reliant on anaerobic energy stores. Whether this metabolic difference persists during resistance exercise remains unknown. **PURPOSE.** To characterize fuel utilization patterns during a bout of low-load, high-repetition (LL-HR) resistance exercise and determine whether sex influences the fuel utilization pattern. **METHODS.** Twenty young, healthy participants (n=10 men and women) were recruited and matched for VO_{2peak} relative to fat-free mass and habitual resistance training. The LL-HR bout consisted of a circuit of chest press, leg extension, lat pulldown, hamstring curl, shoulder press, and leg press for 25-35 repetitions at 30% of 1RM with 30s rest between each exercise and 2 minutes rest between circuits. Muscle biopsies were taken prior to and following exercise and finger prick assessment of blood lactate was taken during the exercise bout. Western blot analysis was completed for assessment of the high-energy phosphate transfer (CK, phosphorylated CK, AMPD2) and glycolytic (GP, PFK, LDH H and M, PDHE1α, PDHK4, MCT 1 and 4, phosphorylated PDHE1α) pathways. Muscle content of creatine, ATP, lactate, P_i, pyruvate, and glycogen were also determined. Muscle fibre type was determined using myosin heavy chain immunofluorescence staining. **RESULTS.** Women had a higher proportion of type I muscle fibres than men (p=0.007). There were no sex differences in the protein content of any of the enzymes at rest. Men had higher content of muscle glycogen (p=0.001), lactate (p=0.02), ATP (p=0.01), and P_i (p=0.007) than women. Glycogen, ATP, and phosphorylation of CK and PDHE1α decreased in men and women with exercise (p<0.001). Phosphorylation of CK decreased to a greater extent in women (p=0.023) and women tended to use more glycogen (p=0.081) during exercise. Alternatively, creatine increased to a greater extent in men (p=0.026) and men tended to have a greater lactate concentration at the end of the exercise bout (p=0.097). **CONCLUSION.** Sex differences in fuel metabolism during LLHR resistance exercise exist. While women tend to utilize more glycogen during LLHR, men have a higher muscle lactate content, suggestive of a greater reliance on anaerobic metabolism.

POST BREAKFAST RESISTANCE EXERCISE AND REDOX STATUS RESPONSES IN PATIENTS WITH BETA THALASSEMIA MAJOR EXHIBITING INSULIN RESISTANCE

ATHANASIOS Z. JAMURTAS, FACSM, Kalliopi Georgakouli, Alexandra Stamperna, Chariklia K. Deli, Dimitris Draganidis, Athanasios Gatsas, Athanasios Poullos, Konstantinos Papanikolaou, Despoina Kaloudi, Vasilios Kourkoulitiotis, Ioannis Koutedakis, Ioannis G. Fatouros. *UNIVERSITY OF THESSALY, TRIKALA, Greece.*
 Email: ajamurt@pe.uth.gr
 (No relevant relationships reported)

Beta-thalassemia major is an inherited hemoglobin disorder that manifests within the first few months of life. Especially insulin resistance and diabetes mellitus are common consequences of iron overload in the pancreas. **PURPOSE:** To examine whether a session of resistance exercise can affect the redox status and improve postprandial hyperglycaemia in patients with beta-thalassemia major exhibiting insulin resistance. **METHODS:** Six patients (weight: 66.0 ± 16.6 kg, body fat: 37.6 ± 5.1 %, SBP: 104.5 ± 9.7 mmHg, DBP: 67.5 ± mmHg) underwent two trials (exercise and control) following breakfast meal ingestion, in a counterbalance order, separated by at least three days. In exercise trial, patients performed chest and leg press (3 sets of 10 maximal repetitions), while in control trial they rested. Blood samples were obtained in both trials: pre-meal, 45 min post-meal, immediately post, 1 hour post, 2 hours post and 24 hours post. Blood was analysed for TBARS, catalase, total antioxidant capacity (TAC) and glucose. **RESULTS:** No time or condition interaction was found for TBARS, catalase and TAC (Table 1). Blood glucose levels increased significantly following breakfast meal ingestion and were not differed between trials at the same time points.

Table 1: Redox and glucose responses following a post-breakfast resistance exercise session

CONCLUSIONS: A session of resistance training consisting of two major muscle exercises is not enough to influence changes in redox status or glucose metabolism in patients with beta-thalassemia major exhibiting insulin resistance.

Effect Of Wearing Lower-body Compression Garments During Prolonged Running On Substrate Oxidation And Running Kinematics

Sahiro Mizuno¹, Mari Arai², Eri Yamada², Fumihiko Todoko², Akitoshi Makino³, Masaki Ishikawa⁴, Kazushige Goto⁵. ¹Nagoya University, Nagoya, Japan. ²DESCENTE Ltd., Osaka, Japan. ³Osaka University of Health and Sports Science, Kusatsu, Japan. ⁴Osaka University of Health and Sports Science, Osaka, Japan. ⁵Ritsumeikan University, Kusatsu, Japan.
 Email: sahiro@nagoya-u.jp
 (No relevant relationships reported)

Lower body compression garments (CG) have been suggested previously to provide favorable effects during running. One of explanation for the benefits of wearing CG might be explained by augmented arterial blood flow by external pressure applied. Enhanced muscle perfusion can increase oxygen delivery to exercising muscle, thereby affecting oxygen uptake and substrate oxidation. Furthermore, wearing CG might assist the propulsive force by optimizing running kinematics as a result of the elastic nature of the garment, leading to less metabolic cost of running at a given speed. These insights may be advantageous in situation with prolonged running, which is required large metabolic demand under development of fatigue. However, little information is available for effect of wearing CG during prolonged running (> 1h) on energy metabolism and running kinematics. **PURPOSE:** To determine influence of wearing CG on energy metabolism and running kinematics during prolonged running. **METHODS:** Eight physical active male (24 ± 2 yrs, 168.4 ± 5.0 cm, 63.9 ± 5.0 kg, VO₂max; 54.8 ± 4.3 mL·kg⁻¹·min⁻¹) completed 2 exercise trial in the different days. The exercise consisted of 120 min of uphill running (7% gradient) at 60 % of VO₂max (6.8 ± 0.6 km·h⁻¹). The exercise trials included 1) wearing CG with exerting 15 mmHg [CG]; and 2) wearing garment with exerting below 5 mmHg [CON] to thigh and calf. Respiratory gas variables (carbohydrate oxidation) and running kinematics (step length and frequency, ground-contact time, flight time, joint angles) were assessed every 30 min of exercise. Blood samples were collected to determine blood glucose and lactate, and plasma IL-6 as indication of carbohydrate metabolism. *P* < 0.05 was considered to be statistically significant. **RESULTS:** Time course of changes in carbohydrate oxidation, running kinematics and blood glucose and lactate did not differ between the two trials (*P* > 0.05). Area under the curve (AUC) of plasma IL-6 concentration for 120 min of exercise tended to be lower in the CG trial (803 ± 452 pg·mL⁻¹) compared with in the CON trial (1,219 ± 842 pg·mL⁻¹, *P* = 0.07). A positive relationship was observed between the AUC of plasma IL-6 concentration and the total carbohydrate oxidation (*r* = 0.5, *P* = 0.049). **CONCLUSION:** Wearing CG did not alter energy metabolism and running kinematics during prolonged running.

Comparing The Effects Of Different Modes Of Exercise On Glucose Handling In Young Recreationally Active Men

Kayleigh Beaudry, Kirstian Pancevski, Claire Woodgate, Cory Tremblay, Michaela C. Devries. University of Waterloo, Waterloo, ON, Canada.
 Email: km2beaudry@uwaterloo.ca
 (No relevant relationships reported)

PURPOSE: The prevalence of type 2 diabetes (T2D) is increasing dramatically and is characterized by insulin resistance (IR). Exercise training is an effective modality to improve IR and acutely can increase post-exercise glucose handling for up to 72 hours. However, there is conflicting evidence as to which mode of exercise elicits the greatest positive effect on glucose handling. The purpose of this study was to compare the effectiveness of different modes of exercise on post-exercise glucose handling in young recreationally active men. **METHODS:** Twelve (age: 22±3 years) recreationally active men completed 4 separate oral glucose tolerance tests (OGTT) either at rest, or 1.5 hours after moderate-intensity continuous exercise (MICE; 30 min @ 65% VO₂peak), low-load high-repetition resistance exercise circuit (LLHR; 20-25 reps/set for 3 sets at 30% 1RM) and high-intensity interval training bout (HIIE; 10x1min at 90% HR_{max}). Heart rate and blood lactate were taken throughout the exercise bouts. Blood was analyzed for total plasma glucose concentration (mmol/L), c-peptide concentration (ng/mL) and blood insulin concentration (μIU/mL). **RESULTS:** Average blood glucose concentration during the OGTT was lower following LLHR (6.386 ± 0.261mmol/L, *p* = 0.03) as compared with MICE (6.839 ± 0.256 mmol/L, *p* = 0.03) with no differences between baseline (6.625 ± 0.333 mmol/L) and HIIE (6.737 ± 0.267 mmol/L). Glucose area under the curve (AUC) was lower following LLHR (781.76 ± 36.08) as compared

to MICE (842.81 ± 35.8; *p* = 0.033) with no difference compared to baseline glucose AUC (804.61 ± 46.7, *p* = 0.475). Blood c-peptide concentrations were not significantly different between baseline, MICE, HIIE or LLHR average concentrations. Similar to c-peptide there were no significant differences between blood insulin concentrations post exercise. **CONCLUSION:** In young, healthy men none of the exercise modes improved glucose handling as compared with baseline. However, LLHR resistance exercise did result in greater glucose clearance than MICE, suggesting that it may be a better modality to improve glucose control. Future work should examine the acute and chronic effects of LLHR resistance exercise on glucose handling in individuals with IR to determine the potential effectiveness of this exercise modality to improve insulin sensitivity.

The Effect Of Arm Versus Leg Dominant Physical Activity On Postprandial Blood Glucose Levels

Kabre C. Madrigal, Emma R. Powley, Matthew J. Laye. The College of Idaho, Caldwell, ID.
 (No relevant relationships reported)

PURPOSE: The aim of this investigation was to assess the effects of two different exercise trials that used different amounts of muscle mass on postprandial blood glucose levels. **METHODS:** Subjects (*n* = 8) participated in a series of three tests after ingesting a 75g 100% glucose solution: a control, a bout of arm-only exercise, and a bout of leg-only exercise following the standard OGTT protocol. Each exercise bout was thirty minutes in length, the intensity of which was matched at 0.5 watts/ kg of body weight between trials. **RESULTS:** The average postprandial blood glucose was significantly different between conditions (Two Way Repeated Measures ANOVA, *p* < 0.05). At 20 minutes blood glucose was significantly lower in legs conditions versus the arm condition (*p* = 0.003). There was no difference in mean HR or RPE between trials. **CONCLUSION:** The data suggests that when factors such as workload are matched, the amount of muscle mass recruited for light physical activity can impact postprandial blood glucose control. The results of this pilot study help to further define the role exercise could play in the prevention of increasingly prevalent metabolic disorders, helping people to live longer, healthier lives utilizing exercise as medicine.

Does Energy Expenditure Of Activity Interruptions In Prolonged Sitting Impact On Glycemic Responses?

Zhen-Bo Cao, Sheng-Xia Ma, Yan-Yu Lin, Xiao-Mei Liu, Zheng Zhu. Shanghai University of Sport, Shanghai, China.
 Email: caozb_edu@yahoo.co.jp
 (No relevant relationships reported)

PURPOSE: To explore the impact of energy expenditure (EE) on glycemic responses when prolonged sitting is interrupted by three regular activity bouts.

METHODS: Fourteen healthy, sedentary, inactive adults (8 women; age 23.7±2.9 y; BMI, 22.2±2.4 kg/m²; VO₂ max, 38.5±5.2 mL·kg⁻¹·min) completed four 26 h interventions in randomized order, including 22.5 h in an EE-testing calorimeter chamber. The four 9 h intervention periods were as follows: uninterrupted sitting (SIT); 30 min sitting/3 min brisk treadmill walk (60% VO₂max, WALK3); 45 min sitting/5 min brisk treadmill walk (WALK5); or 60 min sitting/8 min brisk treadmill walk (WALK8). Meals and meal times were standardized across the trials for all participants. After adjustment for age, sex, percent of body fat, relative VO₂max, treatment order, and corresponding baseline interstitial glucose concentrations, the relationship between EE and the incremental area under the curve (iAUC) for interstitial glucose was examined during the whole 26 h observation period and each segmentation period (intervention period, evening period, and sleep period). The interstitial glucose was obtained via continuous glucose monitoring. Random effects mixed model analyses were performed and data were represented as unstandardized coefficients with 95% confidence intervals.

RESULTS: Model parameter estimates revealed that EE was negatively associated with glucose iAUC during the intervention period ($\beta = -1.87 \text{ mmol} \cdot \text{h} \cdot \text{L}^{-1} \cdot \text{MJ}^{-1}$ [-3.68 - -0.05], *P* = 0.04) and positively associated with glucose iAUC during the 2 h post-dinner period immediately following the intervention period ($\beta = 0.64 \text{ mmol} \cdot \text{h} \cdot \text{L}^{-1} \cdot \text{MJ}^{-1}$ [0.27 - 1.00], *P* = 0.001). There was no significant association between EE and glucose iAUC during the entire 26 h observation or the other segmentation periods. The 2 h post-dinner iAUC was higher in men than in women (mean difference: 0.74 mmol·h·L⁻¹ [0.16 - 1.33], *P* = 0.01).

CONCLUSIONS: Higher EE after the interruption of sitting time was associated with lower interstitial glucose responses during the intervention period in healthy, sedentary adults, but the opposite was true in the 2 h postprandial period immediately following the intervention period.

Males And Females Exhibit Similar Muscle Glycogen Recovery Across Varied Diets

Brent C. Ruby, FACSM, Walter S. Hailes, Shannon K. Flynn, Alejandro M. Rosales. *University of Montana, Missoula, MT.*
 Email: brent.ruby@mso.umt.edu
 (No relevant relationships reported)

Research has demonstrated that post exercise glycogen recovery is altered by varied macronutrient intake and timing and in response to ambient or skeletal muscle temperatures. However, research has minimally considered the implications of glycogen recovery in females and has mostly focused on commercial sport nutrition products. **PURPOSE:** To determine the effects of varied mixed macronutrient feedings on glycogen recovery and subsequent exercise performance in both sexes. **METHODS:** Males (n=8) and females (n=8) participated in a counter-balanced crossover study. Subjects completed a 90-minute cycling glycogen depletion trial then rested for 4 hours. Two carbohydrate feedings (1.6 g kg⁻¹body weight each) of either sport supplements or potato-based products were delivered at 0 and 2 hours post exercise. Muscle biopsies and blood samples (glucose, insulin) were collected during the recovery. Following the 4-hour recovery period, subjects completed a 20km cycling time trial. Data were analyzed using 2 and 3 way ANOVA with repeated measures with statistical significance established at p<0.05). **RESULTS:** There was no difference between sexes or dietary sources for glycogen recovery rates (male: 7.9±2.7, female: 8.2±2.7, potato-based: 8.0±2.5, sport supplement: 8.1±3.1 mM · kg wet wt⁻¹ · hr⁻¹, p>0.05). Potato based feedings resulted in higher ratings for taste, satisfaction and acceptability (p<0.05). Time trial performance was not different between diets (38.3±4.4 and 37.8±3.9 minutes for potato and sport supplement, respectively, p>0.05). **CONCLUSION:** These results indicate that food items, such as potato-based products, can be as effective as commercially marketed sports supplements when developing glycogen recovery oriented menus and that carbohydrate dose recommendations (g kg⁻¹body weight) can be universally applied to both males and females. Interrupting Sitting With Short Walks Or Repeated Chair Stands Improves Glycemic Control In Healthy Adults

Stephanie Estafanos¹, Eric Williamson¹, Julia Malowany¹, Daniel R. Moore¹, Dinesh Kumbhare², Jenna B. Gillen¹. ¹University of Toronto, Toronto, ON, Canada. ²Toronto Rehabilitation Institute, Toronto, ON, Canada.
 Email: stephanie.estafanos@mail.utoronto.ca
 (No relevant relationships reported)

Uninterrupted sedentary time is an independent risk factor for the development of metabolic diseases. Interrupting prolonged sitting with brief, intermittent walks can improve postprandial glucose metabolism; however, the efficacy of other types of exercise that do not require equipment nor space beyond one's immediate sedentary area remain to be investigated. **PURPOSE:** To determine the impact of interrupting prolonged sitting with practical 'activity snacks' on postprandial glycemia and insulinemia in healthy adults. **METHODS:** Fourteen participants (7 males, 7 females; 23±5yr; 24±5kg/m²; 40±8ml/kg/min; 4587±1231steps/d) completed three 7.5hr trials in a randomized order consisting of uninterrupted sitting (SIT), sitting with intermittent (every 30 min) walking (WLK; 2min at 3.1mph) or sitting with intermittent squats (SQT; 15 'chair stands with calf raise'). Mixed-macronutrient liquid meals (~55:30:15% carbohydrate:fat:protein) provided 20% ('breakfast'; 406±87kcal) and 30% ('lunch'; 609±130kcal) of daily energy needs to mimic traditional Western meal patterns. Blood was obtained every 30min and analyzed for plasma glucose and insulin concentration. Positive incremental area under the curve (iAUC) for glucose, insulin and insulin:glucose ratio were calculated 1 and 3h postprandially using the trapezoidal rule. **RESULTS:** Postprandial glucose and insulin did not differ across conditions following breakfast. After lunch, peak insulin concentration was lower in SQT (51.6±26.7, p<0.001) and WLK (62.2±34.9, p<0.05) compared to SIT (78.9±43.0µIU/ml). The insulin:glucose iAUC 3h following lunch was also reduced by the activity snacks (SQT: 489±300; WLK: 541±401) compared to SIT (700±398, p<0.05). Insulin iAUC 1h following lunch was lower in SQT (1412±902, p<0.01) and WLK (1575±1145, p<0.05) relative to SIT (2231±1540µIU/ml x 1h, p<0.01), however 3h insulin iAUC was only reduced in SQT (SQT: 2992±1735 vs. SIT: 3954±2261µIU/ml x 3h; p<0.05). **CONCLUSION:** Interrupting prolonged sitting with short walks or repeated chair stands reduces postprandial insulinemia following lunch in healthy adults. Our results add to the evidence suggesting that short 'activity snacks' can help mitigate cardiometabolic risk factors associated with prolonged sitting. Supported by ACSM Research Endowment Grant.

Passive Stretch Improves Insulin-stimulated Glucose Transport Together With Downregulation Of TXNIP In Rat Soleus Muscle

Hiroki Honda¹, Song-Gyu Ra¹, Hiroki Iizawa¹, Shihoko Nakashima¹, Yuki Tomiga², Yasuki Higaki¹, Kentaro Kawanaka¹. ¹Fukuoka University, Fukuoka, Japan. ²Fukuoka University Institute for Physical Activity, Fukuoka, Japan.
 (No relevant relationships reported)

PURPOSE: Although passive stretch is known to stimulate muscle glucose transport independently of insulin action, it is unclear whether stretch increases susceptibility of glucose transport to insulin and improves insulin resistance in skeletal muscles. Therefore, we examined the effect of stretch on insulin-stimulated glucose transport in insulin resistant soleus muscles of immobilized rats. In addition, we examined the possibility that stretch decreases protein expression of TXNIP which is known to be a key negative regulator of insulin signaling. **METHODS:** Rats were divided into non-immobilized control and immobilized groups. Non-immobilized control rats were allowed to move freely in their cages. Immobilized rats were anesthetized and their both hindlimbs were immobilized for 6 h. Unilateral soleus muscles of immobilized rats were shortened by plantarflexing the ankle joint throughout 6 h immobilization. Contralateral muscles were stretched for 1 h by dorsiflexing the ankle joint following 5 h shortening by plantarflexing. We measured basal and insulin (50µU/ml) stimulated 2-deoxyglucose (2DG) uptake rate in isolated soleus muscles. Moreover, TXNIP protein expression was evaluated in these muscles. **RESULTS:** Although insulin (50µU/ml) increased glucose transport by 1.9-fold in soleus muscles of non-immobilized control rats (p<0.05), insulin did not significantly increase glucose transport in shortened muscles of immobilized rats. This result shows that insulin resistance is induced in these shortened muscles. On the other hand, 1 h passive stretch restored insulin resistance of glucose transport in muscles of immobilized rats (insulin-stimulated 2DG uptake in control, 3.12±0.29; shortened, 1.73±0.17; stretched, 3.04±0.31µmol/g muscle/20min). In addition, TXNIP protein was increased in shortened muscles of immobilized rats as compared with muscles of control rats (p<0.05). Moreover, elevated TXNIP expression in these muscles was returned to control level after 1 h passive stretch (TXNIP in control, 100±9; shortened, 166±8; stretched, 107±9 arbitrary units). **CONCLUSIONS:** Passive stretch improves insulin-stimulated glucose transport in insulin-resistant soleus muscles of immobilized rats. This may be due to stretch-induced downregulation in TXNIP protein expression.

Acute Hypoxia Suppresses Exogenous Glucose Rate Of Appearance And Metabolic Clearance Rate During Steady-state Aerobic Exercise

Lee M. Margolis¹, Marques A. Wilson¹, Claire C. Whitney¹, Christopher T. Carrigan¹, Nancy E. Murphy¹, Patrick N. Radcliffe¹, Jess A. Gwin¹, David D. Church², Robert R. Wolfe², Army A. Ferrando², Andrew J. Young, FACSM¹, Stefan M. Pasiakos, FACSM¹. ¹United States Army Research Institute of Environmental Medicine, Natick, MA. ²University of Arkansas for Medical Sciences, Little Rock, AR.
 Email: lee.m.margolis.civ@mail.mil
 (No relevant relationships reported)

BACKGROUND: Previously, we observed that exogenous carbohydrate oxidation is reduced when lowlanders perform steady-state aerobic exercise after 5 h exposure to high altitude (HA). However, the underlying glucose kinetics that may contribute to the reduction in exogenous carbohydrate oxidation during steady-state aerobic exercise performed at HA have not been explored. **PURPOSE:** Determine glucose turnover responses to exogenous carbohydrate ingestion during metabolically-matched, steady-state aerobic exercise at HA and sea level (SL). **METHODS:** Using a randomized, crossover design, lowlanders (n = 8 males, mean ± SD, age: 23 ± 2 yr, body mass: 87 ± 10 kg, and VO_{2peak}: SL 4.3 ± 0.2 L/min and HA 2.9 ± 0.2 L/min) consumed 145 g (1.8 g/min) of glucose while performing 80 min of metabolically-matched (SL: 1.66 ± 0.14 L/min $\dot{V}O_2$, 329 ± 28 kcal; HA: 1.59 ± 0.10 L/min $\dot{V}O_2$, 320 ± 19 kcal) treadmill exercise at SL (757 mmHg) and after 5 h of simulated HA (hypobaric hypoxia, 460 mmHg) exposure. Glucose rate of appearance (Ra), disappearance (Rd), and metabolic clearance rate (MCR), were determined during the last 40 min of exercise using primed, constant [6,6-²H₂] glucose infusions and ¹³C glucose-labeled drinks.

RESULTS: Exogenous glucose oxidation rate was lower ($P < 0.05$) at HA (0.35 ± 0.07 g/min) compared to SL (0.44 ± 0.05 g/min). Total glucose R_a was lower ($P < 0.05$) at HA (12.3 ± 1.5 mg/kg/min) compared to SL (13.8 ± 2.0 mg/kg/min). Exogenous glucose R_a was lower ($P < 0.05$) at HA (8.9 ± 1.3 mg/kg/min) compared to SL (10.9 ± 2.2 mg/kg/d), but there was no difference between endogenous glucose R_a at HA compared to SL. Glucose R_a and MCR were lower ($P < 0.05$) at HA (12.7 ± 1.7 mg/kg/min and 9.0 ± 1.8 mg/kg/min) compared to SL (14.3 ± 2.0 mg/kg/min and 12.1 ± 2.3 mg/kg/min).

CONCLUSION: Ingesting carbohydrate during steady-state aerobic exercise performed 5 h after arriving at HA is associated with lower exogenous glucose R_a , glucose R_a , and MCR compared to SL. These data suggest that altered glucose kinetics, indicative of either a reduction in exogenous glucose absorption or release from the gut, may contribute to lower exogenous carbohydrate oxidation during exercise upon initial exposure to HA.

Relationship Of Glucose Kinetics With Exercise Capacity, Body Composition, And Mitochondrial Function With Aging

Kevin J. Gries, Hawley E. Kunz, Corey R. Hart, Xiaoyan Zhang, Zachary C. Ryan, Ian R. Lanza. *Mayo Clinic, Rochester, MN.*
 Email: gries.kevin@mayo.edu
 (No relevant relationships reported)

Aging is commonly associated with decreases in aerobic capacity, skeletal muscle mass and function, as well as metabolic dysregulation including insulin resistance. **PURPOSE:** We sought to investigate relationships between these aforementioned hallmark traits of aging. **METHODS:** Young healthy adults (24-34 years; n=16; 7F/9M; BMI: 25 ± 3 kg/m²) and older adults (65-79 years; n=39; 20F/19M; BMI: 27 ± 4 kg/m²) were recruited as a part of this investigation. Subjects completed a graded maximal exercise test (VO_{2peak}) on a treadmill, a dual-energy X-ray absorptiometry scan, measurement of single-leg knee extension power, a mixed meal tolerance test upon which blood glucose was monitored throughout the next 5 hours, and a resting vastus lateralis biopsy to measure ATP production from permeabilized muscle fibers. **RESULTS:** Young had a 38% greater aerobic capacity and 45% greater knee extensor maximal power/lean mass. Fasting plasma glucose was lower ($P < 0.05$) in young (86 ± 7 mg/dL vs. 93 ± 8 mg/dL in young and old, respectively), as well as young had 31% lower plasma glucose area above baseline (AAB) in response to the mixed meal tolerance test compared to old ($P < 0.05$). No differences between young and old were observed in lean body mass, fasting plasma insulin, or maximal mitochondrial ATP production (state III). Interestingly, AAB was not significantly correlated with phenotypic characteristics (BMI or lean body mass), fasting plasma glucose or insulin, or maximal ATP production. However, AAB was significantly ($P < 0.05$) inversely correlated with VO_{2peak} relative to body mass ($r = -0.38$) and knee extensor power/lean mass ($r = -0.47$). **CONCLUSIONS:** These data suggest that glucose tolerance may be a function of skeletal muscle quality rather than total lean mass. However, the inverse relationship with AAB and measurements of whole body functional tests do not appear to be related mitochondrial energy production, suggesting the need for further mechanistic investigations. Hand Heating Lowers Fasting And Postprandial Blood Glucose

Jeff Moore, Jochen Kressler, Michael Buono, FACSM. *San Diego State University, San Diego, CA.* (Sponsor: Dr. Michael Buono, FACSM)
 Email: jmoore714@gmail.com
 Reported Relationships: J. Moore: Industry contracted research; AVACEN Medical.

Purpose: Examine the effect of hand heating with negative pressure on postprandial blood glucose (PBG) and fasting blood glucose (FBG). **Methods:** Design: Double-blind randomized controlled trial. Subjects: PPG experiment: 13 healthy subjects (2 males). FBG experiment: 17 healthy subjects (4 males). Interventions: Devices included one providing heat only, one heat and negative pressure, and one acting as a sham. For the PPG experiment the devices were used for one hour during an oral glucose tolerance test (75 grams dextrose). For the FBG experiment the devices were used for 30 minutes. Outcome Measures: Blood glucose measurements were used to determine peak PBG, area under the curve (AUC), incremental AUC (iAUC), and change in FBG. **Results:** PBG: Compared to the sham device the heat plus vacuum and heat only device lowered peak blood glucose by 16 ± 31 mg/dL, $p = 0.092$ and 18 ± 28 mg/dL, $p = 0.039$, respectively. AUC and iAUC: Compared to the sham device, the heat plus vacuum device and heat only device lowered the AUC by $3.7 \pm 14\%$, $p = 0.234$ and $7.7 \pm 11\%$, $p = 0.024$ respectively and iAUC by $17.2 \pm 53\%$, $p = 0.178$ and $20.5 \pm 34\%$, $p = 0.054$, respectively. FBG: The decrease in fasting blood glucose from 0 min to 30 min for the heat plus vacuum device and heat only device was 1.8 ± 4.8 mg/dL, $p = 0.07$ and 3.2 ± 5.3 mg/dL, $p = 0.01$, respectively. The sham device had no effect on

mean resting blood glucose as it was 92.6 mg/dL both pre and post-treatment ($p = 0.47$).

Conclusions: Local hand heating combined with negative pressure lowers fasting and postprandial blood glucose in healthy subjects.

EFFECTS OF INTERMITTENT LOW DOSE CARBON MONOXIDE INHALATION ON BLOOD GLUCOSE REGULATION IN OVERWEIGHT ADULTS: A RANDOMIZED CONTROLLED CROSSOVER TRIAL

Jesse A. Goodrich¹, Dillon J. Frisco¹, Shane P.P. Ryan², Alyssa A. Newman², S. Raj J. Trikha², Barry Braun, FACSM², Christopher Bell², William C. Byrnes, FACSM¹. ¹University of Colorado Boulder, Boulder, CO. ²Colorado State University, Fort Collins, CO. (Sponsor: William C. Byrnes, FACSM)
 Email: jesse.goodrich@colorado.edu
 (No relevant relationships reported)

PURPOSE: Low dose carbon monoxide (CO) inhalation upregulates several proteins important for glucose metabolism. However, it is not known whether CO's ability to upregulate proteins associated with glucose metabolism has consequences for whole body glucose metabolism which could have implications for both research and clinical fields. We hypothesized that low dose CO inhalation would improve the glucose and insulin responses to ingestion of an oral glucose bolus in overweight humans.

METHODS: Eleven young adults (5 male, 6 female; body mass index: $25-35$ kg/m²) were included in this randomized, placebo-controlled, single blinded crossover study. Following screening, subjects completed two 7-day protocols, separated by at least 4 weeks. Prior to (24-hours) and following 5 consecutive days of either once daily CO (males: 1.2 mL kg⁻¹ body mass; females: 1.0 mL kg⁻¹ body mass) or placebo (room air) inhalation, subjects underwent two-hour oral glucose tolerance tests (OGTT).

RESULTS: Although blood glucose was on average 5 mg/dl lower post-intervention compared to pre-intervention ($p < 0.001$), there were no significant main effects or interactions across experimental conditions for any OGTT parameters (presented as overall average and [95% CI]), including fasting glucose (84.0 [78.8-89.2] mg/dL; intervention x pre/post interaction $p = 0.53$), two hour post glucose (96.9 [87.2-107.0] mg/dL; $p = 0.71$), fasting insulin (4.82 [2.63-7.00] μ U/mL; $p = 0.33$), the homeostatic model of insulin resistance (1.04 [0.53-1.55]; $p = 0.45$) or the Matsuda Index (17.3 [6.24-28.3]; $p = 0.60$). **CONCLUSION:** 5 days of low dose CO administration did not influence the glucose and insulin responses to an OGTT in overweight adults. Since low dose CO inhalation is used in the assessment of hemoglobin mass and other physiological parameters, these findings allow researchers to utilize these procedures without concern of altering glucose metabolism.

There is strong evidence that short bouts of light-intensity post-meal exercise are effective at lowering post-prandial and 24-h glucose concentrations in older people with impaired glucose tolerance (IGT). It is unknown, however, whether these transient benefits result in more enduring improvements in glycemic control after training.

Purpose: To determine the effects of a home-based, 12-week post-meal walking program on improvements in glucose metabolism, as well as on changes in body composition in overweight (BMI = 30 ± 1.8 kg/m²) older adults (N=6; 72 ± 5.3 years) with IGT. **Methods:** Participants performed three 15-minute bouts of low-intensity (3 METs) walking beginning 30 minutes after each meal on five days per week for 12 weeks. Glucose and insulin responses to an oral glucose tolerance test were determined 48 h after the last exercise bout before and after training. Changes in body composition were determined using iDXA. **Results:** Overall adherence to the total training program (180 post-meal walking bouts) was 65%; however, participants reported completing an average of 82% of the post-dinner walks across the 12 weeks. Total areas under the curve for both glucose [29.5 ± 9.3 vs. 29.5 ± 8.9 (mg·dL⁻¹)·3h·10³] and insulin [9.2 ± 5.4 vs. 9.0 ± 4.4 (mg·dL⁻¹)·3h·10³] responses did not change between baseline and follow-up; however, HbA1c levels (6.45% vs. 5.86%) and the Whole Body Insulin Sensitivity Index (4.5 ± 3.6 vs. 5.8 ± 8.7) showed promising improvements following training. There were no changes to body weight, body fat, or lean mass; however, visceral fat volume decreased (688.7 ± 311.4 vs. 584.3 ± 306.0 cm³), and four of the six participants reduced their visceral fat mass by over 37g. **Conclusions:** Data from this pilot study suggest that the benefits of regular, low-intensity post-meal walking on glycemic control may not last beyond 24h in older adults with IGT. On the other hand, if

performed consistently over time, the transient benefits may result in more enduring improvements in HbA1c and particularly in visceral fat mass. Supported by NIH/NIA R56 AG050661

D-66 Free Communication/Poster - Energy Availability in Athletes

Thursday, May 28, 2020, 2:00 PM - 4:30 PM
Room: CC-Exhibit Hall

2238 Board #157 May 28 3:00 PM - 4:30 PM Examination Of Energy Needs Across 2-week High-Intense Functional Exercise Program In Recreational Athletes

Erin M. Moore¹, Toni M. Torres-McGehee², Justin M. Goins², Samantha R. Weber², Tim Bailey². ¹University of South Florida, Tampa, FL. ²University of South Carolina, Columbia, SC. (No relevant relationships reported)

Increases in physical activity without proper nutritional knowledge may expose recreational athletes to compromised energy needs and macronutrient profiles. **Purpose:** To examine the energy needs across a 2-week high intense functional exercise program in female and male recreational athletes. **Methods:** Thirty adults (age: 31.2 ± 8.1; females: 164.7 ± 7.1 cm, 69.9 ± 11.1 kg; body fat%: 29.2 ± 5.5%; males: n=12, 176.9 ± 6.2 cm, 89.5 ± 15.1 kg, body fat%: 22.3 ± 8.8%) participated in a larger cross-sectional study. Participants completed a demographic survey, a 7 day online dietary and exercise log across 2 weeks. Measurements included; height, weight, and DXA scan (body fat%) at the beginning of the study. Exercise energy expenditure (EEE) was calculated using Ainsworth/Heyward equations, energy availability (EA) was calculated by EA = ((EI - EEE)/FFMkg¹) and energy balance (EB) was calculated by EB = (EI - TDEE = 0). Macronutrients (CHO, PRO, and fats) were assessed using ACSM recommendations (recs.). Low EA (LEA) was defined at >30 kcal/FFMkg¹ and EB was defined as negative, balanced, or positive, and Macros were defined as low, within or above recs. **Results:** Results yielded LEA (week 1: 73.3%, n = 22, week 2: 80% n=24) and negative EB (week 1: 94.4%, n=17; 75.0%, n=9) across the two weeks. No significant differences were found between gender or training weeks for energy needs and Macros. Over the 2 weeks, participants demonstrated similar energy needs including: EI (week 1: 1752.3 ± 599.8 kcals, week 2: 1831.2 ± 634.4 kcals), EEE (week 1: 310.7 ± 63.7 kcals, week 2: 302.7 ± 62.1 kcals), EA: (week 1: 25 ± 10.1 kcal/FFMkg¹, week 2: 25.1 ± 9.8 kcal/FFMkg¹), TDEE (week 1: 2518.5 ± 266.1 kcals, week 2: 2543.1 ± 286.1 kcals), and EB (week 1: -766.2 ± 627.4 kcals, week 2: -712 ± 652.3 kcals). Macronutrients were also similar between weeks; with PRO intake within recommendations (week 1: 50%, n=15; week 2: 63%, n=17, n=6), CHO intake was extremely low (week 1: 96.7%, n=29; week 2: 93.3%, n=28), and fats were within recs. (week 1: 62.1%, n=18; week 2: 46.7%, n=9). **Conclusion:** Participants demonstrated consistent EI and EEE habits over the 2 weeks, however, the recreational athletes under consumed CHO and presented at risk for LEA and negative EB. This leads to compromised fueling for the EEE utilized during training. Funded by Avadim Technology

2239 Board #158 May 28 3:00 PM - 4:30 PM BODY COMPOSITION AND ENERGY BALANCE CHANGES IN FEMALE RUGBY ATHLETES ACROSS ONE COMPETITIVE SEASON

Johnathan L. Boring, Jessica M. Moon, Anthony M. Hagele, Travis Russo, Kayla M. Ratliff, Blumkaitis C. Julia, Richard A. Stecker, Petey W. Mumford, Richmond Scott, Kyle L. Sunderland, Chad M. Kerksick, FACSM. Lindenwood University, Saint Charles, MO. (No relevant relationships reported)

Achieving and maintaining energy balance (EB) is a key nutritional goal for competing athletes. Recently published formulas have allowed for the estimation of EB using measured body composition values, but limited data is available in team sport athletes, particularly female rugby athletes. **PURPOSE:** To determine the changes in EB in female rugby athletes across an entire competitive season by assessing body composition using DEXA at three time points: pre-season, post-season and off-season. **METHODS:** Female rugby athletes (Mean ± SD; 18.5 ± 0.8 yrs, 166.8 ± 4.0 cm, 73.7 ± 9.73 kg, 28.9 ± 4.3 % fat, n=8) had three DEXA scans completed during pre-season (day 0-30), post-season (day 100 - 120), and off-season (day 300-365) for determination of fat mass (FM), fat-free mass (FFM), and percent body fat. Changes in FFM and FM between scans were assessed for changes across the season in addition to estimating EB (EB (kcal•d⁻¹) = 1.0 + 9.5). Data was analyzed using factorial ANOVA

with repeated measures on time with paired samples t-test being used for post-hoc comparisons. A p-value of 0.05 was used for statistical determinations. **RESULTS:** No statistically significant changes were noted for fat mass (p = 0.83), fat-free mass (p = 0.76), or percent body fat (p = 0.53) were observed across the competitive season (see Table 1). In addition, EB did not exhibit any changes (p = 0.77) across the season (EB = -9.96 ± 69.3 kcals/day). **CONCLUSIONS:** Over the measured time period, female rugby athletes were found to largely be in energy balance as no statistically significant changes were observed for body composition or EB. These data help to inform coaches and athletes about the anticipated energy needs within the sport of rugby.

Table 1: Body composition and energy balance in female rugby athletes.

	PRE	POST	OFF
DXA Fat Mass (kg)	20.6 ± 5.7	20.7 ± 4.7	20.2 ± 6.2
DXA Fat-Free Mass (kg)	47.5 ± 4.5	47.2 ± 4.1	47.5 ± 4.7
DXA % Fat	28.9 ± 4.3	29.3 ± 3.8	28.5 ± 4.4
	PRE vs. POST	POST vs. OFF	PRE vs. OFF
EB (kcal/day)	2.42 ± 153.1	-17.9 ± 83.8	-9.96 ± 69.3
Days between DXA scans	136 ± 4	242 ± 84	378 ± 6

2240 Board #159 May 28 3:00 PM - 4:30 PM Comparison Of Energy Expenditure Observed Between Scheduled Activities In Female Collegiate Basketball And Lacrosse Athletes

Jessica M. Moon¹, Hannah Zabriskie², Bre R. Zanders¹, Patrick S. Harty³, Brad S. Currier⁴, Richard A. Stecker¹, Petey W. Mumford¹, Andrew Jagim⁵, Chad M. Kerksick, FACSM¹. ¹Lindenwood University, St. Charles, MO. ²Towson University, Towson, MD. ³Texas Tech University, Lubbock, TX. ⁴McMaster University, Hamilton, ON, Canada. ⁵Mayo Clinic Health System, Onalaska, WI. (Sponsor: Chad Kerksick, FACSM) (No relevant relationships reported)

Specific energy needs of team-sport female athletes have been understudied, particularly with regard to scheduled daily activities. **PURPOSE:** To examine the difference between energy expenditure changes in NCAA Div II female basketball (BBALL) and lacrosse (LAX) athletes depending on scheduled team activities. **METHODS:** All athletes (BBALL: n=10; 19.8±1.3 yrs, 173.9±13.6 cm, 74.6±9.1 kg, 27.1±3.2 % fat; LAX: n=20; 20.4±1.8 yrs, 168.4±6.6 cm, 68.8±8.9 kg, 27.9±3% fat) were outfitted with heart rate and activity monitors during four consecutive days on five different occasions (20 days total) across their competitive seasons to assess differences in activity energy expenditure (AEE), total daily energy expenditure (TDEE) and physical activity level (PAL). Data collected was categorized by type of scheduled daily activities: Practice, Game, Conditioning or Off. All dependent variables were analyzed using a mixed factorial ANOVA with paired sample T-Tests as post-hocs when necessary. **RESULTS:** All results are outlined below in Table 1. Independent of day type, TDEE, AEE, and PAL levels were greater (p<0.05) in LAX athletes. Changes between day types for each sport were significantly different (p<0.05) for TDEE, AEE, and PAL. **CONCLUSION:** Calculated levels for TDEE, AEE, and PAL in female collegiate BBALL and LAX athletes were determined to all be different, irrespective of the scheduled daily activity. LAX athletes, regardless of scheduled activities, had greater TDEE, AEE, and PAL compared to BBALL athletes. Caloric expenditure in female collegiate athletes varies significantly depending on scheduled team activities with energy needs progressively increasing between Off, Conditioning, Practice, and Games. Table 1: TDEE, AEE, and PAL, in practice, game, conditioning, off, and combined days, in female collegiate BBALL and LAX athletes.

Examination Of Low Energy Availability And Sleep In High-intensity Functional Exercise Program Athletes
 Samantha R. Weber¹, Toni M. Torres-McGehee¹, Justin Goins¹, Tim Bailey¹, Erin Moore², Jacob Kay¹. ¹University of South Carolina, Columbia, SC. ²University of South Florida, Tampa, FL.
 Email: weber.samanthar@gmail.com
 Reported Relationships: S.R. Weber: Industry contracted research; Study was funded by Avadim Technology.

Low energy availability (LEA) affects the body's physiological systems, which can negatively affect an athlete's performance and recovery. Athletes that participate in high-intensity functional exercise may not have adequate dietary intake to match energy needs or obtain optimal amount of sleep to recover fully.

PURPOSE: To examine the low energy availability (LEA) and sleep among male and female recreational athletes who engage in high-intensity functional exercise programs. **METHODS:** Thirty adults (age: 31.2 ± 8.1; males: n = 12, 176.9 ± 6.2 cm, 89.5 ± 15.1 kg; females: 164.7 ± 7.1 cm, 69.9 ± 11.1 kg) participated in a larger cross-sectional study. Participants completed a demographic survey, Pittsburgh Sleep Quality Scale, a 7-day online dietary and exercise log. Participants were measured for height, weight,

DXA scan (BMD), and RMR through indirect calorimetry (MedGem). ANOVAs examined differences between gender and energy needs, and Chi-squared analysis examined differences between gender and risk for LEA and Poor Sleep. **RESULTS:** Significant differences were found between gender and RMR (males: 2296.7±400.3 kg; females: 1761.7±341.6 kg; P=0.001), EI (males: 2027.5±694.5 kg; females: 1568.9±461.1 kg; P=0.038) and EEE (males: 357.8±60.3 kg; females: 279.3±44.4 kg; P≤0.01). No significant differences were found between gender and LEA (males: 24.8.7±12.2 kg; females: 25.0±8.9 kg). Overall risk for LEA was 66.7% (n = 20); however independently LEA was 50% (n=6) for males and 77.8% (n=14) for females. Overall, 63.3% (n=19) recreational athletes report poor sleep. No significant differences were found across gender and poor sleep, independently poor sleep for males was 50% (n=6) and females 72.2% (n=13). No significant differences were found between gender, poor sleep, and LEA. Of those at risk for LEA (n=20), 60% (n=12) also had reported poor sleep. **CONCLUSIONS:** Recreational athletes were at risk for both LEA and poor sleep, with a majority at risk for both. A combination of LEA and poor sleep can lead to poor performance and recovery from high-intensity exercises. Therefore, education to recreational athletes on the importance of dietary intake to match energy needs and encouragement for positive sleeping habits is imperative to optimize physiological recovery.

2242 Board #161 May 28 3:00 PM - 4:30 PM
Effects Of Relative Energy Deficiency On Metabolism And Biomarkers In Korean Male Athletes

Sihyung LEE¹, Kuniko Moto¹, Seungah Han², Taewoong Oh², Motoko Taguchi¹. ¹Waseda University, Tokorozawa-shi, Japan. ²Yongin University, Yongin-si, Korea, Republic of.
 Email: move3210@gmail.com
 (No relevant relationships reported)

2014 International Olympic Committee (IOC) consensus statement suggested the concept of 'Relative Energy Deficiency in Sport' (RED-S) presenting impaired physiological function caused by inadequate energy availability (EA) and it has been studying in many athletes. However, there are limited studies on Asian and male athletes.

PURPOSE: To investigate EA and its relationship with metabolic status, bone health, and endocrine changes which have been studied for RED-S consequences in Korean male collegiate soccer players during regular training season. **METHODS:** Twelve male athletes from the University soccer team in Korea participated in this study. The subjects completed subjective condition check form for one month and dietary record for energy intake (EI) with heart-rate monitoring for exercise energy expenditure (EEE) during one week. Body composition was measured using dual-energy x-ray absorptiometry (DXA) and physiological biomarkers were analyzed using blood and urine samples. Resting energy expenditure (REE) was measured using the Douglas bag method and predicted REE was calculated for REE_{ratio} (measured REE/predicted REE) to evaluate metabolic status. The subjects were categorized into two groups by EA level as having relative energy deficiency (RED; EA <30 kcal/kg FFM/d, n=5) or moderate energy status (MES; EA ≥30 kcal/kg FFM/d, n=7).

RESULT: Total mean EA was 31.9 ± 9.8 kcal/kg FFM/d and the RED group showed significantly lower EA (22.4 ± 2.9 vs 38.7 ± 6.6 kcal/kg FFM/d, p<0.05) with lower REE_{ratio} (0.96 ± 0.07 vs 1.09 ± 0.06, p<0.05) and REE/FFM (26.0 ± 1.7 vs 28.8 ± 1.4 kcal/kg/d, p<0.05) than the MES group. There was no difference in bone turnover markers. FSH was higher in the RED group (5.50 ± 1.01 vs 3.64 ± 1.41 mIU/mL, p<0.05) and IGF-1 was higher in the MES group (248.6 ± 51.2 vs 318.9 ± 43.4 ng/mL, p<0.05). The regression analysis showed that the athletes with lower EA were more likely to have the lower REE_{ratio} and IGF-1 levels.

CONCLUSION: Relative energy deficiency can result in lower metabolic status and IGF-1 levels, but there are no relations with bone health status and other endocrine status in Korean male collegiate soccer players.

2243 Board #162 May 28 3:00 PM - 4:30 PM
Energy Requirements And Intake Of Collegiate Athletes

Anita M. Gust, Ryan Ratcliff. University of Minnesota Crookston, Crookston, MN. (Sponsor: Charles Fountaine, FACSM)
 Email: agust@umn.edu
 (No relevant relationships reported)

Nutrition is an important aspect of sport performance, yet many athletes are unaware of how many calories they should, or do, consume on a daily basis. Limited literature exists comparing perceived energy requirements with actual energy requirements based on body composition. **PURPOSE:** To determine student athletes' awareness of energy requirements based on their body composition and physical activity level. **METHODS:** Athletes (N=41; 20 male and 21 female) were recruited from 7 of the 11 existing sports at a NCAA Division II institution. Knowledge of daily energy

requirements, estimated caloric intake, and a subjective indicator of physical activity level were assessed. Body composition, resting metabolic rate (RMR), and energy requirements were assessed via displacement plethysmography (ADP) (Bod Pod). Comparisons of in-season and out of season perceived caloric needs, estimated caloric intake, and actual energy requirements were made using paired sample T-tests. **RESULTS:** For males, significant difference were found between estimated caloric intake during in-season and energy requirements, if very active (2745 ± 973 vs. 4339 ± 564), $t(20) = -6.21$, $p < .001$, and if active (2745 ± 973 vs. 3672 ± 395), $t(20) = -3.70$, $p = .002$, and estimated intake out of season and energy requirements if very active (2627 ± 917 vs. 4339 ± 564), $t(20) = -7.21$, $p < .001$, and if active (2627 ± 917 vs. 3672 ± 394), $t(20) = -4.51$, $p < .001$. Significant differences were also found between in-season perceived and estimated intake (3085 ± 698 vs. 2745 ± 973), $t(20) = 2.89$, $p = .009$. For females, significant differences were also found between estimated intake during in-season and energy requirements if very active (2376 ± 653 vs. 3184 ± 378), $t(21) = -4.32$, $p < .001$, and estimated intake out of season and energy requirements if very active (1971 ± 880 vs. 3184 ± 378), $t(21) = -5.42$, $p < .001$, and if active (1971 ± 880 vs. 2676 ± 318) $t(21) = -3.30$, $p = .004$. **CONCLUSIONS:** Student athletes have limited knowledge of caloric needs as they relate to energy requirements as active or very active athletes. If estimated caloric intake represents actual daily intake, student athletes are not consuming adequate calories to meet energy needs. A follow-up study, using a three-day diet record, is being conducted and will be added to present study for further analysis.

2244 Board #163 May 28 3:00 PM - 4:30 PM
Risk Factors For Relative Energy Deficiency In Sport In Costa Rican Female Runners

Andrea Calvo-Castillo, Paula Delgado-Valverde, Catalina Capitán-Jiménez. *Hispanoamerican University, San José, Costa Rica.* (Sponsor: Anita M. Rivera-Brown, FACSM)
 Email: andre_93_c@hotmail.com
 (No relevant relationships reported)

Competing in weight sensitive sports increases the risk for low energy availability (EA) which is associated with health impairments. Most of the available evidence on syndromes that result from low energy availability is in female athletes. **PURPOSE:** To identify body composition, caloric intake, physical activity, and other risk factors for developing the syndrome of Relative Energy Deficiency in Sport (RED-S) in female runners. **METHODS:** 31 female recreational runners completed a sociodemographic and an adaptation to the RED-S CAT tool to evaluate 12 risks factors for RED-S, a 7-day weekly exercise record based on calories spent on training sessions using their heart rate monitor, a 3-day dietary record (two work days and one weekend day) completed with the app "My Fitness Pal" and a body composition evaluation by bioimpedance. Energy availability was calculated and classified as: No risk (≥ 45 kcal/kg LBM/day); Moderate risk ($30-45$ kcal/kg LBM/day); and At risk (≤ 30 kcal/kg LBM/day). **RESULTS:** Age of 33 ± 6.0 years with experience of 7 to 9 years. The average personal record in 10 kilometers was $40:24:48 \pm 2.0$ minutes. The average body mass was 53 ± 5.3 kg, $BMI = 20.9 \pm 1.6$ kg/m², a percentage of body fat = $26.4 \pm 3.7\%$ and lean body mass = 38.9 ± 3.1 kg. The average reported daily exercise caloric expenditure was 529.5 ± 176.4 kcal and daily caloric intake was 1679.5 ± 327.7 kcal. Results showed an EA of 1147.7 ± 343.3 kcal/day, or 29.6 ± 9.1 kcal/kg of LBM/day. Only 6% of the runners were classified as no risk, 42% as moderate risk and 52% as at risk. Other risk factors were history of interrupted menstrual cycles (42%), birth control pills (29%), non-nutritional technique to lose weight (22%), history of eating disorder (16%), stress fracture (10%), hormonal disorder (7%). There was a weak and non-significant correlation between EA and personal best ($r = -0.45$, $p = 0.811$). **CONCLUSION:** This group of Costa Rican runners demonstrate energy availability that is far below from the optimal and various risk factors to develop the syndrome of Relative Energy Deficiency in Sport.

2245 Board #164 May 28 3:00 PM - 4:30 PM
A Nutritional Intervention In Exercising Women With Oligo/Amenorrhea Improved Energy Availability

Kristen J. Koltun, Rebecca Mallinson, Nancy I. Williams, FACSM, Mary Jane De Souza, FACSM. *Penn State University, University Park, PA.* (Sponsor: Mary Jane De Souza, FACSM)
 Email: kristen.koltun@gmail.com
 (No relevant relationships reported)

Reduced energy availability (EA) suppresses reproduction and induces oligo/amenorrhea (O/A) in exercising women. Treatment goals are to increase energy intake (EI) to improve EA and restore menstrual function. **Purpose** Determine if a nutritional intervention that increased EI in exercising women with O/A improved EA and energetic status. **Methods** A 12 month randomized controlled trial designed to increase energy intake 20-30% above baseline energy needs in exercising women with O/A randomized participants into O/A+CAL (n=13) and Control (n=10) groups. EI and exercise energy expenditure (EEE) were assessed throughout the intervention. EA was calculated as EI-EEE/fat free mass (FFM). Fasting blood samples were collected to

assess TT₃ and leptin. Independent t-tests/Mann-Whitney U tests compared differences between groups and correlations were run between changes in energy and hormones. Data are mean \pm SE. **Results** Subjects were 22 ± 1 yr, BMI 20.0 ± 0.4 kg/m². Menstrual recovery was observed and previously reported. There were no pre intervention differences in EI (1837 ± 95 kcal/d), EEE (390 ± 40 kcal/d), FFM (41.5 ± 0.8 kg) or EA (37.2 ± 2.7 kcal/kg FFM/d) between groups. During the intervention there were greater absolute and percent increases in EI in O/A+CAL vs Control (448 ± 170 vs -117 ± 147 kcal/d, $p = 0.02$; 23.6 ± 8.6 vs $-4.6 \pm 8.4\%$, $p = 0.03$). There were no differences between groups in absolute or percent change for EEE (133 ± 46 kcal/d, $p = 0.07$; $38.8 \pm 11.3\%$, $p = 0.10$) or FFM (0.6 ± 0.3 kg, $p = 0.60$; $1.6 \pm 0.7\%$, $p = 0.51$). Absolute increase in EA was greater in O/A+CAL vs Control (10.8 ± 5.5 vs -6.0 ± 3.9 kcal/kg FFM/d, $p = 0.03$), but no difference in percent change (29.2 ± 13.4 vs $-6.7 \pm 12.5\%$; $p = 0.07$). Absolute and percent increase in fat mass (2.3 ± 0.3 vs 0.7 ± 0.5 , $p < 0.01$; 20.6 ± 3.1 vs $5.4 \pm 3.2\%$, $p < 0.01$) and body mass (3.2 ± 0.3 vs 0.8 ± 0.8 , $p < 0.01$; 6.1 ± 0.7 vs $1.5 \pm 1.3\%$, $p < 0.01$) were greater in O/A+CAL vs Control. O/A+CAL had larger absolute and percent increases in TT₃ (10.3 ± 5.0 vs -6.7 ± 5.3 ng/dL, $p = 0.03$; 17.2 ± 7.4 vs $-8.3 \pm 5.5\%$, $p = 0.02$) and percent increase in leptin (85.1 ± 24.0 vs $-13.3 \pm 18.0\%$) vs Control. Changes in EI and EA were not associated with changes in hormonal markers. **Conclusion** An intervention designed to improve EI can be considered an effective nutritional intervention for managing oligo/amenorrhea in exercising women.

2246 Board #165 May 28 3:00 PM - 4:30 PM
Body Composition And Energy Balance Changes In Collegiate Female Swimmers

Kayla M. Ratliff, Julia C. Blumkaitis, Johnathan L. Boring, Anthony M. Hagele, Jessica M. Moon, Richard A. Stecker, Petey Mumford, Kyle S. Sunderland, Scott Richmond, Chad M. Kerkick, FACSM. *Lindenwood University, St. Charles, MO.* (Sponsor: Dr. Chad Kerkick, FACSM)
 (No relevant relationships reported)

Maintaining energy balance (EB) throughout training and competition should be a primary goal for competing athletes. Female athletes, in particular, may be prone to low energy availability which can reduce performance and negatively impact training adaptations observed. Regular determination of EB is challenging due to the need for accurate dietary intake and energy expenditure. However, recently published formulas have allowed for the estimation of energy balance using body composition derived computation, but comparisons across competitive seasons in various sports are limited. **PURPOSE:** To examine the changes in body composition and EB in collegiate female swimmers across an entire competitive season. **METHODS:** Thirteen female NCAA Division II swimmers (mean \pm SD: 19.5 ± 1.2 years; 68.9 ± 8.6 kg; 169.9 ± 8.8 cm) were evaluated annually at the beginning of two competitive seasons. Fat mass (FM), fat-free mass (FFM), and body fat percentage (BF%) were evaluated with dual-energy x-ray absorptiometry (DEXA) and changes in energy balance (EB) were calculated as $1.0(\Delta FFM/\Delta \text{time}) + 9.5(\Delta FM/\Delta \text{time})$. Data was analyzed using paired samples t-tests. A p-value of 0.05 was used for statistical determinations. **RESULTS:** Approximately 406 days separated each DEXA scan. Although body mass was not significantly affected (Year 1: 68.9 ± 8.9 kg vs. Year 2: 69.4 ± 8.2 kg, $p > 0.05$), a negative EB was observed (-67.0 ± 51.3 kcal·day⁻¹) across the season. Significant changes ($p < 0.001$) in FM (Year 1: 18.6 ± 5.0 kg vs. Year 2: 15.4 ± 5.1 kg), BF% (Year 1: $28.0 \pm 4.9\%$; Year 2: $23.4 \pm 5.7\%$), and FFM were observed across time (Year 1: 47.0 ± 5.3 kg vs. Year 2: 50.2 ± 4.8 kg). **CONCLUSION:** Assessments of changes in body composition and energy balance are important considerations for athletes and coaches regarding the health and performance of athletes. From Year 1 to Year 2, female swimmers were largely successful at maintaining their energy balance while significantly improving FM, FFM, and %BF. Body composition derived assessment of energy balance can be used to provide general indications of energy balance status in athletes across large periods of time.

2247 Board #166 May 28 3:00 PM - 4:30 PM
Examination Of Low Energy Availability (LEA) And Macronutrient Intake Among Beach Volleyball Players

Stephanie A. McKeen¹, Toni M. Torres-McGehee¹, Dawn M. Emerson², Kelly Pritchett³, Allison B. Smith¹, Meaghan Minori¹. ¹University of South Carolina, Columbia, SC. ²University of Kansas, Lawrence, KS. ³Central Washington University, Ellensburg, WA.
 (No relevant relationships reported)

Low energy availability (LEA) may be prevalent in female collegiate beach volleyball players, which can be a catalyst for negative health consequences. Athletes can present in a state of LEA as a result of inadequate intake of the recommended macronutrients; those being proteins (PRO), carbohydrates (CHO), and fats.

Purpose: Examine the prevalence of LEA and macronutrient intakes (PRO, CHO, and fats) among NCAA Division I female collegiate beach volleyball players.

Methods: Data from a larger cross-sectional study was used to examine recreational athletes (n=18; age: 19.8±1.4 years; height: 174.4±5.5 cm; weight: 63.2±5.1 kg). Athletes were moderately trained (exercised a minimum of 3-4 days/week). Data collection consisted of anthropometric data, surveys (e.g., demographics, age, gender, etc.), resting metabolic rate (RMR), a 7-day online dietary log to measure energy intake (EI), and exercise logs to measure exercise energy expenditure (EEE). Basic descriptive statistics, Chi-squares, and cross-tabulations were used to examine the proportion of participants classified as "at risk" for LEA (<30 kcal/kg/FFM) and the proportion that met the macronutrient recommendations.

Results: Overall, beach volleyball players demonstrated the following, with 94.4% (n=17) being identified as at risk for LEA: Average energy availability (EA): 12.4±9.6 kcal/kg FFM and average EEE: 1108.7±157.6 kcals. RMR recommendations for average minimal caloric intake for the sample was 1477.7±272.3 kcals; however, 55.6% (n=10) did not meet the recommendations. Recommended CHO and PRO macronutrient intake were not met by 100% and 61.1% of the sample, respectively. Overconsumption of fat compared to the recommendation was found in 33.3%.

Conclusions: Beach volleyball athletes in this sample were severely and alarmingly at risk for LEA. Most of the athletes demonstrated low CHO and PRO intake while overconsuming fat compared to the recommendations. These athletes would benefit from nutrition education focused on properly fueling and macronutrient intake, which are both essential for elite performance in the athletic arena.

Body-composition Derived Energy Balance Changes Across An Entire Female Division II Basketball Season

Anthony M. Hagele, Travis Russo, Johnathan L. Boring, Jessica M. Moon, Julia C. Blumkaitis, Richard A. Stecker, Kyle L. Sunderland, Petey W. Mumford, Scott Richmond, Chad M. Kerksick, FACSM, *Lindenwood University, St. Charles, MO.* (Sponsor: Chad Kerksick, FACSM)
 Email: amh524@lindenwood.edu
 (No relevant relationships reported)

Limited data is available using body composition-derived metrics to establish energy balance (EB) in team-sport athletes, especially female athletes. Tracking EB is important for coaches and athletes to understand how well the energetic demands of training and competing are being met by the diet. **PURPOSE:** The purpose of this study was to determine and track changes in energy balance across an entire competitive season in female Division II basketball athletes. **METHODS:** Eight female NCAA Division II basketball athletes (mean ± SD: 19.3 ± 0.9 yrs.; 72.8 ± 7.7 kg; 176.0 ± 7.4 cm; 24.8 ± 3.2 % body fat) underwent three dual-energy x-ray absorptiometry (DXA) scans over approximately 12 months, separating the season into two phases (in-season, [IS, Week 1-24], offseason [OS, Week 24-49]) and combined to form a full season (FS, Week 1-49). Body composition derived energy balance (kcal·d⁻¹) was estimated from changes in fat free mass (FFM) and fat mass (FM) between scans using the formula: EB (kcal·d⁻¹) = 1.0 + 9.5 · Data was analyzed using factorial ANOVA with repeated measures on time. A p-value of 0.05 was used for statistical determinations. **RESULTS:** Across the FS, a positive EB of 87.4 ± 36.4 kcal·d⁻¹ was observed (P > 0.05), which tended to decrease across the entire season (p = 0.06). A net decrease in FFM (-0.52 ± 0.10 kg) and increase in FM (3.2 ± 0.5 kg) was observed. During IS, EB was greater (137.6 ± 29.1 kcal·d⁻¹) due to significant changes (p<0.05) in FM (2.7 ± 0.5) and FFM (-2.6 ± 0.4). During the OS, EB was 39.6 ± 81.0 kcal·d⁻¹, with an increase in mean FFM (2.0 ± 0.38 kg, P < 0.05) and FM (0.5 ± 0.5 kg, P > 0.05). **CONCLUSIONS:** Results from this study suggest that female collegiate basketball athletes were largely able to maintain energy balance across an entire season. A mean positive EB observed over the season which overlapped with negligible changes in FM and FFM suggest a suitable matching of energy intake and energy demands across the FS. This information is useful for athletic performance staff, who should be aware of EB when providing athletes with proper nutrition and fueling strategies, particularly during the IS period to maintain appropriate energy balance when travel, classes, and food access may complicate energy intake and also during OS when training goals should be achieved.

2249 Board #168 May 28 3:00 PM - 4:30 PM
Changes In Body Composition And Energy Balance In Collegiate Female Gymnasts Over Multiple Competitive Seasons

Travis Joseph William Russo, Anthony M. Hagele, Johnathan L. Boring, Petey Mumford, Julia Blumkaitis, Kayla M. Ratliff, Jessica M. Moon, Richard A. Stecker, Scott Richmond, Kyle Sunderland, Chad M. Kerksick, FACSM, *Lindenwood University, St. Charles, MO.* (Sponsor: Chad Kerksick, FACSM)
 Email: tr973@lindenwood.edu
 (No relevant relationships reported)

The maintenance of energy status is an important dietary goal for competing athletes to properly fuel efforts, promote recovery, and prevent onset of illness or decrements in performance. Recent work in competing male athletes has reported on energy balance using body-composition derived parameters, but limited data is available highlighting changes in female athletes, and in particular female athletes who participate in physique sports. **PURPOSE:** To assess the changes in body composition and energy balance in female collegiate gymnasts over multiple competitive seasons. **METHODS:** 19 NCAA Division II collegiate female gymnasts (Mean ± SD; 18.4 ± 0.68 yr, 59.4 ± 4.5 kg, 160.9 ± 5.4 cm, 22.6 ± 2.2 % fat, 18.0±1.2 kg/m² fat free mass index) underwent dual-energy x-ray absorptiometry (DEXA) scans at the start of each season. Data was collected on all 19 subjects over three years with nine subjects being extended to a fourth year. Energy balance (EB) was calculated using a previously validated equation (EB= 1.0(Δ FFM/Δ Time) + 9.5(Δ FM/Δ Time) using fat free mass (FFM), time (days between scans) and fat mass (FM). A factorial ANOVA with repeated measures on time was conducted for changes in FFMI and Δ EB. Individual paired samples T-Tests were conducted when significance was found. **RESULTS:** Significant differences (p<0.05) between EB at year 1 (26.1 ± 46.7 kcals/day) and year 2 (-20.3 ± 57.9 kcals/day). Differences were also found (p<0.05) between years 2 (-20.3 ± 57.9 kcals/day) and year 3 (48.9±59.7) among the 9 subjects whose data extended to a fourth scan. No statistical significance was found (p > 0.05) between FFMI levels between year 1 (18.0 ± 1.2 kg/m²), year 2 (18.1 ± 0.8 kg/m²), and year 3 (18.3 ± 1.3 kg/m²). **CONCLUSION:** Changes in energy balance were largely stable in competitive female gymnasts across three years periods of time. Additionally and in concert, FFMI levels were also found to be stable across the measurement period. While statistically significant differences were present, the practical significance of these differences is not deemed to be relevant. Additional research is needed in all female athlete population to help identify and understand what dietary changes may be needed to best promote health, performance, and recovery.

2250 Board #169 May 28 3:00 PM - 4:30 PM
Examination Of Energy Availability And Hydration Status Among University Marching Band Artists

Toni Marie Torres-McGehee¹, Dawn M. Emerson², Samantha R. Weber¹, Nancy Uriegas¹, Allison B. Smith¹, Rebecca Hirschhorn¹, Susan Yeargin¹, Cormac Cannon¹. ¹*University of South Carolina, Columbia, SC.* ²*University of Kansas, Lawrence, KS.*
 Email: torresmc@mailbox.sc.edu
 (No relevant relationships reported)

Marching band (MB) members rehearse for pre-game and half-time performances outdoors for several hours a day starting at the end of July or beginning of August. There is lack of research on energy needs (e.g., energy availability) and proper hydration in MB during these hot months. **PURPOSE:** To examine energy availability and hydration status among MB members. A secondary purpose was to examine differences between sex. **METHODS:** We utilized data from a larger cross-sectional study. MB artists (n=37, Males: n=12, age: 19.8±1.4 years, height: 177.1±7.8 cm, weight: 74.6±23.8 kg; Females: n=25, age: 20.0±1.1 years, weight: 68.4±16.4 kg; height: 163.3±4.6 cm) from an NCAA Division I institution completed a survey (eg, basic demographics, band background, etc.) and were measured for height, weight, body composition, and resting metabolic rate (RMR). For 7-days, participants completed an online dietary log to measure energy intake (EI), wore a Polar m200 watch to estimate exercise energy expenditure (EEE) during rehearsals and gameday performances, and provided a morning urine sample to measure urine specific gravity (Usg). Low energy availability (LEA) was defined as <30 kcal/kg FFM/day and hypohydration was Usg >1.025. Basic descriptive statistics examined all energy needs and Usg. Chi square were used to identify proportions of members "at risk" for LEA and hypohydration and compared the differences across sex. **RESULTS:** Significant differences were found for EI for males and females respectively (2090.2±676.7 kcal, 1531.0± 460.8 kcals, P=.002). No significant differences were found for EEE and EA for males and females (335.5±66.0 kcal, 333.8± 66.9 kcals and 23.6±11.0 kcal/kg FFM, 22.9± 10.1 kcal/kg FFM). Overall, 73.7% (n=28) were at risk for LEA. No significant differences were found for Usg and sex (Males: 1.022±.006, Females: 1.022±.005), however 36.8% (n=14) reported chronically hypohydrated (≥ 4/7 days >1.025). Of those with LEA (n=28), 31.6% (n=12) also reported to be chronically

hypohydrated. **CONCLUSION:** The majority of MB members had LEA and over a third were also chronically hypohydrated. Due to performances in hot and humid environments, as well as the physical demands associated with MB, healthcare professionals should provide resources and education on hydration and proper fueling for MB artists.

Evaluation Of The Assessment Of Energy Availability In The Field

Michelle T. Barrack. *California State University Long Beach, Long Beach, CA.*
Email: michellebarrack@gmail.com
(No relevant relationships reported)

PURPOSE: The current study aimed to evaluate Sports Dietitian's methods of assessing energy availability (EA) in the field.

METHODS: Eligible participants were provided with a detailed web-based survey evaluating relevant elements of the assessment of EA among other related indicators. **RESULTS:** A total of 112 Sports Dietitians (n= 105, 93.8% female) participated. Over half (n= 62, 55.4%) were Board Certified Specialists in Sports Dietetics (CSSD), with a majority practicing in a collegiate (n= 41, 36.6%), private practice (n= 31, 27.7%), or professional team (n= 31, 27.7%) setting. While 67% (n= 75) reported measuring energy balance while assessing athletes, only 41% noted evaluating energy availability. A higher proportion of Sports RDs practicing ≥ 7 years compared to < 7 years acknowledged assessing EA (59.5% vs. 27.6%, $p = 0.001$, $X^2 = 10.3$). Sports RDs used a variety of methods to evaluate energy intake, including evaluation of "typical intake" during one-on-one session (n= 54, 48.2%), food log(s) (n= 30, 26.8%), 24-hour recall (n= 15, 13.4%), a combination (n= 5, 4.5%), or "other" method (n= 8, 7.1%), exercise energy expenditure, including activity factor estimates (n= 58, 51.8%), exercise logs (n= 32, 28.6%), a combination (n= 11, 9.8%), heart rate monitor (n= 6, 5.4%), or "other" methods, and body composition, including bioelectrical impedance analysis (n= 15, 13.4%), air displacement plethysmography (n= 15, 13.4%), dual energy x-ray absorptiometry (n= 14, 12.5%), and skinfold thickness (n= 11, 9.8%)

CONCLUSIONS: A majority of Sports Dietitians did not report regularly evaluating energy availability in their assessments of athletes. The variables used to calculate EA (i.e. EL, EEE, fat free mass) were evaluated using a variety of methods ranging in their level of potential error. Due to the potential difficulty and limitations of evaluating EA, development of a protocol for assessing EA may aid in increasing frequency and accuracy EA assessments in the field.

Number Of Inactive Adults With Arthritis Who Can Improve Their Anxiety And Depression By Exercising

George A. Kelley, FACSM¹, Kristi Sharpe Kelley¹, Leigh F. Callahan². ¹West Virginia University, Morgantown, WV. ²University of North Carolina @ Chapel Hill, Chapel Hill, NC.
Email: gkelley@hsc.wvu.edu
(No relevant relationships reported)

State-level estimates of the number of physically inactive adults with arthritis and other rheumatic and musculoskeletal diseases (RMDs) who can improve their anxiety and depression is currently unknown but important given that national data may not be appropriate for the conditions observed in each state. **PURPOSE:** Provide state-level estimates of the number of physically inactive adults in the United States with RMDs who could improve their anxiety and depression by exercising. **METHODS:** Utilizing (1) number-needed-to treat (NNT) data from two prior meta-analyses of randomized controlled trials addressing the effects of exercise on anxiety and depression in adults with RMDs, (2) recent age-adjusted, state-level prevalence estimates on arthritis and physical inactivity in adults with arthritis and other RMDs, and (3) state-level 2000 US Census population data, the number of physically inactive adults with RMDs who could improve their anxiety and depression by exercising was estimated. **RESULTS:** Across all states, the number of adults with RMDs who could improve their anxiety and depression by starting an exercise program was estimated at 2,622,907 for anxiety

and 2,245,962 for depression. For anxiety, numbers ranged from 3,583 (95% CI = 2,592 - 4,863) in the District of Columbia to 201,173 (95% CI = 156,923- 254,135) in Texas. For depression, numbers ranged from 3,068 (95% CI = 2,219 - 4,164) in the District of Columbia to 172,262 (95% CI = 134,37 - 217,613) in Texas. **CONCLUSIONS:** These findings provide important state-level information regarding the number of physically inactive adults in the United States with RMDs who could improve their anxiety and depression by exercising. This information should be useful to both interventionists and decision-makers.

2254 Board #173 May 28 2:00 PM - 3:30 PM
12 Weeks Of Maximal Strength Training Restores Muscle Force-generating Capacity In Patients With Schizophrenia

Mona Nygård¹, Mathias F. Brobakken¹, Joshua L. Taylor¹, Solveig K. Reitan¹, Ismail C. Güzey¹, Gunnar Morken¹, Einar Vedul-Kjelsås¹, Eivind Wang¹, Jørn Heggelund². ¹The Norwegian University of Science and Technology, Trondheim, Norway. ²St. Olavs University Hospital, Trondheim, Norway.
Email: mona.nygard@ntnu.no
(No relevant relationships reported)

Patients with schizophrenia spectrum disorders (ICD-10) suffer from impaired muscle force-generating capacity (MFGC) and functional performance of the lower extremities. **PURPOSE.** To investigate if 12 weeks of maximal strength training (MST) would restore MFGC and functional performance. **METHODS.** Forty-eight outpatients (28 men, 35±10 yrs; 20 women, 35±12 yrs) were randomized to a training group (TG) or control group (CG). Forty-eight age and gender matched healthy controls (28 men/20 women, 35±11 yrs) were tested to establish reference values. TG performed leg press MST (4x4 repetitions) 2d/week for 12 weeks at ~90% one repetition maximum (1RM). CG received two sessions of MST and encouragement to follow traditional physical activity guidelines. **RESULTS.** 17/24 patients in the TG (12 men/5 women, 34±11 years) completed 79% of training sessions and 19/22 patients in the CG (9 men/10 women, 37±12 years) completed the study. TG improved 1RM (28%, 12.6±4.1 to 16.2±5.0 Kg·m^{-0.67}, $p < 0.01$) and rapid force development (20%, 18.6±8.6 to 22.4±10.8 N·m·s⁻¹·m^{-0.67}, $p < 0.01$), reaching 106% and 85% of healthy reference values, respectively. TG improvements differed from CG ($p < 0.01$) where no changes occurred (1RM; 11.4±3.0 to 12.0±2.7 Kg·m^{-0.67}, rapid force development 16.4±6.9 to 17.3±6.5 N·m·s⁻¹·m^{-0.67}). Both TG and CG improved 30-second sit-to-stand test (30sSTS) performance (15±3 to 17±4 stands and 13±3 to 14±3 stands, respectively, $p < 0.05$). Changes were not apparent as between group difference nor close the gap to reference levels (27±5 stands). **CONCLUSION.** MST restored the patients' lower extremity MFGC and improved 30sSTS performance. Supported by grants from the Norwegian ExtraFoundation for Health and Rehabilitation, The Liaison Committee between the Central Norway Regional Health Authority and the Norwegian University of Science and Technology, and The Norwegian Directorate of Health.

Exercise Is Medicine For Mental Illness: Insights From Mental Health Professionals

Gina M. Besenyi¹, Raeann C. Bramwell¹, Katie M. Heinrich¹, Joseph P. McEvoy², Catherine L. Davis². ¹Kansas State University, Manhattan, KS. ²Augusta University, Augusta, GA.
Email: gbesenyi@ksu.edu
(No relevant relationships reported)

PURPOSE: Serious mental illness (SMI) is a major public health concern linked with adverse outcomes (premature mortality, cardiovascular disease, obesity).^{1,2} Physical activity (PA) has effectively reduced health risks,^{3,6} yet challenges exist for effective PA treatment delivery and sustainability in SMI populations.^{7,8} Certified peer specialists (CPSs), trained persons with lived recovery experience working in mental health settings, offer a potentially sustainable and reimbursable delivery mechanism for Exercise Is Medicine (EIM) PA interventions.⁹ This study examined CPSs' insights on the feasibility and acceptability of an EIM intervention in adults with SMI delivered in peer group settings. **METHODS:** Qualitative data were collected Spring/Summer 2018 through 4 focus groups of 3-6 people per group. CPSs were recruited through two behavioral health facilities in Kansas (n=11) and Georgia (n= 8). Semi-structured focus group guides elicited information regarding knowledge of PA, current PA with SMI peers, role of the CPS to promote PA, and feasibility of administering a PA intervention. Audio files were transcribed verbatim and analyzed with NVivo11 using qualitative content analysis with an inductive approach.^{10,11} **RESULTS:** Focus groups averaged 49±8 minutes. Data were coded into four themes: knowledge of PA, current PA with SMI peers, role of the CPS to promote PA, and PA intervention administration. CPSs stated their knowledge of PA is general and mostly comes from personal experience or internet searches. CPSs agreed their role covers Whole Health Action Management principles including promoting and participating in PA with SMI peers. CPSs were eager to participate in a PA intervention and willing to complete PA

training or certification. PA intervention administration included input on PA duration, frequency location, time of day, resources needed, motivators (e.g., buddy systems, competitions, rewards) and overcoming common SMI barriers (e.g., transportation). **CONCLUSIONS:** CPSS were willing to facilitate EIM interventions and offered valuable insights on current practices, program feasibility and administration. Findings will aid development of a PA intervention delivered through mental health services to address low rates of PA and reduce health disparities in adults with SMI.

2256 Board #175 May 28 2:00 PM - 3:30 PM
Effects Of Taichi-qigong Exercise On Mental Health Of Nasopharyngeal Carcinoma Survivors

Stanley Sai-chuen Hui, FACSM¹, Parco Ming-fai Siu, FACSM², Grace Yaojie Xie³, Xiaoyue Hu⁴, James Ho-pong Wan¹. ¹The Chinese University of Hong Kong, Shatin, Hong Kong, Hong Kong. ²The University of Hong Kong, Hong Kong, Hong Kong. ³The Hong Kong Polytechnic University, Hong Kong, Hong Kong. ⁴Shanghai University of Sport, Shanghai, China.
 Email: hui2162@cuhk.edu.hk
 (No relevant relationships reported)

The incidence of nasopharyngeal carcinoma (NPC) is high in endemic areas. The long-term chemotherapy and radiotherapy cause bodily dysfunction and extended psychological stress in NPC cancer survivors. The meditative exercise, especially Taichi-Qigong exercise (TQE), are getting more common and continues to grow among cancer survivors. Empirical evidence found positive effects in improving side effects induced by cancer therapy from practicing TQE, however, scientific evidence is still lacking. **PURPOSE:** to evaluate the effects of a 10-weeks TQE, as a non-pharmacological treatment, on mental health of NPC survivors. **METHODS:** 43 NPC survivors (age 32-79 yrs-old; men 45.5%) recruited from the Cancer Patient Resource Centers of a local hospital, were randomly assigned into either a TQE (n=23) or a control group (n=20). The TQE group practiced TQE for at least 3 times a week (one 60-min instructor-led session and two 30-min self-practice sessions) for 10 weeks, whereas control group maintained usual care. Both TQE and control groups received health & diet education once a month. The pre- and post-outcome measures included: questionnaires on cancer-related quality of life (FACT-G), cancer-related fatigue (Brief Fatigue Inventory; BFI), depression (Center for Epidemiologic Studies Depression Scale; CES-D) and sleep quality (Pittsburgh Sleep Quality Index; PSQ). Same measures were obtained 3-months after the intervention (maintenance tests). **RESULTS:** Two-way (group x pre-post) repeated measure ANCOVA with age, gender, and body mass index (BMI) as covariates, found TQE exhibited significant better overall quality of life (FACT-G) ($p \leq .05$), and emotional sub-scale of FACT ($p < .10$). The benefits did not change at maintenance ($p > .05$). The TQE group also demonstrated improved PSQ after intervention ($p < .10$). There were no group difference in BFI and CES-D. ($p > .05$) **CONCLUSIONS:** The present study provides preliminary findings to suggest that, Taichi-Qigong exercise, as a typical mind-body exercise, may contribute to better quality of life, emotion, and sleep quality during the course of NPC rehabilitation. Further study with longer intervention is needed to examine the effects of TQE on other mental health outcomes of cancer survivors such as fatigue and depression, as well as physical health outcomes.

2257 Board #176 May 28 2:00 PM - 3:30 PM
Common Experiences And Beliefs Among Highly Active, Older Adults: Implications For Psychological Satisfaction And Frustration

Danny James McMillian. University of Puget Sound, Tacoma, WA. (Sponsor: Gary McCall, FACSM)
 Email: dmcmillian@pugetsound.edu
 (No relevant relationships reported)

PURPOSE: The prevalence of physical inactivity (PA) has remained largely unchanged in the USA, despite extensive informational campaigns calling for individuals to participate in more PA. Self Determination Theory (SDT) provides a well-researched framework for understanding motivation, and proposes that the satisfaction of three primary psychological needs (autonomy, competence, and relatedness) fuels motivation for physical activity and promotes wellness. This mixed-methods study used SDT to identify experiences and beliefs that affect individual motivation for physical activity in older adults. **METHODS:** The International Physical Activity Questionnaire was used to establish a moderate-high level of PA for all participants (3 males, 2 females; age range: 58-78). The Basic Psychological Needs Satisfaction and Frustration Scale (BPNSFS), and Motives for Physical Activities Measure Revised (MPAM-R) were used along with semi-structured interviews to elucidate the experiences and beliefs of the participants A Wilcoxon signed rank test was used to evaluate BPNSFS data for psychological satisfaction/frustration with the alpha-value set at 0.05. Researchers independently coded interview responses for motivational type (Competence, Social, Interest/Enjoyment, Fitness, Appearance) as well as statements of satisfaction and frustration. MPAM-R data identified motivational priorities and were compared with coding results to establish consistency.

RESULTS: Participants' scores indicated greater life satisfaction than frustration ($p = 0.042$) for each of the three basic psychological needs. Qualitative analysis confirmed predominance of psychological satisfaction, as well as motivation driven by a need for competence, interest, and relatedness. Fitness was the highest scoring motivational construct on the MPAM-R, but was not frequently cited as motivational during the interviews. **CONCLUSIONS:** Active older adults showed greater satisfaction than frustration with the basic psychological needs, suggesting a potential association with moderate-high levels of PA. Motivational factors influencing PA varied among participants, but they shared many common beliefs (e.g., high value of PA and fitness) and experiences (e.g., free play as children).

Trainuvimab: Impact Of High-intensity Exercise On Cognition In Multiple Sclerosis - Interim And Subgroup Analysis

Annette Rademacher¹, Jens Bansi², Niklas Joisten¹, Sebastian Proschinger¹, Marit L. Schlagheck¹, Wilhelm Bloch¹, Max Oberste¹, Alexander Schenk¹, Philipp Zimmer¹. ¹German Sport University Cologne, Cologne, Germany. ²Kliniken-Valens, Rehabilitationsklinik-Valens, Valens, Switzerland.
 (No relevant relationships reported)

Cognitive impairment is a common symptom of Multiple Sclerosis that directly impacts patients' quality of life. Yet, evidence of treatments is mixed. Exercise reveals high potential as a supportive non-pharmacological therapy.

PURPOSE: To investigate the effects of a three-week high-intensity interval training (HIIT) on processing speed, verbal and visual-spatial memory in cognitive impaired persons with MS (pwMS).

METHODS: 66 persons with relapsing-remitting (RR) or secondary-progressive (SP) MS were randomly assigned to an intervention (HIIT: 5x 1.5min intervals at 95-100% HF_{max}, 3x/week) or an active control group (CG: 24min continuous exercise at 65% HF_{max}, 3x/week). For subgroup analysis participants with cognitive impairment were identified (deviation of ≤ 1.5 SD from normative test data from at least one test). Cognitive performance was assessed pre and post to the intervention period with the Brief International Cognitive Assessment for Multiple Sclerosis (BICAMS). Potential within (pre vs. post) - and between -subject (group, MS-type) effects and their interactions were investigated by analysis of variance (ANOVA) with repeated measures. Post-hoc tests (Bonferroni) were conducted for significant main effects of within or between-subjects.

RESULTS: 28 pwMS were identified as cognitively impaired. ANOVA revealed no significant interactions for any outcome and showed no significant main effects for visual-spatial memory. Significant main effects (factor time) were observed for processing speed ($F(1, 24)=15.65, p=.001$) and verbal memory ($F(1, 24)=4.85, p=.037$). In the HIIT-group participants with RRMS significantly improved processing speed over time (MD: -4.67, 95%-CI [34.41, 43.81], $p=.023$), whereas no changes ($p=.051$) were shown for participants with SPMS. No improvements were observed for the CG. Pairwise comparisons revealed no significant changes for verbal memory.

CONCLUSION: Compared to the CG, HIIT shows stronger impact on processing speed for RRMS. SPMS-type showed no changes. However, results should be interpreted cautiously, as the data set reveals no significant main effects for group and MS-phenotypes.

Effect Of A Multicomponent Exercise Program On Functional Capacity And Cognitive Function In Frail Community Elders With Cognitive Decline

Antonio García Hermoso¹, Fabricio Zambom-Ferraresi¹, Itxaso Marín-Epelde², Mikel López Sáez de Asteasu¹, Juan Luis Sanchez-Sanchez¹, María Fernanda Ramón², Iván Antón³, Nicolás Martínez-Velilla¹, Mikel Izquierdo⁴, Robinson Ramírez-Vélez¹, Alvaro Casas-Herrero². ¹Fundación Miguel Servet - Navarrabiomed, Pamplona, Spain. ²Complejo Hospitalario de Navarra, Pamplona, Spain. ³Fundación Matia Hospital Bermingham, Pamplona, Spain. ⁴Public University of Navarra, Pamplona, Spain.
 (No relevant relationships reported)

PURPOSE: Both frailty and mild cognitive impairment are prevalent issues among the geriatric population but have traditionally been evaluated on separate terms. Given the growing evidence that these two conditions might share a biological substrate, interventions aiming to improve physical function might as well induce benefits on cognitive function. The main objective was to test the effect of a multicomponent

exercise program (VIVIFRIL) on both domains in frail and pre-frail patients (according to Fried criteria) with evidence of mild cognitive impairment or mild dementia (Reisberg GDS 3 and 4).

METHODS: We performed a preliminary analysis of 96 recruited patients (mean age 83±5) from three Spanish hospitals (San Sebastian, Pamplona and Getafe). Subjects were randomized to a control or an intervention group, the last one undergoing a 12-week multicomponent exercise program (VIVIFRIL). Changes in functional capacity were evaluated through Short Physical Performance Battery (SPPB), one leg press repetition maximum strength (1-RM) and Barthel index, and those in cognitive function with the Montreal Cognitive Assessment test (MOCA), verbal fluency and the Mini Mental State Examination (MMSE).

RESULTS: Significant improvement was found in the following variables: SPPB improved in 1.14 points (p=0.002), 1-RM improved in 12 points (p=0.035), MOCA test improved in 3.32 points (p=0.033) and verbal fluency improved in 2 points (p=0.028) in the intervention group versus the control group.

CONCLUSIONS: A multicomponent exercise intervention program using the VIVIFRIL methodology improves both functional capacity and cognitive function in frail and prefrail elderly patients who exhibit mild cognitive impairment and mild dementia.

Exercise Is Associated With Decreased Fracture Odds In Young Adults With Attention Deficit Hyperactivity Disorder

Mansour Mohammed Alotaibi, Carmen E. Capo-Lugo, Suzanne E. Perumean-Chaney, Harshvardhan Singh, Donald H. Lein. *University of Alabama at Birmingham, Birmingham, AL.*
 Email: amansour@uab.edu

(No relevant relationships reported)

Young adults with Attention Deficit Hyperactivity Disorder (ADHD) have higher fracture rates than healthy adults. While exercise is recommended for people with ADHD to alleviate hyperactivity-impulsivity, little is known about the relationship between exercise and fracture in this population. **PURPOSE:** To explore the association between exercise and fractures in young adults with ADHD, not using medication. **METHODS:** We performed a retrospective analysis of data of young adults with ADHD treated at the University of Alabama at Birmingham Health Systems. We selected a case if an individual was previously diagnosed with ADHD using ICD-10 code F90 and ages between 21 and 35 years. The comparison group were individuals with ADHD and have not had a fracture within the same age limits. The outcome variable was whether a patient with ADHD diagnosed with a fracture or not during this period. Exercise files included data about exercise status (i.e., yes or no), frequency (i.e., low, moderate, or high), and type (i.e., aerobics or non-aerobics). Exercise assessment was within the year before the fracture date for fracture group and within the year before data acquisition for the non-fracture group. We ran a multivariable logistic regression analysis to test the association between fractures and 1) exercise status, 2) exercise frequency, and 3) exercise type, controlling for sex. We analyzed the data using STATA SE 15.1. **RESULTS:** Our analyses included 296 persons with a mean age of 27.29 ± 4.17 years for the comparison group and 28.0 ± 3.58 years for the fracture group. The mean age of fracture in the fracture group was 25.09 ± 3.45. Also, the logistic regression that was controlled for sex, showed that individuals who exercised had significantly lower odds of having a fracture compare to those that reported no exercise [OR: 0.14, 95% CI: 0.08, 0.27]. Of those, females compared to males, were also significantly associated with sustaining fewer fractures, controlling for exercise status [OR: 2.86, 95% CI: 1.53, 5.35]. Finally, exercise frequency and exercise type were not significantly associated with fracture risk. **CONCLUSIONS:** Engaging in exercise might decrease the odds of sustaining a fracture in young adults with ADHD. Exercise needs to be studied more in young adults with ADHD to determine how exercise may protect against fractures.

 (No relevant relationships reported)

Chronic kidney disease (CKD) associates with earlier onset of cognitive impairment. Physical activity (PA) improves neuronal plasticity and cognitive function among older adults. However, limited data exist exploring the effect of PA on cognitive function in CKD patients. **PURPOSE:** To investigate the effect of regular physical activity on cognitive function in CKD patients. **METHODS:** We analyzed 68 patients with CKD admitted to a Midwestern hospital between January 2017 and

July 2018. All subjects provided a health history, had a comprehensive metabolic panel with estimated glomerular filtration rate (eGFR), and reported whether they engaged in regular physical activity (PA). Cognitive impairments, including dementia, Alzheimer's, and Parkinson's disease were documented. Independent-samples t-tests and chi-squared tests compared patient profiles between sedentary and active patients. Logistic regression analyses tested the effect of PA on cognitive impairments holding constant other significant predictors. **RESULTS:** Patients were 64.7 ± 17.4 years old, had an eGFR of 24.7 ± 13.8 mL/min, 66.2% were sedentary, and 25.0% had a cognitive impairment. Older subjects were more likely to have a diagnosis of cognitive impairment (p=0.051) and the prevalence was higher in sedentary patients (33.3%) than in those who were physically active (8.7%; p=0.026). Holding constant the age of the patient and the stage of CKD, engagement in PA shared a trending association with mental impairment (p=0.056), predicting a 79.8% reduction in the likelihood of diagnosis (Pseudo R² = 0.187; 95% CI of OR: 0.039 to 1.040). Similarly, controlling for eGFR rather than CKD stage, the significance of PA as a predictor remained stable (p=0.057; 95% CI of OR: 0.039 to 1.052). **CONCLUSIONS:** Patients with CKD experience a higher risk of cognitive impairment than age-matched controls. In our sample, engagement in regular physical activity demonstrated a protective effect, and sedentary behavior influenced diagnosis more than age.

Exercise And Geriatric Depression: A Scoping Review Of The Research Evidence

Samira Mehrabi, Laura Middleton. *University of Waterloo, Waterloo, ON, Canada.*
 Email: samira.mehrabi@uwaterloo.ca
 (No relevant relationships reported)

Geriatric depression is a common late-life mental health disorder that increases morbidity and mortality. It has been shown that exercise is effective in alleviating symptoms of geriatric depression. However, inconsistencies across studies and lack of optimal dose-response of exercise for improving geriatric depression have made it challenging to draw solid conclusions on the effectiveness of exercise in late-life depression. **Purpose:** To further investigate the moderators of the effectiveness of exercise on geriatric depression across the current body of evidence. **Methods:** Based on the Arksey and O'Malley framework, an extensive search strategy was performed by exploring PubMed, Scopus, Sport Discus, PsycInfo, ERIC, and IBSS without limitations in the time frame. Eight systematic reviews with empirical results and evaluated the effect of exercise on depression among people aged 60 years and older were identified, and their individual studies were screened for inclusion. One additional study was found through the hand searching of reference lists. After full-text screening and applying inclusion and exclusion criteria, 21 studies were retained. **Results:** The review revealed high variability in characteristics of the exercise interventions and outcome measures. Sample characteristics, nature of comparators, main outcome assessment, and baseline severity of depression also varied notably. Mind-body and aerobic exercises were found to significantly reduce geriatric depression. However, results on the relationship between resistance training and improvements in geriatric depression were inconsistent, and results of the intensity-related antidepressant effects of exercise interventions were mixed. Extensive use of self-reported questionnaires for the main outcome assessment and lack of evidence on the relationship between depression severity and observed effect were of the other important highlights of the review. **Conclusion:** Several literature gaps were found regarding the potential effect modifiers of exercise and geriatric depression. While acknowledging the complexity of establishing recommendations on the exercise variables and geriatric depression, future studies are required to understand the threshold effect of exercise for treating geriatric depression.

Effect Of 1 Year Of Qigong Exercise On Cognitive Function Among Older Chinese Adults

Jing Jin, Yin Wu, Shaohua Li, Suhui Jin, Chenglin Zhou, Zhen Wang. *Shanghai University of Sport, Shanghai, China.*
 Email: jinjing@sus.edu.cn
 (No relevant relationships reported)

Objectives. To compare the effectiveness of a tailored qigong exercise versus stretching and toning exercises in the maintenance of cognitive abilities in Chinese elders at risk of cognitive decline. **Design.** A 1-year, single-blind, cluster randomized controlled trial. **Method.** Seventy-four older Chinese adults with risk of cognitive decline were enrolled in the study. They were cluster randomized to the qigong group and to the stretching and toning control exercise group. Cognitive and functional performance were assessed at baseline and at 1 year as measured using the Chinese version of Montreal Cognitive Assessment-Basic (MoCA) test and the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). **Results.** At 1 year, 25 of 33 participants (75.8%) in the qigong group and 26 of 33 participants (78.8%) in the control group completed the exercise intervention. A bivariate correlation test indicated a good correlation between the MoCA test score and the

RBANS total score after the intervention ($r = 0.517, p < 0.01$). Generalized estimating equations revealed that those in the qigong group had lower risk of progression of cognitive decline at 1 year (odds ratio, 0.314; 95% confidence interval, 0.103-0.961; $p = 0.04$). Two-way repeated-measures analyses of variance followed by post hoc t -tests with Bonferroni corrections indicated that performances on the MoCA test and the RBANS were significantly better in the qigong group than in the control group for the MoCA score ($p < 0.01$) and the RBANS cognitive domains of global cognition ($p < 0.01$), memory ($p < 0.01$), visuospatial/construction ($p < 0.01$), and language ($p < 0.01$) abilities, but not for attention ($p > 0.05$). **Conclusions.** Performance of qigong for 1 year was significantly superior to stretching and toning exercises not only for preventing progression of cognitive decline but also for improving several cognitive functions among older Chinese adults at risk of cognitive decline.

A 6-week Aquatic Exercise Improve Accelerometer-measured Sleep Efficiency Among Adults With Chronic Musculoskeletal Pain

Billy Chun Lung So. *The Hong Kong Polytechnic University, Hong Kong, Hong Kong.*
 Email: billy.so@polyu.edu.hk
 (No relevant relationships reported)

To investigate the effect of a 6-week moderate-intensity aquatic exercise program on sleep efficiency, sleep quality, pain, stress and physical activity among adults. **METHODS:** A quasi-experimental trial was conducted with a sample of 30 adults with chronic musculoskeletal pain, assigned to two groups (Intervention Group and Control Group). Subjects were recruited by convenience sampling through a community physiotherapy Centre in Hong Kong. Subjects allocated to the intervention group followed a structured, 6-week, bi-weekly, 60-minute aquatic exercise program. The 12 sessions were supervised by a qualified aquatic fitness instructor in a 20x10m pool with water temperature controlled. Six exercises were performed in each session with one old exercise replaced by a new one in each session. During the session, heart rate and RPE were monitored. Control Group was reminded to not change their exercise habits or medication regimen. Data regarding sleep efficiency by ActiGraph, sleep quality by Chinese version of the Pittsburgh Sleep Quality Index (CPSQI), pain by numeric pain rating scale were collected before and after the 6-week aquatic exercise program. Data were analyzed with SPSS 25 and a p -value less than 0.05 indicated statistical significance of results. **RESULTS:** No statistically significant differences on all demographic data and outcome measures between intervention and control group in the baseline measurement, except there was significantly higher average BMI ($p \leq 0.05$) and fewer total true sleep hours ($p \leq 0.001$) in intervention group. Significantly longer total true sleep time (27 minutes, $p \leq 0.01$), greater sleep efficiency (3% improvement, $p \leq 0.01$), less pain ($p \leq 0.05$) and better sleep quality ($p \leq 0.05$) were found in intervention group. Significant group-time interaction found only in total true sleep time ($p \leq 0.001$). **CONCLUSION:** Aquatic exercise has been proven effective in improving sleep. From the within-group pre-post result, it shows that there is a statistically significant improvement in term of sleep efficiency and reduction of pain. This study helps to extend the work by studying the effect of aquatic-based exercise on adults with chronic musculoskeletal pain.

Meta-analysis of Ba Duanjin in the treatment of insomnia
 Abstract:

Objective: Insomnia is the most common diseases. Long-term insomnia can seriously affect normal life , even lead to a serious accident. Ba Duan Jin is a traditional Chinese exercise, which can regulate meridians qi -blood-body fluid, and improve the quality of sleep. This article comprehensively evaluates the effect of Ba Duan Jin on insomnia by meta-analysis.

Methods: Searching Wanfang platform, VIP consulting platform , CNKI, Pubmed and Springer on Ba Duanjin in the treatment of insomnia Randomized controlled trial (RCT) . Meta-analysis was performed using revman5.3 software. The main indicators were the number of recovered patients ,effective patients and invalid patients, the Pittsburgh sleep quality score (PSQI).

Results: A total of 98 articles were retrieved by searching in computer . Excluding the literature which is repeated or with incomplete date , the final including was 9 RCT.A total of 789 patients were included in the analysis. Meta-analysis showed that the number of patients with recovery was higher in the experimental group than in the control group. [OR=3.14, 95% CI (2.18, 4.52), $p < 0.00001$], and the number of invalid

patients was lower. [OR=0.19 , 95% CI (0, 12, 0.31), $p < 0.00001$], the difference was statistically significant. There was no statistical difference between the effective groups. PSQI were not statistically different due to excessive heterogeneity. **Conclusion:** This meta-analysis showed that in the treatment of insomnia, the clinical efficacy of the group with Ba Duan Jin intervened was better than the group with the conventional drug, and the difference was statistically significant.

The Effect Of Brief Mindfulness Intervention As Adjuvant Of Fluid Intake On Athletes' Cognitive Function

Yuxin ZHU¹, Fenghua SUN¹, Chunxiao LI², Hungkay CHOW¹.
¹The Education University of Hong Kong, Hong Kong, China.
²Nanyang Technological University, Singapore, Singapore.
 Email: s1114219@s.eduhk.hk
 (No relevant relationships reported)

PURPOSE: The present study investigated the effect of combined fluid intake and brief mindfulness intervention (MBI) in a simulative half-time break of soccer competition on athletes' cognitive function.

METHODS: In a 3 (treatments) \times 2 (times) double-blinded cross-over design, fourteen male athletes (age: 24.3 \pm 3.7 yr, height: 173.8 \pm 4.5 cm, weight: 68.3 \pm 5.1 kg, VO_{2max} : 47.0 \pm 4.4 ml/kg/min) received three treatments (Control: non-carbohydrate (CHO) electrolyte solution + traveling introduction audio; CHO: CHO-electrolyte solution + travelling introduction audio; and CHO_M: CHO-electrolyte solution + MBI) in a simulative half-time break. Cognitive function performance (assessed by Stroop Test, Corsi Block Test, Rapid Visual Information processing task (RVIP)), mindfulness level, blood glucose and lactic, rating of perceived exertion was tested at different time points during the trial.

RESULTS: Major findings include: (1) CHO_M trial obtained a better score in post Stroop colour test when compared with Control trial (CHO_M vs. Control: 17813.87 \pm 3706.98 vs. 22990.43 \pm 6665.36; $p = .04$); (2) a significant interactive effect was observed on the performance of Corsi block test ($p = .03$). Specifically, the reaction time decreased from pre-trial to post-trial in CHO_M and Control trials (pre vs. post: 826.88 \pm 384.67 vs. 667.49 \pm 331.56 ms, $p < .01$ for CHO_M; pre vs. post: 1085.43 \pm 388.51 vs. 798.36 \pm 253.28 ms; $p < .01$ for Control), but not in CHO trial (pre vs. post: 832.68 \pm 296.37 vs. 810.11 \pm 347.70 ms, $p = .66$); (3) CHO trial spent less time on missing numbers in post RVIP test than the other two trials (Control vs. CHO vs. CHO_M: 5939.57 \pm 2100.27 vs. 3316.79 \pm 2716.73 vs. 6201.43 \pm 4013.58 ms; $p = .03$), given that their performance in pre-test were statistically the same ($p = .13$).

CONCLUSIONS: In conclusion, a positive effect of the combined fluid intake and brief MBI on athlete's cognitive function was revealed, while both positive and negative effect was revealed for fluid intake only.

Preschoolers Demonstrate Similar Learning And Enhanced On-task Behavior Following Physically-active Lessons On Emerging Numeracy Skills

Amanda L. McGowan, Grace M. Mansour, David P. Ferguson, Hope K. Gerde, Karin A. Pfeiffer, FACSM, Matthew B. Pontifex. *Michigan State University, East Lansing, MI.*
 Email: mcgowaw78@msu.edu
 (No relevant relationships reported)

Previous studies demonstrate variable effects of physically-active instruction on academic achievement and classroom behavior. The utility of such approaches to train the approximate number system—a foundational construct underlying later mathematics achievement—in preschoolers remains unclear.

PURPOSE: To determine the acute effects of physically-active lessons on acuity of the approximate number system and on-task behavior in preschoolers.

METHODS: Using a randomized within-participants repeated-measures crossover design, children ($N = 51$; 3-5 y) completed a computerized approximate number system task before and after engaging in either 20-min of either physically-active or conventional sedentary instruction during two separate, counterbalanced sessions. The conventional sedentary lessons consisted of activities previously shown to strengthen approximate number representations (i.e., number line estimation, counting, and magnitude estimation) at an intensity of approximately 12% heart rate reserve whereas the physically-active lessons consisted of comparable activities integrated with

movement corresponding to 30% heart rate reserve. Separate univariate multi-level models were constructed. Difference in pedometer step count between conditions was analyzed using independent t-test.

RESULTS: Although no significant differences were observed in behavioral task performance at posttest between conditions, $F_s(2,49) \leq 1.0, p_s \geq 0.434, f^2_s < 0.02$ [95% CI: 0 to 0.08], fewer experimenter redirections were required following the physically-active lessons (2.5 ± 2.8) relative to following the conventional sedentary lessons (5.0 ± 3.6), $F(1, 49) = 20.7, p < 0.001, f^2 = 0.61$ [95% CI: 0.24 to 1.29]. On average, children accrued 931.3 ± 8.2 more steps during the physically-active lessons relative to the sedentary lessons, $t(95) = 19.1, p < .001, d_s = 3.91$ [95% CI: 3.19 to 4.55].

CONCLUSION: Physically-active lessons on emerging numeracy skills do not impede training of the approximate number system and result in greater on-task behavior relative to conventional sedentary lessons in preschoolers. Future studies should explore the integration of such approaches into early childhood education.

Funding: Supported by funds from the Department of Kinesiology at Michigan State University.

History Of Heading In Soccer Impairs Cognition But Not Cerebral Perfusion In Young Amateur Players

Christopher James Marley, Thomas S. Owens, Hayato Tsukamoto, Trevor Harris, Ryan Cutting, Adam Jones, Damian M. Bailey. *University of South Wales, Pontypridd, United Kingdom.*

Email: chris.marley@southwales.ac.uk
 (No relevant relationships reported)

Heading the ball in soccer has been linked to impaired cognition and may increase the risk of neurodegenerative disease. This may be explained by an accelerated decline in cerebral perfusion, a major risk factor for cognitive impairment, stroke and dementia, for reasons that remain unclear.

Purpose To determine if a history of recurrent heading of a football predisposes to cerebral hypoperfusion and cognitive impairment.

Methods Twenty-nine amateur male soccer players (age: 28 ± 6 yrs) with a playing history of 15 ± 6 yrs and a self-reported heading frequency of 9 ± 4 balls per game were recruited for the study. They were compared to 32 age and fitness-matched controls who had not participated in contact sports with no history of concussion. All participants completed a battery of psychometric tests that assessed learning and memory (Rey-Auditory Verbal Learning Test), working memory (Repetition of Digits Backwards; Trail Making Test B) and attention and information processing (Repetition of Digits Forwards; Trail Making Test A; Digit Symbol Substitution Test). A sample of the soccer players ($n = 13$) and controls ($n = 22$) also completed a cerebrovascular screening whereby middle cerebral artery velocity (MCAv) and mean arterial blood pressure (MAP) were assessed using transcranial Doppler ultrasound and finger photoplethysmography, respectively. Cerebrovascular conductance/resistance were calculated as MCAv/MAP and MAP/MCAv.

Results Soccer players were characterized by impaired learning and memory, and attention and information processing compared to controls ($P < 0.05$; Table 1). However, no between group differences were observed in MCAv, CVC or CVR between groups ($P > 0.05$; Table 1).

Conclusion Heading the ball in soccer is associated with impaired cognition that appears to be independent of cerebral hypoperfusion.

Table 1. Cognitive function and cerebral perfusion

	Controls	Soccer Players	P Values
MCAv (cm.s ⁻¹)	59 ± 12	61 ± 10	0.587
MAP (mmHg)	88 ± 20	90 ± 11	0.620
CVC (cm.s ⁻¹ .mmHg)	0.71 ± 0.20	0.69 ± 0.15	0.959
CVR (mmHg.cm.s ⁻¹)	1.49 ± 0.32	1.51 ± 0.33	0.922

Exercise Affect And Cardiac Vagal Tone: A Psychophysiological Connection

Allyson G. Box, Steven J. Petruzzello, FACSM. *University of Illinois Urbana-Champaign, Urbana, IL.* (Sponsor: Steven J. Petruzzello, FACSM)

(No relevant relationships reported)

INTRODUCTION: Evidence suggests vagal tone may be a viable physiological marker of exercise readiness and recovery. However, whether vagal tone is associated with feeling states (i.e., affect) prior-to, during, and following exercise is poorly understood. Consistent with psychological hedonism, individuals will pursue exercise that elicits pleasure while avoiding displeasure. Thus, it is of interest whether an index of physiological readiness is associated with dis/pleasure while engaging in high-intensity interval exercise. **PURPOSE:** Explore the psychophysiological relationship between reactivity and recovery of phasic vagal tone and affect occurring during high-intensity interval exercise (HIIE). **METHODS:** Participants (N= 25, 13 females, 23.3±4.0 yrs) completed a 20-minute session of HIIE (5-blocks of 3-min exercise to 1-min rest) where vagal tone (i.e., High Frequency Power) and affect (via Feeling Scale) was recorded prior to, during (vagal tone recorded during rest-intervals), and up to 15-min post-exercise. **RESULTS:** Prior to exercise, vagal tone (6.5 ± 1.6) and affect (2.4 ± 1.4) were positively related ($r = 0.58$). Upon HIIE initiation, both vagal tone and affect significantly declined during Block 1 ($1.6 \pm 1.7, P < 0.001; 1.7 \pm 2.0, P < 0.001$, respectively). Vagal tone remained withdrawn (Rest-2: $1.2 \pm 1.5; R3: 0.8 \pm 1.5; R4: 1.3 \pm 1.5; P_s > 0.05$) until post-15 (4.1 ± 2.9). Affect significantly declined during each exercise block (Block 1Δ: $-0.6; B2Δ: -0.7; B3Δ: -1.1; B4Δ: -1.6; B5Δ: -1.0; P_s < 0.05$), but also significantly increased following each rest-interval (Rest-1Δ: $+0.4; R2Δ: +0.5; R3Δ: +0.7; R4Δ: +1.3; P_s < 0.05$), with post-15 affect (3.0 ± 1.9) significantly exceeding pre-affect ($P < 0.01$). Time-lagged correlations suggested small-to-moderate relationships between vagal tone and affect during the HIIE ($r_s = 0.22-0.47$), with a disconnection at post-15 ($r = -0.03$). **CONCLUSIONS:** As expected, participants experienced vagal tone withdrawal at HIIE initiation and a decline in pleasure during high-intensity exercise blocks, with affective rebounds during recovery. This suggests vagal tone can be a psychophysiological marker of affective readiness and displeasure experienced during exercise, but not as an index of affective recovery.

The Effect Of Mind-body Exercise On Working Memory: Differences Between Experts And Novices

Yuan Yang, Chongwen Zuo, Shoufu Yan. *Capital University of Physical Education and Sports, Beijing, China.*

Email: yangyuan.0115@foxmail.com
 (No relevant relationships reported)

BACKGROUND: Working memory is one of the sub-abilities of executive function and plays an important role in the entire cognitive process. However, working memory decline in aging seriously impairs the living ability of older people. Therefore, how to mitigate the decline of working memory function in older adults has become a focal point of current research. Mind-body exercise (MBE) is considered an effective

way to delay cognitive decline in older adults, but the effects of MBE on working memory function and mechanisms by which MBE may improve cognition in older adults remain unknown. **PURPOSE:** This study explores whether long-term MBE will influence working memory function by comparing MBE experts with novices. These findings will provide theoretical and empirical basis for maintaining the cognitive function of older people. **METHODS:** A total of 39 healthy older people (all female, mean age = 65.23 ± 2.43 years) from a community in Beijing participated in this experiment. 13 subjects in the Tai Chi group (TC) experienced more than 5 years of TC exercise. 13 subjects in the Baduanjin group (BD) experienced more than 5 years of BD exercise, and 13 subjects without systematic MBE were assigned to the control group. Each participant was administered the N-back task to evaluate working memory function. The primary outcome was reaction time (RT) and accuracy rate (AR) for the N-back task. **RESULTS:** the TC group and BD group had faster RT for N-back task compared with the novice group ($p < 0.05$). The RT of the BD group was faster than the TC group, but the difference was not significant ($p > 0.05$). The TC group and BD group had higher AR for the N-back task compared with the novice group ($p < 0.05$). The AR of TC group was higher than BD group, but the difference was not significant ($p > 0.05$). **CONCLUSION:** Different BMEs are beneficial to the working memory function of the elderly. Compared with the novices, long-term BME can significantly improve the working memory function of older adults, which is an effective exercise to maintain the cognitive function of the elderly.

 Email: apaul8@radford.edu
 (No relevant relationships reported)

PURPOSE: Dual-tasking refers to concurrent performance of two physical or mental tasks. Considering the critical role of dual-tasking in daily life, it is important to develop interventions to improve its efficiency or slow down its decline with age or disease. The specific purpose of this research was to study the effects of single bouts of a moderate-intensity (MI) or high-intensity interval training (HIIT) exercise on the efficiency of the extended cognitive Timed Up and Go (ETUGcog) test, which involves concurrent performance of physical and mental tasks.

METHODS: 17 males and females aged 23-35 years underwent two different single bouts of exercise sessions, a HIIT and a MI, on separate occasions, based on established protocols. Each session began with ETUGcog prior to exercise as pre-test. ETUGcog involves simultaneous performance of an extended version of Timed Up & Go test (the physical task), while counting backwards by sevens starting from a given number (the mental task). The post-tests were administered immediately after the exercise when the subject cooled down to 10% above resting HR (10%aHR), and 24 hours later. The test parameters that were recorded are the number of correct responses while counting backwards until test completion, and time to complete test.

RESULTS: Correct responses after a HIIT session were significantly higher than pre-test responses when tested at 10%aHR (5.18 ± 1.43 vs 4.24 ± 1.82 , $p = 0.02$), and 24 hours later (5.82 ± 2.24 vs 4.24 ± 1.82 , $p = 0.002$). No such improvements were seen after a MI session, as correct post-test responses at 10%aHR (5.18 ± 2.98) and 24 hours later (5.06 ± 2.75) were similar to pre-test responses (4.79 ± 2.47), with $p > 0.05$ in both paired comparisons. Also, the times to complete ETUGcog tests were not significantly different when comparing the pre-test to both post-test times, with $p > 0.05$, in both types of exercise sessions.

CONCLUSIONS: A single bout of high-intensity, but not moderate intensity exercise, might improve dual-tasking efficiency by increasing cognitive processing speeds, without delaying activity completion times, and improvements can last a full day. This could be due to neuroplastic improvements in brain's cognitive areas in the prefrontal cortex, caused by blood flow increases sufficient with high intensity, but not with lower intensity exercise.

Effects Of Acute Caffeine Ingestion Following A Period Of Sleep Loss On Cognitive And Physical Performance: A Systematic Review And Meta-analysis

Christopher Irwin¹, Saman Khalesi², Ben Desbrow¹, Danielle McCartney³. ¹Griffith University, Gold Coast, Australia. ²Central Queensland University, Brisbane, Australia. ³The University of Sydney, Sydney, Australia. (Sponsor: Prof. Louise Burke, FACSM)
 Email: c.irwin@griffith.edu.au
 (No relevant relationships reported)

PURPOSE: This systematic review and meta-analysis examined the impact of acute caffeine consumption on cognitive and physical performance in sleep deprived/

restricted individuals. **METHODS:** Electronic databases were searched for studies measuring cognitive and/or physical performance following *sleep restriction* (≤ 6 h sleep within 24h) or *deprivation* (≥ 24 h wakefulness) under control (placebo) and intervention (caffeine) conditions. Studies were included if performance was assessed within 6h of caffeine consumption. Individual effect estimates (EEs) were calculated as Hedges' g for independent groups. Random effects meta-analyses were performed to determine intervention efficacy. Statistical significance was attained if the 95% CI did not include zero. Multiple meta-regression analysis was conducted to determine effects of caffeine dose and period of wakefulness on the magnitude of the effect. **RESULTS:** 36 publications providing 250 EEs were included. Caffeine improved performance on reaction time tasks (12 EEs; $g = 1.11$; 95% CI: 0.75-1.47) and both response time (44 EEs; $g = 0.86$; 95% CI: 0.53-0.83) and accuracy (27 EEs; $g = 0.68$; 95% CI: 0.48-0.88) on attention tasks. The magnitude of the effect increased as caffeine dose increased, but was not influenced by the period of wakefulness for either task. Caffeine improved executive function (38 EEs; $g = 0.35$; 95% CI: 0.15-0.55) and the magnitude of the effect increased as caffeine dose increased ($p = 0.007$) and period of wakefulness decreased ($p = 0.021$). Caffeine also improved response time (20 EEs; $g = 1.95$; 95% CI: 1.39-2.52) and accuracy (34 EEs; $g = 0.43$; 95% CI: 0.30-0.55) on information processing tasks, but neither caffeine dose ($p = 0.785$) nor period of wakefulness ($p = 0.373$) influenced the magnitude of the effect. No other performance outcomes were appropriate for meta-analysis. However, studies typically indicated a benefit of caffeine on memory (25 EEs), crystallized intelligence (11 EEs) and physical (39 EEs) performance. **CONCLUSION:** Caffeine is an effective counter-measure to the cognitive and physical impairments associated with sleep loss.

 (No relevant relationships reported)

Research has demonstrated higher cognitive abilities are often linked to physical activity participation. **PURPOSE:** To examine the impact that 45 minutes of daily physical education on the aerobic capacity and perceptual speed of elementary school children. **METHODS:** An analysis of variance (ANOVA) mixed effect linear model was used to evaluate the effectiveness of 45 minutes of daily physical education on fitness and perceptual speed among youth in grades 6th-8th attending Legacy Early College, a Title I school in the southeastern US. Gain scores (final post-test assessment in May 2019 - original pre-test assessment in September 2017) were calculated and analyzed for significance. The interaction between school and time was estimated for each outcome. Each analysis was stratified by gender and adjusted by age to control for baseline differences by school. A Title I control school that provided physical education once per week was utilized as a comparison. **Summary of RESULTS:** Legacy Early College children significantly improved on perceptual speed compared to controls. A significant gain increase at post-test for sections 1, 2, 3 and the Total score ($p = .002$ $F = 9.27$, $p = .020$ $F = 5.45$, $p = .019$ $F = 5.54$, $p = .003$ $F = 9.17$) respectively, was found. Legacy females had significant gains for sections 1 and 2 compared to controls ($p = .041$ $F = 4.25$, $p = .010$ $F = 6.68$). Legacy males had a similar trend with significantly higher gains for sections 1, 3, and Total ($p = .041$ $F = 4.26$, $p = .030$ $F = 4.80$, $p = .038$ $F = 4.38$) compared to controls. Additionally, Legacy children improved significantly on PACER laps compared to controls (8.64 vs. 2.08; $p = 0.000$, $F = 23.77$) over time. Legacy females had significantly higher gains in PACER laps compared to controls ($p = 0.000$, $F = 34.30$). Legacy males also had significant gains in PACER laps over time compared to controls ($p = .010$ $F = 6.86$). **CONCLUSIONS:** 45 minutes of daily physical education led to increases in fitness and processing speed over time. Baseline Cognitive Performance Moderates The Benefits Of Regular Exercise On Cognition In Children

Keita Kamijo¹, Toru Ishihara², Eric S. Drollette³, Sebastian Ludyga⁴, Charles H. Hillman⁵. ¹University of Tsukuba, Tsukuba, Japan. ²Hokkaido University, Sapporo, Japan. ³University of North Carolina Greensboro, Greensboro, NC. ⁴University of Basel, Basel, Switzerland. ⁵Northeastern University, Boston, MA.
 Email: ktakamijo@gmail.com
 (No relevant relationships reported)

Although a growing number of studies have examined the effects of regular exercise on cognition and academic performance in children, the findings have remained controversial due to divergent experimental approaches. **PURPOSE:** The present study investigated baseline cognitive performance as a moderating factor underlying the effects of regular exercise intervention on cognition, with the goal of determining whether baseline variance may account for the lack of consensus in the literature.

METHODS: We reanalyzed data from three randomized controlled trials in which the effects of regular exercise intervention on cognition were examined using executive function tasks (e.g., flanker task), with a cumulative total of 292 participants (9-13 years). To test the moderation effects of baseline performance on the relationship between exercise intervention and changes in cognitive performance, we used hierarchical generalized multiple regression analysis predicting pre-post changes in cognitive performance. **RESULTS:** Results indicated that the beneficial effects of regular exercise intervention on cognitive performance were greater in lower baseline performers. Additionally, the pre-post changes in cognitive performance did not differ between the control and intervention groups, even for high baseline performers. **CONCLUSIONS:** These findings suggest that baseline cognitive performance is an individual difference variable that moderates the effects of regular exercise intervention on changes in cognition. Thus, future studies should account for baseline cognitive performance when examining the exercise - cognition relationship. The present study also supports recent views that increased time spent in physical exercise does not detract from cognitive performance and academic achievement in children. Supported by NICHD Grant R01 HD055352 and the Gottfried and Julia Bangerter-Rhyner-Foundation (8472/HEG-DSV).

The Effects Of High-altitude Mountaineering On Cognitive Function In Mountaineers: A Meta-analysis
 Lun Li¹, ShiSi Zou¹, Yong'Tai' Wang, FACSM². ¹China University of Geosciences (Wuhan), Wuhan, China. ²The University of Texas at Tyler, Tyler, TX.
 Email: lilun@cug.edu.cn
 (No relevant relationships reported)

PURPOSE: Nowadays, high altitude mountaineering is increasingly popular among different populations with a dream to challenge high-altitude exercises facilitated by the convenience of global traveling. In view of this, the authors performed a meta-analysis in the hope of finding the effects of high-altitude mountaineering on cognitive function in mountaineers prior to and after the climbing.

METHODS: After a thorough electronic literature search and selection, eight studies were included in this meta-analysis, and test cycle ranged from 8 to 140 days. The eight variables included in this meta-analysis were: trail-making test part B (TMB), finger tapping test-left (FTL), finger tapping test-right (FTR), digit span test forward (DSF), digit span test backward (DSB), wechsler memory scale visual (WMSV), aphasia screening test-visual motor errors (AST-vis), aphasia screening test-verbal items (AST-ver). The effect sizes and Forest Plots of these eight variables were generated. **RESULTS:** Five variables (trail-making test part B (TMB), ES = 0.39; digit span test forward (DSF), ES = 0.57; finger tapping test-right (FTR), ES = 0.50; finger tapping test-left (FTL), ES = 0.16; wechsler memory scale visual (WMSV), ES = 0.63;) out of eight were significantly improved after high-altitude mountaineering, while ES values of digit span test backward (DSB), aphasia screening test-verbal items (AST-ver) and aphasia screening test-visual motor errors (AST-vis) did not show significant improvement after the mountaineering.

CONCLUSIONS: Our findings have some limitations arising from methodological issues inherent in the meta-analysis and we could not explain the high heterogeneity between studies. Despite such limitations, the current study has the strength of being the first meta-analysis trying to specify cognitive function of mountaineers compared with before and after high-altitude mountaineering. High-altitude mountaineering, as a short-term plateau exercise, has no significant negative impact on the cognitive function of climbers. Future research is needed for a long period of high-altitude mountaineering.

Excess Body Mass Attenuates The Effects Of Acute Exercise On Preadolescent Brain Function And Cognition
 Nicole E. Logan, Lauren B. Rain, Jennifer N. Hunt, Arthur F. Kramer, Charles H. Hillman. *Northeastern University, Boston, MA.*
 Email: logan.n@husky.neu.edu
 (No relevant relationships reported)

Purpose

This study investigated the transient effects of an acute bout of aerobic exercise and excess body mass on cognitive and brain function in preadolescent children.

Methods

Thirty-nine children (8-10yrs; 16 females) completed baseline and demographic questionnaires, and dual-energy X-ray absorptiometry and VO2max tests. Children were randomly allocated into a within-subjects crossover intervention design including 20-minutes of restful reading and 20-minutes of treadmill walking. Children completed post-intervention cognitive tasks that tap inhibition (Go-NoGo, flanker) with EEG (P3-ERP), and standardized tests of academic achievement in reading and math.

Summary of Results

Following the treadmill walking intervention, children of normal weight (NW) demonstrated improved response accuracy ($p \leq 0.05$), shorter reaction times ($p \leq 0.05$), and larger P3-ERP amplitudes ($p \leq 0.05$) during the Go task, relative to children with obesity (OB). Additionally, after the walking intervention, NW children demonstrated a trend for larger P3 amplitude ($p = 0.068$) during the NoGo task. NW children also demonstrated shorter reaction times ($p = .041$), and reduced perceptual interference ($p = 0.039$) compared to OB children during the flanker task. Lastly, NW children demonstrated improved performance on academic achievement tests of reading and math after the walking intervention, compared to OB children ($p \leq 0.05$).

Conclusion

These findings indicate that the beneficial effects following an acute bout of aerobic exercise on cognitive and brain function may be attenuated in children with obesity. These results provide evidence indicating that neuroelectric and behavioural indices of attention, inhibition, and academic achievement are influenced by aerobic exercise and body mass in children. Given that childhood obesity is a public health concern with an array of health complications, these results have important implications for the physical and cognitive health of children.

Effect Of Mental Fatigue Induced By A Cognitive Task On A Subsequent Handgrip Endurance Exercise
 Michel Francis Audiffren, Thomas Mangin, Nathalie André, Abdel Benraiss, Benjamin Pageaux. *University of Poitiers, Poitiers, France.* (Sponsor: Phillip TOMPOROWSKI, FACSM)
 Email: michel.audiffren@univ-poitiers.fr
 (No relevant relationships reported)

Mental fatigue is commonly observed when using the sequential task protocol. In this protocol, participants perform a first task that requires effortful control or that does not. Then, they have to perform a second task that systematically requires effortful control. Participants generally give up earlier the second task when they have exerted effortful control in the first task. Despite an extensive literature on this phenomenon, researchers still debate about its real existence and failed to define its conditions of occurrence.

PURPOSE: To replicate the mental fatigue effect with a long cognitive task tapping executive functions on a subsequent effortful physical task. **METHODS:** Fifty-five young adults completed 4 sessions separated by a minimum of 48h. The first session was a learning session in which participants familiarize with the Stroop task and the handgrip task. During the second session, participants only performed the endurance handgrip task at 13% voluntary maximal contraction until exhaustion. During the third and fourth sessions, participants performed a 30-min cognitive task (modified Stroop task vs. Video task) followed by the same handgrip task than in the 2nd session. The order of sessions 2 and 3 were counterbalanced across participants. **RESULTS:** As expected, participants squeezed the handgrip during a shorter time (5.36 min) after the Stroop task than after watching an emotionally neutral movie (5.82 min). In addition, there was a significant difference between the performance of the second session (5.80 min) and the performance after the Stroop task. **CONCLUSION:** This study clearly shows that a long task overloading execution functions leads to an early disengagement of mental effort in a subsequent effortful physical task. The cause of this earlier dropout is explained in different ways: (1) a quicker depletion of brain resources, (2) energetic and computational costs higher than the benefits associated with the achievement of the task goal, or (3) a reorientation of attention and intention to more pleasant tasks. Further studies are needed to confront these different explanations and manipulate the difficulty of the first task (duration and effortful control load) to determine the conditions of occurrence necessary to induce mental fatigue.

Effect Of Intermittent Isometric Handgrip Exercise On Cognitive Function
 Shotaro Saito¹, Kazuki Tamiya¹, Takuro Washio¹, Hironori Watanabe¹, Soichi Ando², Shigehiko Ogoh, FACSM¹. ¹Toyo University, Kawagoe, Japan. ²The University of Electro-Communications, Chofu, Japan.
 Email: shou0323279@gmail.com
 (No relevant relationships reported)

Previous study reported that an isometric handgrip (IHG) exercise improves cognitive function. However, an isometric exercise may increase the risk for cardiovascular disease because of a larger increase in arterial blood pressure (ABP) compare with dynamic exercise, especially in elderly patients. **PURPOSE:** The purpose of the present study was to examine the effect of acute intermittent IHG exercise without a large

increase ABP on cognitive function. **METHODS:** Five healthy subjects performed a cognitive task (Go/No-go task) before and immediately after IHG exercise protocols; 16 sets of 30-s IHG at 30% of maximum voluntary contraction and 45-s recovery. ABP was measured continuously throughout the experiment. Cognitive function was evaluated by the Go/No-go task. **RESULTS:** Mean arterial pressure at the end of IHG exercise protocol (92 ± 12 mmHg) was not significantly different from the baseline (86 ± 4 mmHg, $P > 0.05$). Also, the number of error trials in the Go/No-go task was unchanged; however, the reaction time was decreased in four out of five subjects after IHG exercise. **CONCLUSION:** These results provided the possibility that intermittent isometric exercise may improve cognitive function without an elevation in ABP. However, further investigation with large sample size is needed to identify our questions.

Relationship Between Aging-related Declines In Leg Muscle Volume And Quality And Cognitive Functions

Kento Dora¹, Takeshi Sugimoto¹, Okubo Sahomi¹, Keigo Katayama¹, Akifumi Maeda¹, Hayato Tsukamoto², Takuma Arimitsu¹, Naokazu Miyamoto³, Takeshi Hashimoto, FACS¹.
¹Ritsumeikan University, Kusatsu, Japan. ²University of South Wales, Pontypridd, United Kingdom. ³Juntendo University, Inzai, Japan. (Sponsor: Takeshi Hashimoto, FACS¹)
 (No relevant relationships reported)

PURPOSE: Aging is associated with declining in not only skeletal muscular function but also cognitive function including speed of processing, working memory, and long-term memory. However, it remains unclear whether aging-related decline in muscular function is related to impaired cognitive function. In addition to decreased muscle volume, aging-related decline in muscular function can be attributed to impaired muscle quality such as increased intramuscular fat and connective tissue (Akima et al, 2018; Goodpaster et al, 2006). The aim of the present study was to examine whether the aging-related declines in lower body muscle volume and quality are associated with cognitive function in Japanese adults. **METHODS:** The participants in this study were 86 adults (43 males, 43 females; age range 30 to 77 years old). The participants' thigh muscle volume was assessed by bioelectrical impedance analysis. Muscle quality (i.e., levels of intra- and extra-myocellular lipid and connective tissue) of the vastus lateralis was determined using 1H-magnetic resonance spectroscopy at 3T MR system and echo intensity measured with ultrasound. Cognitive functions (inhibitory control, short memory, working memory) were determined with the color-word Stroop task, Face-name matching task and Reading Span Test, respectively. **RESULTS:** Aging was associated with a decline in muscle volume and an increase in echo intensity ($p < 0.05$). The aging-related decline in muscle volume was correlated to impaired inhibitory control score in both male and female ($p < 0.05$). In addition, aging-related increase in echo intensity was correlated to impaired inhibitory control score ($p < 0.05$). There were no relationships between those muscle properties and short memory score or working memory score.

CONCLUSIONS: These findings suggest a link between aging-related impairment in inhibitory control and reduction in muscle volume and quality. Further studies are needed to determine whether ameliorating muscular function can be a therapeutic target against the aging-related decline in cognitive function.

Effectiveness Of Modeling Videos On Psychological States Of Patients Undergoing Rehabilitation Following ACL Reconstruction

Seo Jun Lee¹, Hye Chang Rhim¹, Jin Sung Jeon¹, Geun Kim¹, Kwang Yeol Lee¹, Ki-Mo Jang². ¹Korea University College of Medicine, Seoul, Korea, Republic of. ²Korea University Anam Hospital, Seoul, Korea, Republic of.
 Email: lsjohn236@gmail.com
 (No relevant relationships reported)

To date, much of the rehabilitation following anterior cruciate ligament reconstruction (ACLR) has centered on physical components. However, return to sports depends on not only physical recovery but also psychological readiness. According to a systematic review published in 2017, there is limited evidence on the efficacy of psychological interventions. **PURPOSE:** To examine the effectiveness of modeling videos to reduce preoperative kinesiophobia and fear of reinjury as well as to increase postoperative self-efficacy after ACLR. **METHODS:** Following baseline assessment of psychological states through ACL-Return to Sport after Injury (ACL-RSI), Knee Self Efficacy Scale (K-SES), and Tampa Scale of Kinesiophobia (TSK) and knee function (International Knee Documentation Committee [IKDC] system), patients scheduled for ACLR were randomly assigned to intervention, placebo, or control group. Six modeling intervention videos were developed by the investigators to represent six different periods: pre-operation, during hospitalization, 2 weeks, 6 weeks, 3 months, and 6 months post operations. Another six videos were developed to serve as placebo. Intervention and placebo groups watched their respective videos during

their follow-up visits while control group did not. All groups completed psychological and functional assessments during their follow-up visits. **RESULTS:** Ten patients were assigned to intervention group, 11 to placebo group, and 11 to control group. No significant changes in ACL-RSI, K-SES, and TSK scores over six-month period were found among groups ($p=0.574$, $p=0.808$, $p=0.888$, respectively). Although three groups all showed improvement in ACL-RSI, K-SES, and TSK at six months, their improvements were not linear ($p=0.467$, 0.364 , 0.274 , respectively). All groups demonstrated temporary decrease in ACL-RSI and TSK scores at three months. **CONCLUSIONS:** Watching modeling videos compared to placebo and control did not reduce kinesiophobia or fear of reinjury as well as improve self-efficacy after ACLR. However, there may be potential room for psychological intervention at three months, and it is important to recognize psychological readiness for successful return to sports.

Semantic Memory Activation After Training Cessation In Master Athletes

Junyeon Won¹, Lauren R. Weiss¹, Alfonso J. Alfini², James M. Hagberg¹, J. Carson Smith, FACS¹. ¹University of Maryland, College Park, MD. ²John's Hopkins University, Baltimore, MD.
 (Sponsor: J. Carson Smith, FACS¹)
 Email: andrewon1990@gmail.com
 (No relevant relationships reported)

PURPOSE: Despite a robust body of literature demonstrating the salutary effects of exercise on memory, we have yet to learn the link between exercise training cessation and memory in the aging brain. The aim of this study was to examine the effects of 10-day training cessation on semantic memory-related functional activation using task-activated functional magnetic resonance imaging (fMRI) in master athletes.

METHODS: Twelve master athletes (62.6±7.0 years) with long-term endurance training histories (≥15 years), were recruited from Washington DC area running clubs. Participants were instructed to remain sedentary and perform only activities of daily living for 10 days. Before and immediately after the training cessation period, fMRI semantic memory activation was measured during performance of a Famous and Non-Famous name discrimination task.

RESULTS: There were no significant differences in behavioral performance including response time and accuracy between pre- and post-training cessation. The 10-day training cessation was associated with greater semantic memory activation (Famous > Non-Famous) in five out of ten semantic memory-related regions (voxel-wise $p < 0.001$, FWE $p < 0.05$).

CONCLUSIONS: The present results provide evidence that even a relatively short period of exercise training cessation results in changes in semantic memory network function and suggests reduced neural efficiency during memory retrieval. This study also indirectly indicates potentially detrimental effects of sedentary behavior in older adults and highlights the importance of sustained participation in exercise.

Transient Effects Of Acute Aerobic Physical Activity On The Pupillary Response And Inhibitory Control

Tatsuya T. Shigeta, Donovan A. Henry, Peter Bex, Charles H. Hillman. Northeastern University, Boston, MA.
 Email: shigeta.t@husky.neu.edu
 (No relevant relationships reported)

Purpose: Acute bouts of aerobic exercise have been found to transiently improve executive function and its neural underpinnings. Moderate activation of the locus coeruleus-norepinephrine (LC-NE) system increases attention toward goal-directed behaviors, yet non-optimal activation may promote distractibility. Pupillary responses are believed to be a marker of the LC-NE system, and tasks requiring greater amounts of inhibitory control modulate baseline (tonic) and task-evoked (phasic) pupil dilation. The purpose of this study was to examine the pupillary response as a LC-NE biomarker to understand the mechanisms underlying the effect of acute exercise on inhibitory control.

Methods: Twenty-six participants (19.7 ± 1.8 yr, 17 female) performed 20 min interventions (seated rest/moderate intensity exercise) followed by Simon and modified flanker tasks. Participants' eyes were tracked during the tasks using a tabletop eye imaging camera at a 500hz sampling rate.

Results: RM-ANOVAs assessed intervention and inhibitory control (congruency/compatibility) effects on behavior and pupillary outcomes. Incongruent flanker trials resulted in longer reaction times and lower response accuracy, p 's ≤ 0.001. While incompatible Simon trials also resulted in longer reaction times, $p = 0.01$, there was no difference in response accuracy across compatibility conditions, $p = 0.11$. Peak phasic pupil dilation was also greater in incongruent flanker trials as well as incompatible Simon trials, $p=0.003$. While behavior and phasic pupil dilation in both tasks did not

differ across the exercise vs. rest interventions, p 's ≥ 0.18 . Tonic pupil diameter was larger for the exercise intervention in the flanker task, $p = 0.04$, and at trend level in the Simon task, $p = 0.09$.

Conclusion: The tonic pupillary response may be a sensitive biomarker for examining transient changes in LC-NE activity as a function of acute exercise bouts. Moderate intensity exercise did not significantly affect phasic pupillary response. These findings indicate that the pupillary response can be manipulated by aspects of inhibitory control and physical activity, which suggests it may be a sensitive biomarker for examining changes in LC-NE activity.

Perception Of Trust In Physicians Based On Somatotype: A Student And Non-student Comparison
 Danielle Hemingson, Felicia Raybourn. *Baker University, Baldwin City, KS.* (Sponsor: Justin Kraft, FACSM)
 (No relevant relationships reported)

Appearance is the first piece of information available that can powerfully influence perception. Credibility, which includes trust, has been shown to be impacted by a person's somatotype. **PURPOSE:** The purpose of this study was to determine students and non-students perception of trust of a physician based on the physician's somatotype. **METHODS:** A survey was administered to 1,631 students, faculty, and staff at a small Midwestern university using Formstack. Images of an endomorph, mesomorph, and ectomorph somatotype were displayed along with a 5-point Likert scale with 1 meaning "would not trust this physician" to 5 meaning "would completely trust this physician". Participants were asked to select the answer that best correlated with the perceived trust they would have in a physician who had the somatotype shown. **RESULTS:** There were 1,631 emails sent with 333 (20%) responses collected. Of the 333 respondents, 189 (57%) were students and 144 (43%) were non-students (faculty and staff). Perceptions of trust were analyzed using a repeated measure ANOVA which determined there is a significant difference in rank order of the three somatotypes (p -value $< .0001$). A Tukey post-hoc test was then conducted to compare the three somatotypes. When comparing the means for endomorph ($M = 2.7$, $SD = 1.1$) and mesomorph ($M = 3.8$, $SD = .7$), the endomorph somatotype was ranked lower than the mesomorph somatotype ($t = -19.756$, p -value $< .0001$). When comparing the means for the endomorph and ectomorph ($M = 3.6$, $SD = .9$) somatotypes, the endomorph somatotype was ranked lower than the ectomorph somatotype ($t = -15.583$, p -value $< .0001$). Lastly, when comparing the mesomorph and ectomorph somatotypes, the mesomorph somatotype ranked higher than ectomorph somatotype ($t = 4.173$, p -value $< .0001$). **CONCLUSION:** This study indicated that both status groups (students and non-students) ranked the mesomorph somatotype as most trustworthy for a physician, the ectomorph somatotype as second most trust worthy for a physician, and the endomorph somatotype as least trustworthy for a physician. Further research is needed to determine the influencing factors of somatotype perceptions.

2286 Board #205 May 28 2:00 PM - 3:30 PM
Primes For The Mind: Additive Effects Of Verbal Priming And Acute Exercise On Convergent Creativity
 Emily Frith, Stephanie E. Miller, Paul D. Loprinzi. *University of Mississippi, University, MS.* (Sponsor: Dr. Jeremy P. Loenneke, FACSM)
 (No relevant relationships reported)

PURPOSE: The Remote Associates Test (RAT), assesses creative convergence on a single solution. The effects of physical exercise on convergent creativity are equivocal; although, priming has been shown to improve convergent thinking. To this end, we hypothesized that acute, moderate-intensity treadmill-walking while solving anagram primes would stimulate additive effects capable of facilitating convergent creativity, relative to priming alone.

METHODS: Participants ($n=45$) completed two laboratory visits in this within-subject experiment. Six anagram lists were presented during each visit (twelve total lists), with the order of the twelve lists counterbalanced across conditions. Participants randomly assigned to the anagram priming + exercise visit first, performed fifteen minutes of moderate-intensity treadmill-walking (moderate-intensity; 40-45% of heart-rate reserve while solving anagrams). Participants, randomized into the anagram only visit first, sat on a stool placed on the treadmill for fifteen minutes while solving anagrams. Following fifteen minutes of exercise + anagram-solving or seated rest + anagram-solving, participants were escorted to a quiet room, free of distraction, where they solved RAT problems. After a minimum 24-hour interval, participants returned for the second visit. Paired t-tests were used to test differences between both conditions. Post-hoc Bayesian analysis was also performed to quantify evidence for or against the null hypothesis.

RESULTS: A significant difference was evident between exercise + anagram-solving ($= 10.51$, $SD = 3.25$) and seated rest + anagram-solving ($= 9.29$, $SD = 4.12$), $t(44) = 2.385$, $p = .021$, $d = 0.36$, 95% confidence interval for the effect size = 0.052 - 0.655).

Post-hoc Bayesian analysis indicated that the data were 2.05 times more likely under the alternative hypothesis (median $\delta = 0.46$, 95% credible interval for the effect size = 0.053 - 0.86).

CONCLUSION: This experiment offers a novel contribution to the exercise and creativity domains, suggesting a potential additive effect of exercise plus verbal priming on convergent creativity. Continued empirical research is warranted to identify precise mechanisms underlying these additive effects, and to establish novel exercise and priming strategies that may benefit creative thinking.

Parent-report Of Children's Motor Skills Are Selectively Related To Interference Control Among School-aged Children

Shelby Keye¹, Caitlyn G. Edwards¹, Corinne N. Cannavale¹, Samantha J. Iwinski¹, Ginger E. Reeser¹, Anne D.M. Walk², Emiliano Mazzoli³, Lisa M. Barnett³, Naiman A. Khan¹.

¹University of Illinois, Urbana-Champaign, IL. ²Eastern Illinois University, Urbana-Champaign, IL. ³Deakin University, Urbana-Champaign, IL. (Sponsor: Steven J. Petruzzello, FACSM)
 (No relevant relationships reported)

PURPOSE: Previous research has demonstrated that aerobic fitness and adiposity impact children's cognitive function. However, whether children's motor skills independently impact childhood cognition remains unclear. This study examined relationships between children's motor skills and executive function, relational memory, and academic achievement among school-aged children without diagnosed coordination disorder. **METHODS:** Participants were children ages 7-12 years old ($N=90$ [46 females]). Intellectual abilities and academic achievement were measured using the Woodcock-Johnson IV Test (WCJ). Selective attention was assessed using a Flanker task, and relational memory was assessed using a spatial reconstruction task. Aerobic fitness and whole-body adiposity (%Fat) were assessed using a VO2max test and DXA, respectively. Parents completed the Developmental Coordination Disorder Questionnaire (DCDQ) as an assessment of the child's current motor skill abilities. Spearman and partial spearman correlation tests were conducted to explore potential relationships. **RESULTS:** 14% of participants indicated a possible developmental coordination disorder and 50% had a score of 67 and above on the DCDQ. Covariates adjusted for included sex, IQ, socioeconomic status (SES), fitness, and %Fat. Following adjustment, higher scores on the control during movement subscale of the DCDQ were related to greater performance in story recall ($Rho = 0.29$; $P = 0.039$), a subscale of the WCJ. There was no significant relationship between relational memory and any of the DCDQ outcomes. However, higher scores on the control during movement subscale were related to lower accuracy interference during the Flanker task ($Rho = -0.25$; $P = 0.03$), indicating that children who had higher motor control while moving exhibited greater selective attention, compared to those who had poorer control abilities during movement. **CONCLUSION:** Motor control abilities were associated with recall memory and attentional abilities in school-aged children, independent of aerobic fitness and adiposity.

Influence Of Acute Resistance Training On Memory, Executive Function, And Mood

Patrick James Barney, 2nd, Cannon Greco Hiranaka, Daniela Spagnoli, Andrew Venezia. *University of Scranton, Scranton, PA.*
 Email: patrickbarney2468@gmail.com

(No relevant relationships reported)

Acute exercise has been shown to improve performance on several domains of cognitive function. The majority of research has focused on the benefits of aerobic exercise, but research on the cognitive and mood effects of acute heavy resistance training (RT) is limited. **PURPOSE:** To determine how an acute bout of RT affects cognitive function and mood. **METHODS:** This was a within subjects design. College-aged males ($n=21$) visited the laboratory on 3 days, separated by at least 1 week. During session 1, subjects were tested for their 5 repetition maximum (5RM) on the box squat, bench press, and lat pulldown. During sessions 2 and 3, participants completed a rest or RT condition in a counterbalanced order. Prior to both sessions, participants completed trials 1-6 of the Rey Auditory Verbal Learning Task (RAVLT). During the RT session, participants completed 3 sets of 8-12 repetitions at 70% of estimated 1RM on the box squat, bench press, and lat pulldown. Training took ~40 minutes (including warm-up and cool-down). After the RT or 40 min seated rest, participants completed the recall and recognition trials of the RAVLT and a cognitive test battery in the Automated Neuropsychological Assessment Metrics (ANAM) Test System. The test battery included 10 tests that assessed memory, processing speed, executive function, and mood. Comparisons in cognitive performance and mood were made using a paired t-test. **RESULTS:** Higher scores on the color subtest of the Stroop Task, a test of processing speed, were found after RT compared to rest

(training=69.57±2.03; rest=65.43±2.01; p=0.01). Better performance was observed in the Matching-to-Sample task, a spatial working memory task, after rest compared to RT (training=41.33±2.77; rest=45.33±2.53; p=0.03). There were no other differences in cognitive performance between conditions (p>0.05). After RT, participants had higher anger (training=11.05±3.34; rest=5.62±1.81; p=0.04), depression (training=6.43±2.22; rest=2.57±1.08; p=0.02), restlessness (training=32.33±4.15; rest=14.58±3.18; p=0.0001), and vigor (training=55.62±3.63; rest=48.24±3.90; p=0.04). **CONCLUSION:** Acute RT has limited effects on cognitive function in college-aged males, but increases anger, depression, restlessness, and vigor when assessed after cognitive tasks.

Psychological State Of A World-Class Ultramarathon Runner: A Case Study

Nicole D. Bolter¹, Jacob S. Dinardi¹, Ryan P. Durk¹, Gwenaelle Begue², Gregory J. Grosicki³, James R. Bagley¹. ¹San Francisco State University, San Francisco, CA. ²Sacramento State University, Sacramento, CA. ³Georgia Southern University (Armstrong Campus), Savannah, GA.

Email: nbolter@sfsu.edu

(No relevant relationships reported)

PURPOSE: While previous studies have revealed various physiological effects of ultramarathon running, the psychological profile and well-being of ultramarathon runners is less often examined and therefore inadequately understood. According to Self-Determination Theory (Ryan & Deci, 2000; 2002), an individual's well-being can be enhanced by participating in activities that support, not thwart, their basic needs of competence, autonomy, and relatedness. Psychological constructs of basic needs satisfaction, well-being, and mental toughness can be considered relatively stable. Yet, it is unknown whether these constructs vary before and after a highly intense exercise bout such as an ultramarathon. In previous studies, the timing of assessing endurance athletes varied from 5 minutes to 4 weeks post-event (Holt, Lee Kim, & Klein, 2014; Micklewright et al., 2009). This case study examined the pre- and post-race psychological profile of a male top-ten finisher of the Western States Endurance Run (WSER), a 100-mile (161 km) foot race over mountainous trails of Northern California in the United States. **METHODS:** The 32-year old participant was a highly-trained ultramarathon runner. At 20 hours prior to the race, the participant completed a quantitative survey about basic needs satisfaction, basic needs thwarting, self-esteem, mental toughness, and affect. When asked to complete the same survey 100 minutes post-race, the participant said he could not focus and asked to complete the survey later at 34 hours post-race. **RESULTS:** Results revealed an adaptive psychological profile that was stable from pre- to post-race; very high scores on basic needs satisfaction ($M_{pre} = 6.9$, $M_{post} = 6.85$ on a 7-point scale), self-esteem ($M_{pre} = 4.0$, $M_{post} = 4.0$ on a 4-point scale), mental toughness ($M_{pre} = 6.5$, $M_{post} = 6.63$ on a 7-point scale), and positive affect ($M_{pre} = 4.9$, $M_{post} = 5.0$ on a 5-point scale), combined with very low scores on basic needs thwarting ($M_{pre} = 1.0$, $M_{post} = 1.0$ on a 7-point scale) and negative affect ($M_{pre} = 1.2$, $M_{post} = 1.2$ on a 5-point scale). **CONCLUSIONS:** While survey results indicated stability in the athlete's psychological state, future research should explore the optimal post-event window to assess psychological constructs of ultra-marathon runners as well as other endurance athletes.

Long-term Exercise Training Prevents Anxious-depressive-like Behavior In Transgenic Alzheimer Rats

Luodan Yang¹, Chongyun Wu², Yong Li¹, Yan Dong¹, Lorelei Donovan Tucker¹, Baocheng Yang¹, Xuemei Zong¹, Quanguang Zhang¹. ¹Augusta University, Augusta, GA. ²South China Normal University, Guangzhou, China.

(No relevant relationships reported)

PURPOSE: This study examined the effects of long-term treadmill exercise training on the anxious-depressive-like behavioral phenotype of transgenic Alzheimer rats in the early stage of Alzheimer's disease (AD) development and provided evidence that exercise alleviated fear-avoidance behavior deficits. **METHODS:** 2-month-old Male TgF344-AD and wild-type (WT) rats were separated into WT (n = 9), AD (n = 8), and AD + treadmill exercise (Exe) groups (n = 12). Following 8 months of exercise, the passive avoidance test, Barnes maze task, novel object recognition test, and object location test were used to measure learning and memory function. The open field test, elevated plus maze, sucrose preference test, and forced swim test were conducted to measure anxious-depressive-like behavior of AD rats. Immunofluorescence staining, Western blot analysis, enzyme-linked immunosorbent assay (ELISA) analysis, and related assay kits were used to measure levels of inflammatory cytokines, oxidative stress, amyloid-beta production, and tau hyperphosphorylation. **RESULTS:** Behavioral tests indicated that AD rats aged 12-months did not exhibit spatial learning and memory deficits, but did display anxious-depressive-like behaviors (open field, Center time: $P = 0.008$; Center entries: $P = 0.009$; Line crossings: $P = 0.001$). Long-term exercise significantly prevented anxious-depressive-like behaviors in AD rats (Center

time: $P = 0.016$; Center entries: $P = 0.004$; Line crossings: $P = 0.033$). In addition, AD animals displayed enhanced A β deposition ($P < 0.001$), Tau hyperphosphorylation ($P < 0.001$), microglial activation ($P < 0.001$), inflammatory cytokine release ($P < 0.05$), and oxidative damage ($P < 0.05$) that was attenuated significantly after long-term exercise training ($P < 0.05$). **CONCLUSIONS:** Long-term exercise training ameliorated anxious-depressive-like behaviors and improved fear-avoidance behavior in transgenic AD rats, supporting exercise training as an effective strategy to prevent or reduce anxiety, depression and fear-avoidance behavior deficits in the early stages of AD pathogenesis.

The Effect Of Treadmill Desk Walking On Creative Thinking

Rebecca R. Rogers, Daphne Schmid, Christopher G. Ballmann. *Samford University, Birmingham, AL.*

(No relevant relationships reported)

PURPOSE: Most research on treadmill desks in the workplace report no significant change in productivity. However, most of these studies focused on cognitive performance measured by tests in attention, memory or reasoning. While aerobic exercise has been linked to producing a positive effect on creative potential, few studies have tested workplace creativity thinking. The purpose of this study was to examine the effect of treadmill desk walking on convergent and divergent creative thinking.

METHODS: Twelve (n=12) male and female college-age students were recruited and completed three tests of creative function: the verbal Guilford's Alternate Uses Task (VGAT) of divergent thinking, written Guilford's Alternative Uses Task (WGAT), and the Remote Associations Task (RAT) of convergent thinking. Participants completed all tests while seated at a traditional desk and while walking on a treadmill desk at 1.5 mph. Step length, stride length, and gait cycle were assessed by the OptoGait gait analysis system. A paired sample t-test was used to compare creative test scores and gait variables.

RESULTS: There were no significant differences between any test scores while seated and walking (p>0.05). There was no significant difference between baseline gait and divergent thinking (VGAT, WGAT) task gait in any variable (p>0.05). There was a significant increase in step length (p=0.049), stride length (p=0.046), and gait cycle (p=0.039) between the walking only condition and the treadmill desk walking during the RAT. **CONCLUSIONS:** Results of this study suggest neither convergent nor divergent creative thinking are improved when walking on a treadmill desk. While gait patterns are not changed during divergent thinking, this study suggests gait during convergent thinking may be altered.

Acute But Not Chronic Aerobic Exercise Enhances Attention And The Neuroelectric Mismatch Negativity Among Fatigued Individuals

Mitchel B. McRay¹, Tim Puetz², Patrick J. O'Connor, FACSM³, Rodney K. Dishman, FACSM³, Brett Clementz³, Nate Thom¹. ¹Wheaton College, Wheaton, IL. ²Department of Veterans Affairs, Washington D.C., DC. ³University of Georgia, Athens, GA.

Email: mitchel.mcray@my.wheaton.edu

(No relevant relationships reported)

PURPOSE: Symptoms of fatigue are a public health burden, comorbid with both cardiovascular disease and cancer. While exercise requires considerable energy expenditure, both acute and chronic aerobic exercise reduce feelings of fatigue. However, the brain mechanisms underlying this effect are not well-understood. To explore the neural mechanisms of this effect, we examined EEG correlates of attention before and after acute and chronic aerobic exercise. We hypothesized that the lo-intensity acute and chronic effects of exercise would produce increased attentiveness. **METHODS:** In this pilot study, 13 students, ages 18-36, with elevated levels of fatigue, were randomly assigned to: lo-intensity, hi-intensity, and a no exercise control. Each participant was evaluated pre- and post-exercise three times (e.g., baseline, week 3, and post-intervention) during the 6-week study. At each session participants were outfitted with hi-density EEG and completed an auditory odd-ball task that resulted in a mismatch negativity (MMN). The MMN is an index of pre-attentive change detection, and its amplitude decreases with fatigue. EEG was analyzed via established guidelines including ICA algorithms for artifact-removal. To extract the MMN, the N1 was located in each recording and a difference wave was calculated by subtracting the electrocortical activity to the standards minus targets, in the 100ms after the N1 (120-220ms). **RESULTS:** A repeated-measures, mixed model ANOVA (3 Group (lo-intensity, hi-intensity, control) x 2 Time (pre/post intervention) x 3 Week (baseline, week 3, post-intervention)) revealed a marginally significant interaction between Group, Time, and Week [$F(4,16)=2.79$, $p=0.06$, $\eta^2=0.41$] such that the MMN was reduced after hi-intensity exercise at the final session. In addition, the 2-way interaction between Group and Time [$F(2,8)=4.05$, $p=0.06$, $\eta^2=0.50$]

revealed a marginally significant interaction such that the lo-intensity group showed an increased MMN amplitude post exercise, the hi-intensity group showed a decrease, and the control group showed no change. No other effects were significant (all $p > 0.24$, $\eta^2 < 0.29$). **DISCUSSION:** Our data suggest that automatic pre-attentive change detection is only altered after lo-intensity acute aerobic exercise among our sample of fatigued individuals.

Fitness Related Differences And Neuroelectric Indices Of Arithmetic Approximation In College-aged Adults
 Oksana Ellison, Morgan S. Ham, Madison C. Chandler, Matthew B. Pontifex, Amanda L. McGowan. *Michigan State University, E. Lansing, MI.*
(No relevant relationships reported)

As a growing body of literature supports a positive association between aerobic fitness and mathematics achievement, it has been suggested that individuals higher in aerobic fitness may use strategies, such as arithmetic approximation, that are more efficient during mathematical reasoning. **Purpose:** To understand how individuals at extremes of the aerobic fitness spectrum differ on numerical approximation. **Methods:** A sample of higher- and lower-fit college-aged adults was recruited to participate in the study based on maximal oxygen consumption ($\dot{V}O_{2max}$). Participants performed a complex arithmetic approximation task presenting operands $a + b$ and were instructed to indicate whether the sums were greater than or less than 100. Problems were equally distributed across conditions that varied in the extent to which the operands required arithmetic approximation: extra small split (i.e., $\pm 2\%$ or 3% ; $63+39$, medium split (i.e., $\pm 5\%$ or 8% ; $69+26$), large split (i.e., $\pm 10\%$ or 15% ; $48+62$), and massive split (i.e., $\pm 50\%$ or 55% ; $64+86$). To determine the extent to which arithmetic strategy differed between fitness groups, behavioral and neural indices of cognitive processing were assessed. **Results:** Numerical conditions requiring relatively lower levels of arithmetic approximation were not observed to differ between higher-and lower-fit participants whereas the numerical conditions requiring arithmetic approximation exhibited fitness-related differences. **Conclusion:** These findings suggest that high-fit individuals may engage in more efficient mathematical reasoning strategies relative to their low-fit counterparts. Therefore, fitness-related differences in mathematics achievement may result from differences in strategy execution. Future research should examine the degree to which physical activity interventions designed to enhance aerobic fitness also result in shifts in arithmetic approximation strategy.

Pre-Competition Emotions In Cheerleading Sport: Differences Across Gender And Association With Final Results
 claudia Dias Leite¹, Ana Carolina V. Moraes², Filipe M L Rezende², Róbson C. Silva², Isabela A. Ramos¹. *Universidade Católica de Brasília and Centro Universitário UniProjeção, Brasília, Brazil.* ²Centro Universitário UniProjeção, Brasília, Brazil.
 Email: ahbeuramos@gmail.com
(No relevant relationships reported)

Although cheerleading's history is long until relatively recently it was not considered a sport. The evaluation is based on an assessment of strength, flexibility, and perfection of routine. Despite positive energy, charisma, and joy, during a competition, athletes can experience positive and negative emotions that could influence performance. **PURPOSE:** to analyze pre-competition emotions in a final cheerleading university games participation, assessing differences between male and female cheerleaders and associating positive and negative emotions with the score obtained in the competition. **METHODS:** From six universities 40 cheerleaders (n=22 male; n=18 female), mean age was 21.03 yr (SD 1.51), participated in the study, they competing at the National University Games in Bahia, Brazil. The teams were finalists in the first time of cheerleading participation in 67 editions of this competition. The twenty-two items of the Pre-Competitive Emotion Scale in the Portuguese language were selected from the original scale developed earlier (Jones et al., 2005). This scale has positive (e.g., happy, excited, enthusiastic) and negative (e.g., angry, sad, tense) emotions. Athletes were asked to rate how intense they were experiencing the emotions through self-evaluation 30min before the competition, on a scale in Likert format anchored by 1 (not at all) to 5 (very much so). **RESULTS:** Cheerleaders athletes experienced positive emotions (3.82 ± 0.69) more intensely than negative emotions (1.94 ± 0.44). In gender comparison, the independent sample t-test showed a significant difference in negative emotions (m. 1.78 ± 0.36 vs f. 2.14 ± 0.46 ; $p=0.009$) and a non-significant difference in positive emotions (m. 3.91 ± 0.64 vs f. 3.72 ± 0.76 ; $p=0.42$). Pearson correlation also indicated a significant, weak, positive correlation ($r=0.35$; $p=0.02$) between positive emotions and final score, while the negative emotions demonstrated a non-significant correlation ($r=-0.03$; $p=0.81$). **CONCLUSIONS:** Cheerleaders experienced both, positive and negative pre-competitive emotions. As well, female athletes experienced

more intense negative emotions than male athletes, and the intensity of positive emotions was related to the final score. This information may be useful for training psychological aspects and emotional control.

2295 Board #214 May 28 2:00 PM - 3:30 PM
The Mechanism Of Dance Training Regulating Emotion Of College Students: A FMRI Study
 Rou Wen¹, Lijuan Hou², Jilong Shi², Jingjing Xue¹, Mi Zhang². *¹Beijing Dance Academy, Beijing, China. ²Beijing Normal University, Beijing, China.*
(No relevant relationships reported)

PURPOSE: The purpose of the study is to evaluate the effect of dance training on emotion regulation of college students and explore the possible mechanism by using a magnetic resonance imaging (MRI) technique.

METHODS: 30 healthy college students were selected, 15 majored in classical Chinese dance (Dance Training group, DTG) and 15 (Control Group, CG) have no previously experience of regular training. MRI technique was used to observe the effect of dance training on the structure and function of emotion related brain areas. Siemens MAGNETOM Trio 3.0t MRI was selected and data analyzed by ALFF/FC with GREYNA.

RESULTS: Compared with CG, whole brain (1366 ± 88 ml), gray matter (674 ± 49 ml), white matter (488 ± 39 ml) was no significant difference with DTG ($P > 0.05$). The structural of left BA20 of DTG was increased significantly (voxels=142, $t=5.91$). The structural of left anterior cingulate gyrus, right central cingulate gyrus and insula gray matter decreased significantly in DTG ($P < 0.05$). With the increase of training years, the structural volume of BA20 gray matter increased significantly (voxels=420, $r=0.80$). In DTG the ALFF value and ReHo value in BA48 and BA23 were significantly increased ($P < 0.05$). The functional connections between the left insula and the right transverse temporal gyrus and the left superior temporal gyrus were enhanced ($P < 0.05$). Also right insula and the left amygdala, transverse temporal gyrus, superior temporal gyrus, middle temporal gyrus, inferior temporal gyrus and transverse temporal gyrus were significantly enhanced ($P < 0.05$).

CONCLUSIONS: The possible mechanism of dance training regulating emotion of college students may be relevant to the changes of structure, function and functional connections of emotion related brain areas. The effect of dance training on emotion regulation is highly related to the years of dance training (Supported by The Innovation ability promotion Plan Foundation of Beijing Municipal Education Commission No.TJSH20161005101).

Cognitive Response And Motor Speed Before And After A Sustained Endurance Run
 Patrick M. Davitt, FACSM. *University of the Sciences, Philadelphia, PA.*
 Email: pdavitt@uscience.edu
(No relevant relationships reported)

There has been some controversy regarding the effects of physically exhausting the human body through endurance exercise. When it comes to the fatigue of the muscular system and being "physically tired", there is a question of the mental fatigue that such sustained physical exercise can take on the body.

PURPOSE: To test the differences in quick thinking tasks and reaction time before and after a 3-hour treadmill run, in trained endurance males.

METHODS: 10 male endurance runners (32 ± 6.0 yr; 161.3 ± 20.7 lb, 68 ± 1.6 in; $14.7 \pm 6.6\%$ body fat) ran for 3-hours on the treadmill (6.1 ± 0.2 mph, $57 \pm 0.9\%$ $\dot{V}O_{2max}$) for 18.3 ± 0.6 miles, on 3 separate occasions and performed a STROOP interference test, Reaction time test, and a 30 second finger-tapping test pre-run (PRE) and immediately after the treadmill run (POST).

RESULTS: There was a significant improvement in the cumulative time it took for successful responses in the STROOP test POST vs. PRE (24.36 ± 0.68 ; 28.44 ± 1.09 sec; $p < 0.05$). There was a significantly slower average response time when responding to different word colors, vs. the same color for the word ($p < 0.05$). There was a significant improvement in reaction time POST vs. PRE (0.44 ± 0.004 ; 0.48 ± 0.006 sec; $p < 0.05$). There was no significant difference between PRE and POST 3-hr run finger tapping score (209.1 ± 4.6 ; 211.1 ± 4.7 taps; $p=0.45$).

CONCLUSIONS: These results provide support to indicate that even after a fatiguing 3-hr treadmill run, at a moderate intensity, mental response time to cognitive tasks and the reaction time of trained, male endurance runners is not diminished, and is even significantly improved.

2297 Board #216 May 28 2:00 PM - 3:30 PM
The Effect Of Behavioral Automaticity On Behavior Is Moderated By Cognitive Self-control Abilities
 Ines Pfeffer, Tilo Strobach. *Medical School Hamburg, Hamburg, Germany.*
Email: ines.pfeffer@medicalschoo-hamburg.de
 (No relevant relationships reported)

PURPOSE: Dual-process theories assume that physical activity (PA) behavior is regulated by two different processes: *implicit* (i.e., automatic, unconscious) and *explicit* (i.e., effortful, conscious) processes. In this study we examined the interaction of implicit (i.e., behavioral *automaticity*) and explicit (i.e., cognitive self-control abilities) processes on PA behavior. We expected significant interaction effects between behavioral automaticity and cognitive self-control abilities (i.e., inhibition): highly automatized behaviors will prevail when inhibition abilities are poor, while high inhibition abilities might help to inhibit unwanted automatic behavioral tendencies (e.g., highly automatized sedentary behaviors [SB]).

METHODS: A prospective study with two points of measurement ($N = 114$ undergraduate and graduate students) was conducted. At t1 age, sex, past PA behavior (control variables) and *automaticity* of a) PA and b) SB were assessed with standardized questionnaires. Inhibition was assessed with a computerized Stop-Signal and a Go/No-Go task. At t2 (4 weeks later), PA behavior was measured as dependent variable with a standardized questionnaire. Hierarchical multiple linear regression analyses with interactions *Automaticity* x *Inhibition* on PA behavior and subsequent moderation analyses were calculated for *automaticity* of a) PA and b) SB respectively. **RESULTS:** The expected interaction effects *Automaticity* x *Inhibition* on PA behavior were significant for *automaticity* of a) PA ($b = 55.23, p < .01$) as well as b) SB ($b = -27.40, p < .05$). Moderation analyses revealed that *PA automaticity* was a significant positive predictor of PA behavior when inhibition abilities were poor ($b = 105.75, SE = 23.13, t = 4.57, p < .001$), but not when they were high ($b = -11.10, SE = 24.71, t = -0.45, p = .65$). Furthermore, *automaticity* of SB was a significant negative predictor of PA behavior when inhibition abilities were poor ($b = -42.83, SE = 20.87, t = -2.05, p < .05$), but not when they were high ($b = 13.67, SE = 17.61, t = 0.77, p = .44$).

CONCLUSIONS: In line with theoretical assumptions, automatic behaviors prevailed when the ability to inhibit prepotent responses was poor. However, higher inhibition abilities erase the significant associations between automaticity and behavior for both, PA and SB automaticity.

Preschoolers' Self-regulation, Fine Motor Skills, And Performance On A Standardized Literacy Assessment
 Madison C. Chandler¹, Kyla Z. McRoy¹, Sarah Goodwin¹, Ryan P. Bowles¹, Gary E. Bingham², Hope K. Gerde¹, Matthew B. Pontifex¹. ¹*Michigan State University, East Lansing, MI.*
²*Georgia State University, Atlanta, GA.*
Email: chand138@msu.edu
 (No relevant relationships reported)

In early childhood, both self-regulation and fine motor skill proficiency are positively related to academic achievement – and recent research suggests that these two factors are interrelated and co-develop such that skill in one may make up for deficiencies in another. **PURPOSE:** The aim of the present investigation was to determine the extent to which fine motor skill moderates the relationship between self-regulation and performance on a standardized literacy assessment in a sample of preschoolers. **METHODS:** Three hundred forty children from Head Start programs in Michigan and Georgia ($M_{age} = 3.76$ years; 172 females; 64% African-American) completed assessments of self-regulation (the Head-Toes-Knees-Shoulders task; McClelland et al., 2014), fine motor skills (the Early Skills Inventory – Revised; Meisels et al., 1997), and emergent literacy skills (the Test of Preschool Early Literacy; Lonigan et al., 2007). Hierarchical regression analyses were conducted to examine the potential moderating association between fine motor skill and self-regulation on emergent literacy skills. **RESULTS:** Replicating extant literature, self-regulation was a statistically significant predictor of emergent literacy skills, $\beta = 0.51, R^2_{adj} = 0.26, p < 0.001$. Novel to the current investigation, fine motor skills were found to moderate this relationship ($\beta_{self-regulation} = 0.53, \beta_{fine\ motor\ skills} = 0.42, \beta_{interaction} = -0.22; R^2_{change} = 0.10; p \leq 0.03$) such that higher fine motor skills were associated with enhanced emergent literacy skills in children with lower levels of self-regulation, but the impact of fine motor skills was attenuated for children with higher levels of self-regulation. **CONCLUSION:** These findings suggest that physical activity interventions designed to enhance fine motor skills could be beneficial in populations with low self-regulatory abilities, given the compensatory relationship between self-regulation and fine motor skills.

2299 Board #218 May 28 2:00 PM - 3:30 PM
Association Of Physical Health And Exercise Intervention With Stress, Depression And Life Satisfaction Among Chinese College Students
 Zhonghui HE, Di Lu. *Department of Physical Education, Beijing, China.*
Email: hezhongh@pku.edu.cn
 (No relevant relationships reported)

PURPOSE: This study explores the relationship between Chinese college Students' different levels of physical health and their perceived stress, depression and life satisfaction, then to analyze the impact of university exercise intervention courses on the above-mentioned mental health. **METHODS:** The sample consisted of 991 college students (Males: $N=371$, Age: $M=19.07$ years old) who were voluntarily enrolled in a 10-week weekly exercise intervention course in a famous university of china fitness courses, personal net-separating courses, collective antagonism courses. Before exercise intervention, they uniformly scored physique tests according to the requirements of the National Standards for Physical Health of Students. Perceived Stress Scale (Sheldon Cohen, 1994), Center for Epidemiological Studies Depression (Hann, Winter & Jacobsen, 1999) and Life Satisfaction Scale (Dew & Huebner, 1994) were filled in before and after exercise intervention. **RESULTS:** The better the physical health of College students, the higher their life satisfaction ($R=-0.121, P<.01$), and the lower their perceived stress ($R=-0.085, P<.01$) and depression level ($R=-0.052, P<.05$). Significant decreases were observed for depression in genders, grades and sports courses ($T=12.056, P<.01$). The students whose physical health level are "excellent" ($F=-3.421, P<.05$), "good" ($F=-1.728, P<.01$) and "pass" ($F=-1.003, P<.05$) have lower perceived stress level than the students whose physical health level is "failed". And whose physical health level are "excellent" ($F=4.598, P<.01$), "good" ($F=2.592, P<.01$) and "pass" ($F=1.859, P<.01$) have better life satisfaction than those whose physical health level is "failed". **CONCLUSIONS:** Students with better physical health have significantly higher life satisfaction, lower perceived stress and depression. Physical education course plays an active role in regulating the perceived depression of College students.

2300 Board #219 May 28 2:00 PM - 3:30 PM
Coping Skills Of Wildland Firefighters
 L. Donovan Robinson, Michael C. Meyers, FACSM, Shad K. Robinson. *Idaho State University, Pocatello, ID.*
 (No relevant relationships reported)

Nearly 14,000 firefighters are employed to combat wildland fires resulting in 13 fatalities and 270 injuries per year. Their ability to cope during stressful situations is critical for optimal performance to prevent morbidity and mortality. **PURPOSE:** To quantify the coping skills of wildland firefighters. **METHODS:** Following written informed consent, a modified Athletic Coping Skills Inventory (ACSI): coping with adversity (COPE), peaking under pressure (PEAK), goal setting/mental preparation (GOAL), concentration (CONC), freedom from worry (FREE), confidence and achievement motivation (CONF), coachability (COACH), and personal coping resources (PCR) and a modified Sports Inventory for Pain (SIP): direct coping (COP), cognitive (COG), catastrophizing (CAT), avoidance (AVD), body awareness (BOD), and total coping response (TCR) were completed by 140 wildland firefighters (mean age = 28.5 ± 13.9 yrs). Data were grouped by occupation (hotshot, smokejumper), job description (supervisor, manager, worker), and years of experience (1-9, 10-19, 20+). Raw ACSI and SIP scores were converted to normalized standard scores (T-scores; mean = 50, SD = 10). **RESULTS:** MANOVAs (Wilks' λ criterion) had a significant main effect by job description ($F_{8,139} = 1.919, p = .019$) and years of experience, ($F_{8,139} = 1.835, p = .027$) but not occupation ($F_{8,139} = 1.53$). Post hoc analysis indicated that supervisors scored significantly higher on PEAK ($p = .028$) than managers and workers, respectively. Post hoc analysis indicated 20+ yrs of experience scored significantly higher on FREE ($p = .031$), while 10-19 yrs scored significantly higher on PEAK ($p = .045$). In terms of pain coping, MANOVA indicated a significant main effect by occupation ($F_{6,139} = 3.104, p = .011$). Post hoc analysis indicated that hotshots scored significantly higher on CAT ($p = .014$) AVD, ($p = .002$) but lower BOD ($p = .008$) than smokejumpers, respectively. No other significant main effects were observed. T-scores indicated average to lower than average (39-56) responses from wildland firefighters. **CONCLUSIONS:** It is recommended that occupational psychologists be employed to enhance the coping skills training involving wildland firefighters.

2301 Board #220 May 28 2:00 PM - 3:30 PM
Sentiment Analysis Of Journal Articles, Press Releases, And News Articles Pertaining To Chronic Traumatic Encephalopathy

Kaitlyn S. Todd¹, Andrew P. Lapointe², Steven P. Broglio, FACSM¹. ¹University of Michigan, Ann Arbor, MI. ²University of Calgary, Calgary, AB, Canada. (Sponsor: Steven Broglio, FACSM)

(No relevant relationships reported)

PURPOSE: Previous research has called for media balance when reporting on chronic traumatic encephalopathy (CTE) in order to avoid harmful bias towards readers. This call is raised from concerns that the media's representation of CTE has moved beyond what science has proven. The purpose of this study was to use word sentiments to directly compare journal articles with corresponding news articles to evaluate these concerns. The news articles were split into three groups: press releases reporting the articles' findings, news articles about CTE from upper tier news outlets, and articles from lower tier news outlets.

METHODS: Research articles (n=10) directly associated with CTE that were heavily covered in the media were selected for this sample. An equivalent number of press releases (n=10), upper tier articles (n=10), and lower tier articles (n=10) were collected in order to compare semantics. The "AFINN" sentiment analysis dictionary rates the emotional valence of each word with an integer between minus three (negative connotation) and plus three (positive connotation). Words not recognized by the dictionary or with a zero weight were omitted from the analyses. Mean sentiment score was adjusted for total word count.

RESULTS: The mean sentiment scores, adjusted were words count, were as follows: 0.086 for journal articles, -0.096 for press releases, -0.122 for upper tier sources, and 0.026 for lower tier sources. An analysis of variance calculation yielded no significant differences between the groups (F = 1.058, p = 0.379).

CONCLUSIONS: Despite recent calls for a less biased reporting of CTE in mainstream media, our analysis indicates essentially equal sentimental weighting between peer-reviewed journal articles and news reports on CTE, whether the report was a press release, an article from an upper tier source, or from a lower tier source. Additionally, these sentiment weights each approached a value of zero (true neutrality). Future research should take into account the context in which the words appears in the articles in addition to using sentiment averages.

Abstract Withdrawn

2303 Board #222 May 28 2:00 PM - 3:30 PM
Does ACL-reconstruction Lead To Higher Use Of Neural Resources To Prepare & Initiate Challenging Jump-landings?

Florian Giesche¹, Solveig Vieluf², Jan Wilke¹, Tobias Engeroff¹, Daniel Niederer¹, Winfried Banzer, FACSM¹. ¹Goethe University, Frankfurt, Germany. ²Paderborn University, Paderborn, Germany. (Sponsor: Winfried Banzer, FACSM)
 Email: giesche@sport.uni-frankfurt.de

(No relevant relationships reported)

Increased cortical motor planning has been suggested to compensate the loss of mechanoreceptors after anterior cruciate ligament (ACL) injury in simple motor tasks. **PURPOSE:** To investigate the cortical processes associated with more sports- and injury-related movements. **METHODS:** Ten males with ACL-reconstructed knee (28±4 yrs., 25±3 kg/m², 63±35 months since surgery; ACLR) and 17 knee-injury free controls (28±4 yrs., 26±3 kg/m²; all males) completed 70 counter-movement jumps with single-leg landings on a pressure plate. Pre-planned (landing leg shown before take-off; PP) and non-pre-planned (visual cue during flight, 360 ms prior ground contact; NPP) landings (35 each) were performed in random order. Movement-related cortical potentials (MRCPs) were analysed to quantify the neural involvement needed to initiate the jump (higher negative potentials indicate more motor planning) using electroencephalography. The mean activity was calculated for fronto-central (FC1, FC2) and central electrodes (C3, C4, CZ) in three successive epochs prior to movement onset (acceleration sensor): Early (-1.500 to -1.000 ms; RP1), late readiness potential (-1.000 to -500 ms; RP2) and negative slope (-500 to 0 ms/movement onset; NS). **RESULTS:** In both groups, MRCPs occurred at CZ only. A 3 x 2 ANOVA revealed a main effect for a significant increase of negativity (ACLR: F(16)=36, p<0.001, eta=0.8; controls: F(9)=22, p<0.001, eta=0.6) across the three epochs (ACLR_{pp}: RP1:-0.8, RP2:-1.8, NS:-5.8 μV, p<0.01; ACLR_{npp}: RP1:-0.9, RP2:-3.2, NS:-8 μV, p<0.01; controls_{pp}: RP1:-0.2, RP2:-1.8, NS:-5.9 μV, p<0.01; controls_{npp}: RP1:-0.2, RP2:-1.1, NS:-4.3 μV, p<0.01). Between groups, no significant effects were found for time (F(26)=0.2, p=0.9), landing condition (F(26)=1.3, p=0.3) nor the interaction of both factors (F(26)=2.0, p=0.2). However, the ACLR-group showed a moderate effect for a higher negativity at all epochs in the NPP condition (d≥0.5). **CONCLUSION:** Our

jump-landing task evoked MRCPs irrespective from group and condition. The trends in our data suggest that ACLR-individuals may use more motor planning resources to initiate a challenging motor task. Research is warranted to elucidate the possible implications of such potential central compensations for injury risk. No funding.

Study On Correlation Between Cognitive Function And Exercise Intensity, Frequency And Types Of People At Advanced Age

Xiaona Cao, Yu Li. Beijing sports university hospital, Beijing, China. (Sponsor: Zhengzhen wang, FACSM)

Email: Zhengji@tsinghua.edu.cn

(No relevant relationships reported)

PURPOSE: To explore the correlation between cognitive function and exercise intensity, frequency and type of people at advanced age.

METHODS: 418 elderly people aging from 80 to 85 were recruited from Shangdi community, Haidian District, Beijing, China from April to August 2019. Based on scores of Mini-Mental State Exam (MMSE) of the elderly, the elderly were divided into normal group (≥ 27 points), cognitive impairment group (< 27 points), dementia group (Reference MMSE). To investigate sports in the past five years by surveying the elderly and their family members. Exercise intensity (refer to the "metabolic equivalent table of common daily life, entertainment and work activities") classification: 1-1.9met (eating, dressing, washing hands), 2-2.9met (walking less than 3km / h, simple housework), 3.0-4.4met (cooking, housekeeping, medium speed walking, Tai Chi), 4.5-5.9met (fast walking, jogging), > 6met (running); exercise type: housework exercise, leisure sports, sports; sports frequency: 1-2 times / week, 3-4 times / week, ≥ 5 times / week. **RESULTS:** A total of 401 effective questionnaires (96%) were collected. Except 91 of them who had interrupted their normal exercise habits due to emergencies such as diseases in the past five years, the rest 310 were investigated, including 95 cases in the normal group, 168 cases in the cognitive impairment group and 47 cases in the dementia group (mild, moderate and severe); The rate of exercise in MMSE score normal group with metabolic equivalent between 2-4.5MET was high, compared with that of cognitive impairment group and dementia group (P<0.05). Frequency of exercise in MMSE score normal group and cognitive impairment group was high, compared with that of dementia group (P<0.05). There was no correlation between the MMSE score and the type of exercise.

CONCLUSIONS: Long-term participation in the exercise with metabolic equivalent between 2-4.5met/people at advanced age can slow down the occurrence of cognitive dysfunction, so does the high exercise frequency (≥ 5 times / week). There is no evident correlation between exercise type and cognitive function of people at advanced age.

2305 Board #224 May 28 2:00 PM - 3:30 PM
Exercise's Effect On Reaction Time And Answer Accuracy During Memory Recall

Lucas Van Horn. West Chester University of Pennsylvania, West Chester, PA. (Sponsor: Dr. William A. Braun, FACSM)

(No relevant relationships reported)

Short and long-term memory recall can be improved by regular exercise, based on rat and human brain studies. Regular exercise, by promoting brain blood flow, has been shown to decrease the rate of decline of memory consolidation and recall in adults. Acute exercise can cause an immediate increase of blood flow to the brain thus potentially increasing oxidative supply for memory encoding. Conversely, a hyperglycemic state may interfere with memory encoding. **PURPOSE:** To determine the effects of light exercise (LEC), heavy exercise (HEC), and exogenous glucose (GLU) on reaction time and response accuracy during a computer-based memory recall test. **METHODS:** 15 subjects (20.80±1.26 yr) completed four trials: resting control (CON), low-intensity cycling (LEC), heavy cycling (HEC), and resting glucose (GLU): a 25% glucose solution supplied at 1g/kg of body mass followed by a 25 min rest. For each trial, subjects observed 75 images prior to the assigned treatment and were then asked to recall the images after the treatment. During the post-test, 25 images were replaced with new images; subjects were then asked to recall whether the images had been viewed during the pre-test. Accuracy and reaction time (RT) were assessed. Exercise trials (20 min) were conducted using 20% (LEC) and 40% (HEC) of Wingate anaerobic test work rate. Blood lactate, glucose, and heart rate were collected at specific time points throughout. **RESULTS:** Mean HR was significantly increased during LEC and HEC (117 ± 14.4 bpm and 161 ± 16.5 bpm, respectively) (p < 0.05) vs. CON (68.0±9.4 bpm) and GLU (67.8±7.7 bpm). Blood glucose was significantly increased during GLU (p < .001) and blood lactate significantly increased during HEC (p < .001) vs. all conditions. Despite these physiologic alterations, no main treatment effects were observed for reaction time (RT), or accuracy. However, RT was significantly faster for correct responses (1005.10 ± 22.0 ms) compared to incorrect responses (1328.2±46.5 ms) across all treatments vs. CON (p < .001).

CONCLUSION: Based on the study results, different physiologic stressors resulting from acute exercise or hyperglycemia elicited no positive or adverse effects on short-term memory recall. Though, treatments were associated with a greater RT in selecting correct responses.

A Single Bout Of Aerobic Exercise Improves Cognitive Function In Older Adults
 Haley O. Norris, Trevor M. Price, Lisa K. Sprod. *University of North Carolina at Wilmington, Wilmington, NC.*
Email: HaNorris@libertyseniorliving.com
 (No relevant relationships reported)

A Single Bout of Aerobic Exercise Improves Cognitive Function in Older Adults
 Changes in cognitive function commonly occur in older adults. These changes can range from mild cognitive impairment to dementia. With the number of older adults projected to double in the next 30 to 40 years, it is important to determine interventions capable of improving cognitive function in this sector of the population. **PURPOSE:** To determine if a single bout of moderate intensity aerobic exercise improves cognitive function in older adults. **METHODS:** Older adults were recruited from an independent living community to participate in a single 20-minute bout of moderate intensity exercise performed on a recumbent stepper. Immediately before and 10 minutes after the bout of exercise, participants completed the pattern comparison cognitive assessment to determine the impact of a single bout of aerobic exercise on cognitive function. This instrument includes 30 problems with two patterns side by side per problem where participants denote whether the patterns are the same "s" or different "d" during the 30 second time limit given. Results were scored as correct or incorrect and a higher overall score reflects better cognitive functioning. A paired-samples t-test was used to compare pre- to post-exercise cognitive function scores. Results were considered significant at $p < 0.05$. **RESULTS:** Participants included 23 adults between the ages of 69 and 94, with an average age of 81.91. Of those, 5 were males and 18 were females. There was a significant improvement from pre to post aerobic exercise in the number of correct responses on the cognitive assessment ($pre = 11.95 \pm 3.60$, $post = 13.13 \pm 2.80$, $p < 0.01$). **CONCLUSION:** A single 20-minute bout of moderate intensity aerobic exercise can improve cognitive function in older adults. With a dramatic increase in the number of older adults in the United States, research on mitigating the decline in cognitive function, such as through exercise, is imperative to meet the needs of this growing segment of the US population.

Assessment Of Neurologic Function In Mixed Martial Arts Fighters Following A Single Competition
 Thayne A. Munce, FACSM, Daniel N. Poel. *Sanford Sports Science Institute, Sioux Falls, SD.*
Email: thayne.munce@sanfordhealth.org
 (No relevant relationships reported)

Head strikes are legal and commonly used in mixed martial arts (MMA) competitions, putting MMA fighters at substantial risk for brain injury. Following a knockout (KO) or technical KO (TKO), fighters typically receive time-based medical suspensions that do not include objective determinations for safe return-to-play. Fighters who do not suffer a KO or TKO may not receive any medical suspensions, even though they may have incurred an undiagnosed concussion or subconcussive brain injury. **PURPOSE:** To determine if participating in a single MMA competition is associated with impaired neurologic function of MMA fighters. **METHODS:** Neurologic function of ten amateur and professional MMA fighters (9 men, 1 woman; 26.1 ± 2.6 yr) was assessed before (61 ± 91.8 days; T1) and after (3.8 ± 1.3 days; T2) competition. Control participants (9 men, 1 woman; 27.1 ± 2.7 yr) were assessed on two separate occasions, 38 ± 15.2 days apart (T1, T2). All participants were evaluated for static balance (Wii Balance Board; SB), dynamic balance (Y Balance Test; DB), eye movement speed and accuracy (King-Devick test; KD), near point of convergence (Vestibular / Ocular-Motor Screening; NC), hand-eye reaction time (FITLIGHT Trainer; RT), visuomotor ability (FITLIGHT Trainer, VM), and multiple object tracking speed (NeuroTracker, MOT). **RESULTS:** Two MMA participants lost their competition by KO/TKO (one due to strikes). DB, KD and NC improved significantly in control subjects relative to MMA fighters ($\beta = -0.019$, $P = 0.005$; $\beta = 2.874$, $P = 0.039$; and $\beta = 5.662$, $P = 0.002$, respectively). However, SB, RT and VM improved significantly in MMA fighters relative to control subjects ($\beta = -1.042$, $P < 0.001$; $\beta = -0.017$, $P = 0.037$; $\beta = -0.062$, $P = 0.015$, respectively). Changes in MOT between T1 and T2 were not significantly different between groups ($\beta = 0.257$, $P = 0.285$). **CONCLUSION:** MMA fighters

had deficits in some assessments of neurologic function a few days after competition, yet they seemed to improve in other aspects. Measures of dynamic balance and eye function were impaired relative to control subjects, whereas static balance and reactive movement skills were improved in MMA fighters. Overall, it appears that some aspects of neurologic function may be more susceptible to impairment following MMA competition, though general abnormalities were not present.

2308 Board #227 May 28 2:00 PM - 3:30 PM
Assessment Of Neurological Function In Mixed Martial Arts Fighters Following A Single Training Session
 Daniel N. Poel, Thayne A. Munce, FACSM. *Sanford Sports Science Institute, Sioux Falls, SD.*
Email: daniel.poel@sanfordhealth.org
 (No relevant relationships reported)

Mixed martial arts (MMA) is a combat sport that utilizes a variety of striking, grappling, and submission techniques in training and competition. Consequently, MMA fighters routinely incur head impacts that may put them at risk for mild traumatic brain injury (mTBI) and/or neurodegenerative brain disease later in life. Fighters compete rather infrequently, though often train year-round; thus, cumulative exposure to injury is higher during training than competition. However, the neurologic effects of MMA training sessions are unknown. **PURPOSE:** To determine if a single MMA training session is associated with impaired neurologic function of MMA fighters. **METHODS:** Ten amateur and professional MMA fighters (8 men, 2 women; 26.3 ± 2.6 yr) were evaluated at baseline and immediately following an MMA training session (post-training), using several objective assessments of neurologic function. Participants were evaluated for eye movement speed and accuracy (King-Devick test; KD); VOMS, near point convergence (Vestibular / Ocular-Motor Screening; NC), hand-eye reaction time (FitLight Trainer; RT), visuomotor ability (FitLight Trainer; VM), static balance (Wii Balance Board; SB), and multiple object tracking speed (NeuroTracker; MOT). **RESULTS:** Total KD times were significantly faster following a training session (35.86 ± 8.05 vs. 43.34 ± 8.92 s; $P < 0.001$). Likewise, RT (0.43 ± 0.04 vs. 0.48 ± 0.04 s; $P = 0.003$) and VM (1.06 ± 0.22 vs. 1.20 ± 0.25 s; $P = 0.011$) times improved significantly following training. MOT speed (2.15 ± 0.26 vs. 2.03 ± 0.34 m·s⁻¹; $P = 0.442$) and NC distance (5.18 ± 5.12 vs. 6.62 ± 5.85 cm; $P = 0.284$) also improved following training, although these changes were not significant. SB was virtually identical from baseline to post-training (2.27 ± 0.95 vs. 2.27 ± 1.30 cm²; $P = 0.994$). **CONCLUSION:** Compared to baseline measures, some assessments of neurologic function revealed significant changes after a single MMA training session. Contrary to what was expected, all significant changes were the result of improved performance from baseline to post-training. Based on these findings, neurologic function of MMA fighters does not appear to be impaired following a single training session. Furthermore, MMA training bouts may be associated with acute improvements in eye movement, reaction time and visuomotor ability.

2309 Board #228 May 28 2:00 PM - 3:30 PM
Smooth Pursuit And Saccadic Eye Movements Following Years Of Contact Collision Sports: A Pilot Study
 Nicholas G. Murray, Brian Szekely, Arthur Islas, Cameron Kissick, Philip Pavilonis, Sushma Alphonsa, Madison R. Taylor, Nora Constantino. *University of Nevada, Reno, Reno, NV.*
Email: nicholasmurray@unr.edu
 (No relevant relationships reported)

Repetitive head impacts (RHI) are the result of a blow to the head that does not elicit clinical signs or symptoms of a concussion. Recent evidence suggests that RHI from a single season of collegiate football can lead to a reduction in midbrain white matter integrity. The midbrain carries projecting fibers to the trochlear and oculomotor nerves, which if damaged may impair oculomotor control. **PURPOSE:** The purpose of this study was to evaluate oculomotor function following multiple years of Division I contact sports during a dynamic visual acuity (DVA) task. **METHODS:** Two NCAA Division I football defensive backs with no diagnosed concussion history (a first-year freshman [F1; age=18 years], senior [S1; age=21 years]) and a healthy control (CON; age=23 years), all with lower than 20/20 vision, completed a DVA task at pre-season. For the DVA task (optotype spatial range=1.0 to -0.3), participants were asked to complete 60 randomized trials of smooth pursuit (30°/s) and saccades (150°/s). Participants head were stabilized in a chin rest at a distance of 154cm away from the 26° visual field monitor (165Hz, 2560 x 1440 pixel resolution, 300 cd/m² luminance) while wearing a head-mounted binocular video ophthalmography eye tracker (Eyelink SR research, 500 Hz, Ottawa, CN). Using a 2-up-1-down staircase method, participants tracked a Landolt-C ring that moved across the screen (horizontally left to right) where the size of the gap in the C along with the orientation (left, right, up or down) adjusted based on the correct/incorrect responses during both smooth pursuit and saccadic trials. Smooth pursuit eye movement (SPEM) velocity gain and saccadic peak velocity were calculated using ternary eye movement classification from the transformed spherical coordinates via a custom MATLAB code (MATLAB 2019a, Natick, MA, USA).

No statistical analysis were performed given the single-subject design. **RESULTS:** SPEMs gain is lower for S1 (0.88) when compared to F1 (0.82) and CON (0.92). Similarly, during the saccadic trials, S1 had slower average saccadic peak velocity (S1=279.75°/s; F1=392.34°/s; CON=491.96°/s). **CONCLUSIONS:** These results may indicate that engaging in contact collision sport for 2+ years at the Division 1 level may result in less accurate (lower SPEMs gain) and slower saccadic eye movements. Supported by NIH P20GM103650

Submaximal Exercise Does Not Increase Brain-Derived Neurotrophic Factor (BDNF) In People With Spinal Cord Injury

Jeremy J. Walsh, Kendra R. Todd, Kathleen A. Martin Ginis, Jonathan P. Little, FACSM. *University of British Columbia, Kelowna, BC, Canada.* (Sponsor: Jonathan Little, FACSM)
 Email: jeremy.walsh@ubc.ca
 (No relevant relationships reported)

Brain-derived neurotrophic factor (BDNF) has been implicated in repair and regeneration of peripheral neurons, and is important for brain health. Acute exercise (EX) increases circulating BDNF in an intensity dependent manner in able-bodied individuals. However, the response of BDNF to EX in people with spinal cord injury (SCI) is poorly understood. **PURPOSE:** to investigate the hypothesis that submaximal EX will increase serum and plasma BDNF in people with SCI. **METHODS:** Nine adults with SCI participated (M age = 39.2 ± 11.0 years; M years post-injury = 16.5 ± 9.2). After completing a maximal exercise test on an electromagnetically braked arm-crank ergometer to determine peak power output (PPO), participants completed two visits in randomized order: 1) submaximal EX (30 minutes maintaining 55-65 rpm @ 60% PPO); and 2) seated control (CTL). Ratings of perceived exertion (RPE) were measured during EX using the 6-20 visual Borg RPE scale. Heart rate (HR) and blood pressure (BP) were measured pre- and post-EX. BDNF was measured via ELISA in both serum and plasma from venous blood sampled at pre-, post-, and 90 min post-EX. For the CTL visit, participants rested quietly for 120 min and blood was sampled at equivalent time points to EX. A 2-factor repeated measures ANOVA was computed to assess BDNF responses by time and condition. Paired t-tests were computed to assess HR and BP responses to EX. Pearson correlations were computed to explore relationships between BDNF and physiological responses to EX and work rate. **RESULTS:** The average EX work rate was 47 ± 17 W and RPE was 13 ± 1. HR increased by 26 ± 33 bpm (+41%; p=0.059), whereas systolic and diastolic BP remained unchanged after EX. Contrary to our hypotheses, EX had no effect on serum (Pre vs. Post-EX = 22447.9 ± 9071.1 pg/mL vs. 26552.8 ± 6563.4 pg/mL; $F_{(1,12)} = 0.51$, p=0.53) or plasma (Pre vs. Post-EX = 1802.7 ± 1031.1 vs. 1662.7 ± 1390.0 pg/mL; $F_{(1,10)} = 0.77$, p=0.45) BDNF. Exploratory correlational analyses showed no relationships between changes in BDNF and the outlined parameters. **CONCLUSIONS:** Submaximal EX did not increase BDNF in people with SCI. Future studies should systematically investigate BDNF responses to higher EX intensities given the intensity-dependent response in able-bodied people. **FUNDING:** Rick Hansen Foundation through the Blusson Integrated Cures Partnership

Beyond The Runners High: Cannabis And Exercise
 Whitney Ogle, Lukas Coppen, Claire Copriviza. *Humboldt State University, Arcata, CA.*
 (No relevant relationships reported)

Cannabis use has been gaining wider social acceptance, and with increased legalization cannabis users are talking more openly about how and why they consume cannabis. While there is growing interest in combining cannabis with physical activity, there is a distinct lack of cannabis research in humans, particularly as it relates to physical activity. **PURPOSE:** To investigate how and why people use cannabis with exercise as well as categorizing the types of exercise users engage in. **METHODS:** 126 subjects (n = 63 male, 62 female, 1 non-binary) were recruited to complete an anonymous online survey if they reported both participation in regular physical activity and cannabis use. The survey consisted of five sections: cannabis with exercise, general exercise participation, general cannabis use, unanticipated experiences, and demographics. **RESULTS:** Over 44% of participants reported that they use cannabis every or almost every time before they exercise. Most smoke cannabis (53%) and use Sativa-dominant strains (65%) before exercise. Only 18% of participants used non-psychoactive CBD products during exercise. The highest reports of exercise participation under the influence of cannabis include hiking (61%), yoga (58%), aerobic machines (50%), walking (43%), and weight lifting (43%). The primary reasons for using cannabis before exercise include: helps me focus/concentrate (66%), helps me enjoy exercise (65%), enhances mind-body-spirit connection (64%), keeps me in the zone (61%), and enhances body awareness (52%). The majority (70%) of respondents reported feeling

more satisfied with their workouts under the influence of cannabis compared to when they do not use cannabis prior to exercise and have not suffered any unanticipated experiences (61%). **CONCLUSIONS:** This is the first study to investigate how and why people use cannabis with exercise. This study provides a starting point for future studies investigating the impact that cannabis consumption has on exercise participation and performance.

2312 Board #231 May 28 2:00 PM - 3:30 PM
Impact Of Exercise Intensity On Cue Reactivity In Heavy Alcohol Users

Kelly Miller, Kathleen Cashman, Abigail Nerenhausen, Kelsey Manzano, Stephen Folger, Stephen Bailey, FACSM. *Elon University, Elon, NC.* (Sponsor: Stephen Bailey, FACSM)
 Email: kmiller61@elon.edu
 (No relevant relationships reported)

Physical exercise has been shown to reduce craving for alcohol in alcoholics. There is a high prevalence of heavy alcohol use in college-aged adults (18-29 years of age). This can be predictive of an alcohol or other substance use disorder developing later in life. Acute exercise alters cue reactivity to addictive substances but it is unknown if the magnitude of change in cue reactivity is impacted by exercise intensity. **PURPOSE:** The purpose of this investigation is to examine the impact of acute aerobic exercise of varying intensities on cue reactivity to alcohol in heavy alcohol users. **METHODS:** Nine participants (8 females, 1 male) (Age = 21.5 ± 0.5 years, BMI=23.9 ± 0.1, $VO_{2Max}=32.25 \pm 1.06$ ml·kg⁻¹·min⁻¹) completed 3 experimental sessions. Heavy alcohol use was identified using an adapted version of the CAGE questionnaire. During one session subjects rested (REST) for 30 minutes and during the other two sessions subjects exercised for 30 minutes at a moderate (MOD: 53 ± 7% of Peak HR) or vigorous (VIG: 76 ± 2% of Peak HR) exercise intensity. Sessions were randomized for each participant. Prior to and immediately following each session, EEG data were collected using a 64-channel system while subjects were exposed to 210 images (90 alcoholic drinks (ALC), 90 non-alcoholic drinks (NON), 30 control images). Images were presented in a random order and proceeded by a fixation stimulus using a variable time span (0.5 to 1.5 sec). Adaptive mean amplitude for P300 (210-240 ms post stimulus) and mean amplitude for the late positive potential (LPP) (400-600 ms post stimulus) were calculated in parietal-occipital electrodes. **RESULTS:** The P300 response to ALC increased from pre to post in both REST (pre=2.69 ± 0.72 μV, post=3.41 ± 0.52 μV; p=0.002) and VIG (pre=1.62 ± 0.40 μV; post=2.95 ± 0.51 μV, p<0.001) conditions. In comparison, the P300 response to ALC decreased in the MOD (pre=1.31 ± 0.29 μV; post=0.66 ± 0.32 μV, p<0.001) condition. The LPP to ALC was much greater after REST (2.55 ± 0.69 μV) than after MOD (-0.10 ± 0.32 μV; p<0.001) and VIG (0.73 ± 0.78 μV; p=0.003). **CONCLUSION:** These findings suggest that the impact of exercise on cue reactivity to images of alcohol in heavy alcohol users is dependent on exercise intensity. Specifically, it appears that moderate intensity exercise has a greater benefit than vigorous exercise.

Age Of First Exposure Influences Cerebrovascular Reactivity In High School Football Athletes
 Patricia R. Roby, Jason P. Mihalik, FACSM. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*
 Email: pcombs@live.unc.edu
 (No relevant relationships reported)

Late-life physiological and clinical impairments are associated with age of first exposure (AFE) to tackle football. There is a dearth of literature describing how AFE may influence physiological outcomes in current high school football athletes. Cerebrovascular reactivity (CVR) measures the cerebral blood flow response to variations in carbon dioxide partial pressures. Understanding how AFE affects cerebrovascular function in high school athletes may offer insight into potential long-term deficits following cumulative head impact exposure. **PURPOSE:** To investigate how the age at which high school football athletes began playing tackle football influences baseline CVR. **METHODS:** High school football athletes [n=29; age=15.8 ± 1.1 yrs; height=175.8 ± 8.1 cm; mass=75.1 ± 12.6 kg] self-reported AFE (median AFE=13 years old, range=5-15). Transcranial Doppler (TCD) ultrasound was used to assess middle cerebral artery velocity (MCAv) prior to beginning the competitive season. Baseline MCAv was collected for 2 minutes. Changes in MCAv were measured in response to 5 breath-holding trials (20s breath-hold/40s rest) and 5 hyperventilation trials (20s hyperventilation/40s rest). We employed separate mixed effects models with quadratic mean structures to assess group differences in MCAv response to breath-holding and hyperventilation tasks. **RESULTS:** The AFE significantly predicted CVR during breath-holding ($F_{(1,170)}=5.27$, p=0.02) and hyperventilation ($F_{(1,170)}=4.08$, p=0.04). One-year increases in AFE were associated with a 0.69% reduction in average CVR response during breath-holding and a 0.58% increase in average CVR during hyperventilation. **CONCLUSIONS:** Though AFE is associated with CVR in high school football players, the underlying mechanisms driving the observed results

are unclear. The effect of cumulative head impact exposure at the high school level is understudied despite long-term neurophysiological deficits reported in retired professional football players. Studying neurophysiological responses in young football players may provide important insights into addressing cerebrovascular function and other late-life physiological health in athletes.

Validation Checks Decrease Sandbagging On Baseline Neurocognitive Tests

Melissa A. Fraser. *Texas State University, San Marcos, TX.*
 Email: missyfraser@txstate.edu
 (No relevant relationships reported)

PURPOSE: To examine whether a second baseline test (Group 2B) in those scoring an invalid first test on CNS Vital Sign (CNSVS) is comparable to those achieving a valid baseline initially (Group 1).

METHODS: This is a retrospective cohort of 817 Division I collegiate student-athletes ages 17-26 who completed at least one valid baseline examination. Subjects were asked to complete a pre-participation computerized neurocognitive test (CNSVS) and those with invalid baseline exams were retested. The valid scores for the retest-group (Group 2B) were compared to subjects who earned a valid baseline exam on their first visit (Group 1). Standard scores were included for all CNSVS domains. The mean scores for all outcome variables of Group 1 and Group 2B were compared using ANOVA analyses with significance set at $p=0.05$.

RESULTS: In the majority (11/13) of cognitive test scores, subjects with an initial invalid baseline performed similarly in their second attempt (Group 2B) compared to subjects who had a valid baseline exam after one attempt (Group 1). The general memory (92.17 ± 15.56) and visual memory (93.26 ± 13.21) scores for Group 2B remained significantly lower than Group 1 (99.96 ± 15.15 ; 101.33 ± 13.97) ($p=0.015$, $p=0.006$), respectively, while motor speed for the re-test group (109.91 ± 12.48) was significantly higher than Group 1 (102.90 ± 12.30) ($p=0.02$). Interestingly, the total test time (seconds) and the testing duration (seconds) were significantly faster ($p < 0.001$; $p=0.008$) during the second testing session (Group 2B = 1745.74 ± 205.72 ; 1599.09 ± 196.59) compared to the those who earned valid scores in their initial attempt (Group 1 = 2042.53 ± 276.76 ; 1693.53 ± 167.16) respectively.

CONCLUSIONS: Subjects initially completing an invalid baseline examination for concussion testing show significantly worse results than their peers who complete valid baseline tests initially, but these poor results do not persist when given a retest. When computerized neurocognitive tests include validity measurements, "sandbagging" of results can be significantly mitigated, improving overall accuracy of post-injury concussion monitoring, thus decreasing the probability of returning an athlete too early following a concussive injury.

NEUROPHYSIOLOGICAL CHANGES AFTER UPPER AND LOWER LIMB GRADED EXERCISE TESTING.

Anthony Colvard, Daryl L. Parker, Matt JN Brown. *California State University, Sacramento, Sacramento, CA.*
 Email: anthonycolvard@csus.edu
 (No relevant relationships reported)

Aerobic exercise, including graded exercise testing (GXT), may cause neurophysiological changes of circuits in the primary motor cortex (M1) related to mechanisms of fatigue and/or plasticity. Investigating M1 inhibitory circuit changes over time in exercising compared to non-exercising muscles after GXT of the upper limbs (UL) and lower limbs (LL) may distinguish between different post-exercise mechanisms. **PURPOSE:** To evaluate M1 inhibitory circuit changes resulting from UL and LL GXT and determine their associations with fitness. **METHODS:** Six healthy subjects (30 ± 6 yrs) participated. Transcranial Magnetic Stimulation (TMS), Peripheral Nerve Stimulation (PNS), and Electromyography (EMG) were used for neurophysiological testing. Gas analysis was performed to evaluate VO_{2max} (UL: 24.2 ± 4.8 , LL: 35.1 ± 5.9 mL/kg/min) during GXTs. Surface electrodes were placed over the first dorsal interosseous (FDI) and tibialis anterior (TA) muscles. Measures of M1 and M1-related afferent inhibition included cortical silent period (CSP) and short-latency afferent inhibition (SAI), respectively. SAI inter-stimulus intervals (ISI) between PNS and TMS stimulations were 21-23ms (UL), and 32-35ms (LL). TMS coil orientation (CO) was altered between posterior-anterior (PA) and anterior-posterior (AP) for both measures of CSP and SAI. CSP and SAI were taken 0-45 min (POST1) and 45-90 min (POST2) post-exercise and compared to pre-exercise. Repeated measures ANOVAs were performed to evaluate effects of exercise type, CO, time, and ISI. **RESULTS:** CSP decreased at POST1 and increased at POST2 in FDI ($97.9 \pm 1.2\%$ vs. $104.5 \pm 2.5\%$, $p < 0.05$) with a trend toward significance in TA ($99.3 \pm 2.5\%$ vs. $103.5 \pm 4.9\%$, $p = 0.19$). Although SAI was found for the TA at 32ms ($p < 0.05$) and FDI at 21-23ms ($p < 0.05$), the interaction of exercise type, CO, and ISI did not reach significance after Huynh-Feldt correction (FDI: $p = 0.10$, TA: $p = 0.10$). Univariate linear regression of VO_{2max} and SAI revealed a potential relationship reliant on exercise type and CO (UL: $R^2 = 0.91$, LL: $R^2 = 0.68$). **CONCLUSIONS:** Changes in

CSP suggest that exercise may cause early disinhibition followed by greater inhibition in M1 while changes in SAI may be influenced by fitness levels. Collectively, the results support UL and LL GXTs cause measurable M1 neurophysiological changes.

Vestibular, Spatial Cognition And Mental Fatigue Status Of Female Soccer Players Before A Competitive Season

Linda J. D'Silva, Jackson J. Mores, Jeremiah J. Diaz, Aaron Carbuhn. *University of Kansas Medical Center, Kansas City, KS.*
 Email: ldsilva@kumc.edu
 (No relevant relationships reported)

PURPOSE: To examine visual-vestibular interaction and the relationship to visuospatial cognition, mental fatigue, and concussion history in female soccer players before the start of a competitive season. **METHODS:** Twenty-four NCAA Division 1 women's soccer athletes participated in the study. All players completed medical history including dates and number of prior concussions. Vestibular and visual interaction was assessed using the Dynamic Visual Acuity Test (DVAT) which examines the loss in visual acuity when the head is moving in the yaw plane at 85 deg/sec or more compared to head stationary. Visuospatial cognition was assessed using the Symbol Digit Modalities Test (SDMT) and the Ray-Osterrieth Complex Figure (ROCF) while current fatigue level was assessed using the Mental Fatigue Scale (MFS). Spearman's correlations examined the correlations between DVAT loss and MFS, SDMT, and ROCF. Comparison of MFS, SDMT score, and ROCF score between groups based on number of concussions was completed using t-tests.

RESULTS: Of the 24 participants (mean age 19.3 ± 1.3), 15 had a prior history of concussion (range 1-7). Mean loss of visual acuity in the pitch plane in logMAR upwards was 0.14 ± 0.08 and downwards was 0.19 ± 0.1 , and in the yaw plane was 0.15 ± 0.08 to the right and 0.14 ± 0.1 to the left (normative values for this age group are 0.08 ± 0.17 logMAR). The SDMT score was 59.88 ± 6.7 , ROCF score was 29.9 ± 5.4 , and MFS score was 6.9 ± 5.8 . Spearman's correlations showed significant relationships between DVAT loss to the right ($p=0.04$) and mental fatigue ($p=0.04$). Comparisons of athletes who had sustained 2 or more concussions compared to those with 0-1 showed significant differences in the MFS ($p=0.03$).

CONCLUSIONS: Greater loss of dynamic visual acuity was seen in female soccer players before the start of a competitive season. Gaze stability deficits are correlated with higher mental fatigue and athletes who had 2 or more concussions had more mental fatigue.

Stress Response And Performance Changes Of Law Enforcement Officers' Marksmanship Under Varied Levels Of Stress

Brandon Michael Male, Judith M. Lukaszuk, Peter J. Chomentowski, III, David A. Walker. *Northern Illinois University, DeKalb, IL.* (Sponsor: Craig E. Broeder, FACSM)
 Email: bmale2@niu.edu
 (No relevant relationships reported)

PURPOSE: To investigate changes in shooting performance of law enforcement officers under varying levels of stress. This study determined how increasing levels of stress from operating a firearm on static targets changed when participants were subjected to simulated life threatening situations.

METHODS: Thirteen law enforcement officers completed three trials of handgun shooting trials using a battery-operated laser marking pistol. Trial one included a modified course from the Illinois State Firearms Qualification Course of Fire. Officers completed two separate simulation trials separated by 48 hrs (SIMCON1, SIMCON2). Each officer engaged in dangerous encounters with virtual suspects using a TI Simulator (TI Training, Golden, Colorado) requiring each officer to draw his weapon and fire against an armed assailant. Heart rate, blood pressure, salivary cortisol, and shooting performance data were collected throughout the courses of fire.

RESULTS: Compared with the qualification course of fire (99.23% hit rate of intended target), there was a statistically significant reduction $p < .001$ in percentage of shots hit during both SIMCON1 (hit rate 47.48%) and SIMCON2 (hit rate 50.13%) conflicts. Compared to trial 1 mean heart rate increased 16.46 BPM and 19.7 BPM and systolic blood pressure 18.77 mm Hg and 23.08 mm Hg respectively for SIMCON1 and SIMCON2 trials. Although a significant physiological effect was noted following both SIMCON trials, it did not statistically correlate with poor marksmanship performance.

CONCLUSIONS: Future research should collect physiological variables such as heart rate and blood pressure when the officers are on duty. This real-life situation would likely heighten the physiological responses versus that of simulated setting used in this study. It may provide better insight how real-life scenarios may negatively affect marksmanship performance.

Effects Of Treadmill Exercise On DCX And A Beta1-42 In AD Mice

Zhang Ye-ting¹, Li Xue¹, Fu Yan², Yuan Qiong-jia¹. ¹Chengdu Sport Institute, Chengdu, China. ²Southwest Minzu University, Chengdu, China.
 (No relevant relationships reported)

PURPOSE: To investigate the effects of different load exercise on the hippocampal neurogenesis markers DCX and Aβ1-42 in adult AD mice.

METHODS: The 3-month-old APP/PS1 dual-transgenic AD mice were randomly divided into four groups: Control group(ADC), Low-load exercise group(ADL), Medium-load exercise group(ADM) and High-load exercise group(ADH), Wild-type control group(WTC) was also set, 6 mice in each group. ADC and WTC group mice were fed naturally for 5 months. Intervention with different loads of aerobic exercise for every exercise group. Low load running speed was 12 m/min, medium load running speed was 15 m/min, and high load running speed was 18m/min. 5d/w for 30 min/d for 5 months. Then, the Morris Water Maze (MWM) test was performed to estimate mice' learning and memory abilities, the immunofluorescence technique was used to determine the expression levels of DCX and Aβ1-42 in the hippocampus.

RESULTS: (1) In the process of navigation training, all mice' escape latencies gradually shortened. On the second day, the average escape latency of the ADC group was significantly higher than that of the WTC group ($p<0.05$). Compared with the ADC group and the ADL group, the mice in the ADM group were significantly reduced from the third day, and the mice in the ADH group were significantly reduced from the fourth day ($p<0.05$). In the MWM navigation experiment, for the time of through the area of the original platform, ADC group was significantly reduced than WTC group ($p<0.01$), ADM group and ADH group was significantly higher than ADC group and ADL group ($p<0.01, p<0.05$). (2) Compared with WTC group, the expression of DCX in ADC group was lower but Aβ1-42 was higher ($P<0.05$). Compared with ADC group, the expression of DCX in every exercise group was higher but Aβ1-42 was lower ($P<0.05, P<0.01$). Compared with ADL group, the expression of DCX in ADM group was higher but Aβ1-42 was lower ($P<0.05$).

CONCLUSIONS: Medium and high load exercise can significantly improve the spatial learning and memory ability of AD mice. Exercise, especially medium load exercise, can enhance the expression of DCX in AD mice and reduce the expression of Aβ1-42 in hippocampal.

2319 Board #238 May 28 2:00 PM - 3:30 PM
Effects Of Acute Aerobic Exercise On Working Memory Of Male Smoking College Students: An Erp Study

Guoyuan Huang¹, Zhao Xu², Yingying Zhang², Hao Wang², Crystal Steltenpohl¹. ¹University of Southern Indiana, Evansville, IN. ²Shandong Sport University, Jinan, China.
 (No relevant relationships reported)

PURPOSE: Studies have shown a relationship between acute exercise and working memory among smokers. However, how acute aerobic exercise affects working memory of smoking college students is still under-researched. The current study was to explore the impact of different intensities of acute aerobic exercise on the working memory using behavioral and ERP assessment.

METHODS: Male smoking college students (n=64) aged 18-22 yrs were randomly selected. After signing the informed consents, they were assigned to a control group with 25-min reading at rest and three cycling exercise groups at light, moderate and high intensity. All participants completed a letter delay- and a space position delay-matching task pre- and post- intervention, both programmed in E-prime software. Reaction time and performance accuracy were measured. ERPs were recorded by NeuroScan EEG system. Amplitude and latency at FZ, FCZ, CZ, and PZ were collected by Curry 7 software. Statistical analyses were conducted with repeated measures ANOVA using SPSS 20.0. An alpha level was set at $P\leq 0.05$.

RESULTS: Three exercise groups had significantly shorter reaction times ($p<0.001$) and higher performance accuracy ($p<0.001$) in both tasks, compared with the control. Moderate exercise exhibited the best scores in both tasks. All exercise groups showed significantly higher accuracy scores in spatial working memory task than those verbal scores. ERP data revealed changes as follow: 1) significant differences were observed in N2 amplitude at FZ ($p=0.048$) and FCZ ($p=0.017$) and in P3 amplitude at FZ ($p=0.002$), FCZ ($p=0.000$), CZ ($p=0.002$) and PZ ($p=0.008$); 2) significant differences were found between different type of stimulus tasks, in N2 latency at FCZ ($p=0.045$) and PZ ($p=0.049$) and in P3 latency at FZ ($p=0.022$), FCZ ($p=0.013$), and CZ ($p=0.014$); 3) all exercise groups exhibited shorter P3 latency than the control at FCZ ($p=0.040$) and CZ ($p=0.031$) with the moderate and high intensity groups showing the shortest.

CONCLUSIONS: Acute aerobic exercise could improve male smoking college students' working memory, attention resource utilization, and cognitive processing speed. Moderate intensity exercise may have the greatest influence on these parameters. Acute aerobic exercise may have beneficial effects on cognition at behavioral and neuroelectric levels.

Prefrontal Theta Rhythm As An Index Of Effortful Activity

Nathalie André, Michel Francis Audiffren, Angele Metais, Thomas Mangin, Abdel Benraiss. *University of Poitiers, Poitiers, France.* (Sponsor: Phillip Tomporowski, FACSM)
 Email: nathalie.andre@univ-poitiers.fr
 (No relevant relationships reported)

Cognitive tasks that tap executive functions and uncomfortable strenuous physical tasks require a deployment of mental effort. Several psychophysiological studies propose different indexes of this engagement in mental effort: for instance, pupillary dilation, power density of high frequency in heart rate variability, and pre-ejection period. More recently, it has been suggested that slow waves (4-8 Hz) recorded above prefrontal areas may also be a good candidate to assess effort engagement. **PURPOSE:** To determine whether theta oscillations recorded above prefrontal areas are a good index of mental effort deployed in a handgrip task. **METHODS:** Sixteen young voluntary adult participants performed three consecutive tasks in the same session: (1) a handgrip task in which they have to maintain an isometric contraction at 13% of maximal voluntary contraction (MVC) until exhaustion (H1), (2) a 30-min Stroop task aiming to deplete self-control resources and (3) the same handgrip task as previously (H2). A Biosemi system was used to amplify and record electroencephalographic (EEG) and electrooculographic (EOG) signals throughout the experiment. The sampling frequency of EEG was 2000 Hz and the bandwidth ranged between 0.1 and 40 Hz. **RESULTS:** A MANOVA was carried out with Time on task (TOT; T1-T4), Task (H1, H2), and Electrodes location (Fpz, AFz, Fz, FCz, Cz) as repeated measures factors on theta waves spectral density ($\mu V^2/Hz$) recorded during the handgrip task. Theta wave density significantly increased between T1 and T2 and between T3 and T4, during both handgrip tasks (H1 and H2). There was also a significant interaction between the Electrode location and the Handgrip task. Theta wave density was higher during H1 than H2 and this effect was larger on Fpz than on the other electrodes. Perceived effort, pain and fatigue significantly increased throughout both handgrip tasks. Perceived fatigue was higher after H2 than H1. **CONCLUSION:** As expected, theta wave spectral density increased with time on task and particularly above prefrontal areas. However, it is difficult to determine if this biomarker reflects an increase in mental fatigue throughout the task or an increase in mental effort to compensate for the increase in mental fatigue.

Task-specificity Of Corticospinal Excitability: The Influence Of Contractile Properties

Felix Proessel, Maria C. Canino, Adam J. Sterczala, Brandon M. Sciavolino, Courtenay Dunn-Lewis, William R. Conkright, Aaron M. Sinnott, Meaghan E. Beckner, Shawn R. Eagle, Fabio Ferrarelli, Anne Germain, Chris Connaboy, Bradley C. Nindl, FACSM, Shawn D. Flanagan. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Dr. Nindl, FACSM)
 Email: fsp5@pitt.edu
 (No relevant relationships reported)

Transcranial magnetic stimulation (TMS) is increasingly applied to investigate neurophysiological function during exercise interventions. Although often assessed in testing modalities that are different than the intervention, neurophysiological function may be task-specific. **PURPOSE:** To compare neurophysiological function between an isometric squat (SQT) and knee extension (KE). **METHODS:** Twenty-two young adults (2 women, 20 right-footed, age: 25 ± 5 yrs, BMI: 25.9 ± 3.1 , VO_2 : 46.2 ± 8.8 ml·kg⁻¹·min⁻¹) performed isometric SQT (N=7) or KE (N=15), with hip-, knee- and ankle-joints fixed at 90° as part of a larger study, exposing participants to operational stress for a 5-day period. Lower extremity strength and muscle activity (RMS) were recorded during maximum voluntary contractions (MVCs), using a linear force transducer and electromyography (EMG) sensors placed over the vastus lateralis, respectively. Motor-evoked-potential (MEP)-based stimulus response curves (SRC) were derived using TMS and a double cone coil placed over the dominant motor cortex leg hotspot during intermittent isometric contractions at 15% MVC. Forty stimuli were applied for two rounds of SRC, with stimulator output (SO) ranging from 5-100% in 5% increments and random order. Since neurophysiological function did not differ across days, grand averaged responses were compared using multivariate ANOVAs or Mann-Whitney U. **RESULTS:** Greater force and muscle activity were evident for KE compared to SQT (Force: 1303.9 ± 407.0 vs. 812.8 ± 189.5 N, $p=0.01$; EMG_{RMS} : 0.04 ± 0.003 vs. 0.06 ± 0.01 , $p=0.03$). KE corticospinal excitability was twice as high compared to SQT (1.4 ± 0.7 vs. 0.7 ± 0.4 mV, $p=0.04$), but similar when normalized to muscle activity (KE: 25.3 ± 13.9 vs. SQT: 17.4 ± 10.7 mV·EMG_{RMS}⁻¹, $p=0.21$). No difference was evident in SRC₅₀ and SRC_{SLOPE} (54 ± 9 vs. $62\pm 14\%$, $p=0.12$ and 5.0 ± 1.9 vs. 4.2 ± 1.1 , $p=0.35$). **CONCLUSION:** Contractile and corticospinal excitability appear to be task-specific, discouraging the assessment of neurophysiological function in modalities that are different from the intervention. Contractile function further seems

to influence corticospinal excitability, which may reflect the underlying differences in neuromechanics between the two movements. Supported by the Department of Defense W81XWH-16-PHTBIRP-CR3A.

FRONTAL ASYMMETRY: A POTENTIALLY NOVEL BIOMARKER FOR SEDENTARY BEHAVIOR

Battogtokh Zagdsuren¹, Hunter Threadgill², Hayley V. MacDonald¹, Mark Richardson¹, Philip Gable¹. ¹The University of Alabama, Tuscaloosa, AL, ²Florida State University, Tallahassee, FL.
(No relevant relationships reported)

Consistent with other human behaviors, sedentary behavior appears to be modulated, at least in part, by emotional and motivational processes. Past research has found that various emotion and motivation interactions show different patterns of asymmetric frontal cortical activity (FCA). It is possible that the decision, motivation, or the intention to engage in sedentary behavior may depend on the FCA. However, FCA has yet to be investigated as a potential neurobiological marker to predict sedentary behavior. **PURPOSE:** To examine the relationship between sedentary behavior and resting frontal asymmetry using electroencephalography (EEG). **METHODS:** Forty-five college students participated in this study in exchange for partial course credit. A modified short version of the International Physical Activity Questionnaire was administered to determine habitual level of physical activity and sedentary time. Standard processing of EEG data was performed using BrainVision Analyzer software. Univariate correlation analyses were used to examine the relationship between frontal asymmetry and sedentary time. **RESULTS:** Average number of minutes spent sitting on a weekday ($r(22) = -0.45, p = 0.027$) and on a weekend day ($r(22) = -0.55, p = 0.005$) correlated with relative left frontal activity. **CONCLUSION:** To our knowledge, our data are the first to find a link between neurobiological markers of approach/avoidance motivation and sedentary activity, suggesting that reduced left frontal activity might be a novel neurophysiological marker for sedentary behavior.

Test-retest Reliability Of Cognitive And Neuroimaging Measures In Older Adults

Timothy R. Macaulay, Judy Pa, Dominique Duncan, Jason Kutch, Lirong Yan, Christianne Lane, E. Todd Schroeder, FACS. *University of Southern California, Los Angeles, CA.*
Email: tmacaula@usc.edu
(No relevant relationships reported)

PURPOSE: Exercise is a promising strategy to help maintain brain function during aging. Determining the efficacy of exercise interventions requires reliable clinical outcome measures. In addition to measurement error and biological variability, long-term test-retest values can also be influenced by biasing factors - namely aging and practice effects. The purpose of this study was to determine the 12-week test-retest reliability of cognitive and neuroimaging measures in older adults. **METHODS:** Twenty healthy older adults (14 females, 60-80 years of age) participated in two sessions of cognitive testing and multimodal 3T MRI scanning (Siemens MAGNETOM Prisma). All tests were performed by a single rater separated by a 12-week control period. The NIH Toolbox Cognition Battery (NIHTB-CB) was used to assess fluid and crystallized cognitive function. T-2 FLAIR images were processed for white matter lesion volume (WMLV, ml) using the Lesion Segmentation Toolbox. T-1 MPRAGE images were processed for gray matter volume (GMV, mm³) in 3 subcortical regions using FrecSurfer cortical segmentation. Statistical analyses were performed in SPSS (v.25) including mean percent difference, effect size, paired t-test, and two-way mixed intraclass correlation coefficient (ICC) with absolute agreement. **RESULTS:** Results are presented in Table 1. There were no significant t-test values indicating good agreement between the two sessions. As expected, reliability was excellent in crystallized cognition and moderate to good in fluid cognition. Last, all brain segmentations showed good to excellent reliability. **CONCLUSIONS:** The long-term (12-weeks) test-retest reliability of standard cognitive and neuroimaging measures were within an acceptable tolerance for use in future intervention studies. Although fluid cognition has the greatest implications for and neurobiological link to cognitive aging, investigators should consider the greater variability in these measures.

Aerobic Fitness Is Associated With Greater Cortical Thickness In Functional Connectivity Networks

Daniel R. Westfall¹, Michael B. Kranz², Charles H. Hillman¹, Edward McAuley², Arthur F. Kramer¹. ¹Northeastern University, Boston, MA, ²University of Illinois, Urbana-Champaign, IL.
Email: westfall.d@husky.neu.edu
(No relevant relationships reported)

Purpose: This study investigated the associations between cortical morphometry of functional connectivity networks and aerobic fitness (AF) in aging adults. **Methods:** Older adults (60-80 yrs; n=205) completed a graded exercise test to measure AF and a structural MRI. Cortical thickness was calculated and parcellated into 7 functional connectivity networks (Yeo et al., 2011). The associations between AF and thickness were investigated by calculating 5000 bootstrapped samples of a correlation coefficient between AF and either whole brain or network parcellated cortical thickness. Age and sex were used as covariates. Whole-brain exploratory analysis was conducted to examine the spatial extent of network morphometry and AF. First, correlation coefficients for each vertex and AF were calculated and bootstrapped. Next, a shuffled distribution was calculated across 100,000 permutations and the proportion of permutations greater or equal to the number of significant vertices was used to assess significance. **Summary of Results:** Greater AF was associated with greater whole brain cortical thickness ($r = 0.29, p < .001, 95\% CI [0.17 0.41]$), greater cortical thickness in the visual ($r = 0.23, p < .001, 95\% CI [0.12 0.35]$), somatomotor ($r = 0.33, p < .001, 95\% CI [0.22 0.44]$), dorsal attention ($r = 0.22, p = .002, 95\% CI [0.10 0.33]$), salience ($r = 0.30, p < .001, 95\% CI [0.18 0.42]$), limbic ($r = 0.26, p = .001, 95\% CI [0.14 0.38]$), and default mode ($r = 0.24, p = .002, 95\% CI [0.12 0.36]$) networks. However, no such effect was observed for the frontoparietal control network after correcting for multiple comparisons ($r = 0.21, p = .010, 95\% CI [0.12 0.36]$). The whole brain exploratory analysis found that both the somatomotor and salience networks showed the largest extents of significant vertices. **Conclusion:** These findings indicate the beneficial associations between aerobic fitness and brain health in an aging population. Cortical thickness was associated with AF across 6 of the 7 major functional connectivity networks investigated. In addition, exploratory analyses revealed that the somatomotor and salience networks had the largest extent of significant vertices. As the world's population is aging, aerobic fitness may provide a lifestyle benefit to brain health. Supported by NIA Grant R37 AG025667.

Expression Of Tyrosine Hydroxylase In The Nucleus Accumbens Are Not Altered By Diet Or Fecal Transplantation In Male C57bl/6j Mice

Brianne M. Breidenbach, Ayland C. Letsinger, Jorge Z. Granados, Tatiana N. Castro Padovani, Edward C. Nagel, J Timothy Lightfoot, FACS. *Texas A&M University, College Station, TX.* (Sponsor: J. Timothy Lightfoot, FACS)
(No relevant relationships reported)

Multiple studies have indicated that regulation of physical activity may be largely controlled by central neural factors, such as dopamine (DA) signaling in the nucleus

accumbens (NAc). It was hypothesized that metabolites produced from the gut microbiome influence DA signaling by altering the rate-limiting enzyme tyrosine hydroxylase (TH). **PURPOSE:** To determine whether microbial transplants from high active C57Bl/6J male mice eating a chow diet (CH) altered TH expression in the NAc of C57Bl/6J male mice made low active through intake of a high fat high sugar (HF) diet. **METHODS:** Mice were randomly assigned to one of four groups: a chow diet (CH/CH), a high fat to chow diet plus a microbial transplant (HF/CH+), a high fat diet to chow diet (HF/CH), or a high fat diet plus a microbial transplant (HF/HF+). Changes to group base diets and microbial transplants began at week 14. Transplants were completed once a week using sample donated from the CH/CH group via oral gavage. Mice were sacrificed at the end of 17 weeks, the NAc was dissected on ice, and flash frozen in liquid nitrogen. Immunoblotting was performed using NAc lysate probed with TH antibody. Bands were normalized using β -actin and an analysis of variance was conducted. **RESULTS:** There were no significant differences between group means for CH/CH (1.023 ± 0.59), HF/CH+ (0.8810 ± 0.21), HF/CH (0.882 ± 0.27), or HF/HF+ (1.069 ± 0.32) as determined by a one-way ANOVA, ($p = 0.51$). **CONCLUSION:** TH expression in the NAc was not altered by diet or microbial transplantation from the active CH/CH group. Funding for this study was provided by the Omar Smith Endowment at Texas A&M University.

The Relationship Between Patient Expectations And Outcomes Of Injections For Knee Osteoarthritis

Andrew George¹, Shirali Shah², Jackie Spangenberg², Joanna Barroso², Prakash Jayabalan². ¹Northwestern Feinberg School of Medicine, Chicago, IL. ²Shirley Ryan Ability Lab, Chicago, IL.
(No relevant relationships reported)

The Relationship Between Patient Expectations and Outcomes of Injections for Knee Osteoarthritis

Purpose: Patient expectations have been shown to be related to outcomes after surgery. The relationship between expectations and outcomes after less invasive treatments, such as injections for knee osteoarthritis (OA), has not been studied. The objective of this prospective study was to assess the relationship between expectations and outcome of injections for knee OA.

Methods: We measured knee injection (intra-articular steroid or hyaluronic acid) expectations using a modified version of the Knee Replacement Expectations Scale (KRES) and Roland-Morris Disability Questionnaire. Patients were re-evaluated at 4 weeks post-injection for pain and disability outcomes. A multiple regression linear analysis was applied to model expectation entry scores; association between change in outcomes and expectation scores were studied through linear regression models, controlling for baseline scores as covariates.

Results: Forty-nine ($n = 49$) knee OA patients completed the study with improvement in knee weakness being the highest symptomatic improvement expected (mean score 4.8/5). Patients had the lowest expectations of pain relief and ability to walk (mean 1.3 and 1.1/5). Multivariate linear regression modeling did not show an association between demographic/clinical variables and global expectation scores. Injection treatment did significantly reduce pain (mean pain reduction 2.3, $p < 0.001$, and disability ($p < 0.001$)). Baseline expectation score had a low but significant association with change in pain and disability (NPRS $R^2 = 0.1$, $p = 0.056$ and $R^2 = 0.14$, $p = 0.02$).

Conclusion: Knee injections improved pain and disability in this cohort of patients, and expectations before treatment had a small but significant association with patient reported outcomes. Studying a larger number of subjects and incorporating physical and psychological outcomes may further advance knowledge in this area.

Effects Of Mental Fatigue On Maximal Exercise Test Performance In Physically Active And Sedentary Adults

Nien Xiang Tou, Govindasamy Balasekaran, FACSM, Tiago Manuel Barbosa. Nanyang Technological University, Singapore, Singapore.
Email: nie17toun7250@e.ntu.edu.sg
(No relevant relationships reported)

PURPOSE: This study examined the effects of mental fatigue on maximal treadmill walking exercise performance.

METHODS: 50 young male ($n = 25$) and female ($n = 25$) adults were recruited to perform a maximal treadmill walking exercise test to volitional exhaustion on two

occasions. Prior to the exercise test, participants performed a cognitive task in a randomized, counterbalanced manner for 30 minutes, with the incongruent Stroop task in the mental fatigue condition, and leisure magazine reading in the control condition. Subjective ratings of perceived mood, fatigue, and motivation to exercise were assessed before and after the cognitive task. Perceptual and physiological responses were collected throughout the exercise test.

RESULTS: Significant decrease in perceived mood ($p < 0.001$) and motivation ($p = 0.001$), and significant increase in fatigue ($p = 0.028$) were found in the mental fatigue condition. Participants were found to rate their perceived physical exertion higher during the exercise test in the mental fatigue condition ($p = 0.042$). However, there were no significant differences in physiological responses and test exhaustion time. **CONCLUSIONS:** Mental fatigue increased perceived physical exertion during maximal treadmill walking exercise but did not impair exercise performance in both active and sedentary adults.

Effects Of Self-selected Or Experimenter-selected Music On Psychological Responses During A Sprint Interval Training Session

Marcelo Marques, Valéria Panissa, Victor Staibano, Emerson Franchini. University of São Paulo, São Paulo, Brazil.
Email: marcelomarques@usp.br
(No relevant relationships reported)

Music is widely used as an ergogenic aid before and during exercise to enhance performance. The ergogenic effects of music seem to be influenced by its choice and exercise intensity. However, little is known concerning its effects during sprint interval training (SIT). **PURPOSE:** The purpose of this study was to analyze the effects of self-selected and experimenter-selected music on perceptual (affective responses, perceived exertion, attentional focus, and enjoyment), and performance (power output) during a SIT protocol compared to a control condition. **METHODS:** 14 active males (27.0 ± 3.9 years; 79.0 ± 9.1 kg; 176.4 ± 5.3 cm) performed SIT sessions composed by 8 x 15s all-out bouts against a fixed load of 9% of body mass interspersed by 120s of passive recovery under three conditions: self-selected music (playlist of high-tempo subject's favorite music), experimenter-selected music ("Power Workout" playlist from an online streaming music platform) and no-music (control). Affective responses, perceived exertion, and power output were measured throughout the protocols. Enjoyment and attentional focus (effort and recovery) were measured after each exercise session. **RESULTS:** Perceived exertion did not differ between conditions, but a main effect of time was detected ($F_{2,26} = 1.67$; $p = 0.208$; $\eta_p^2 = 0.114$), with lower values in the first bout when compared to all others moments ($p < 0.001$). The affective responses differed between conditions ($F_{2,26} = 4.02$; $p = 0.030$; $\eta_p^2 = 0.236$), but the post-hoc indicated only a tendency ($p = 0.067$) of lower values for the self-selected music (1.3 ± 1.3 a.u.) compared to experimenter-selected music (2.0 ± 1.2 a.u.). Attentional focus also differed between conditions ($F_{2,26} = 6.62$; $p = 0.005$; $\eta_p^2 = 0.337$), however, just between self-selected (70.2 ± 30.3 a.u.) and no-music conditions (42.9 ± 27.1 a.u. $p = 0.043$). Enjoyment and power output measures did not differ between conditions, however, a main effect of time was observed for peak power ($F_{2,26} = 0.96$; $p = 0.393$; $\eta_p^2 = 0.069$), and mean power ($F_{2,26} = 1.23$; $p = 0.307$; $\eta_p^2 = 0.087$), throughout the bouts ($p < 0.001$). **CONCLUSIONS:** Although there were no significant differences between conditions concerning performance, perceived exertion, and enjoyment, listen to the self-selected music during the SIT session increased the attentional focus.

²University of Wisconsin-La Crosse, La Crosse, WI.
Email: andrea.fusco@unicas.it
(No relevant relationships reported)

Studies have shown that the ratio of blood lactate concentration to Rating of Perceived Exertion (HLA/RPE) and session RPE (sRPE) may be considered useful to detect overreaching and accumulated fatigue. However, no study has investigated their relationship. **PURPOSE:** To examine the relationship between HLA/RPE and sRPE during a period of intensified training. **METHODS:** Twelve young adults performed incremental exercise to assess their max power output (MPO). They performed 30 and 60-min interval workouts on a cycle ergometer over a 2-week period. Each session started with a 5-min warm-up at 25% MPO followed by 5-min at 50% MPO, 2-min at 25% MPO, 5-min at 75% MPO, 2-min at 25% MPO, 2-min at 100% MPO, 2-min at 25% MPO and 7-min at 50% MPO, which finished the 30-min session. During the first week, 4 sessions consisting of 30-min on Monday, Tuesday, Wednesday and a 60-min (30-min session back to back) on Thursday, were organized. After 3 days off,

the second week consisted of 3 consecutive 60-min sessions (Monday to Wednesday) with the last day (Thursday) being of 30-min. HLa and RPE were measured at the end of each stage of the interval training, and HLa/RPE computed for each session. sRPE was obtained after the sessions. Non-linear regression analysis was used to assess the relationship between HLa/RPE and sRPE. **RESULTS:** A very large negative relationship ($r = -0.70$, Root-mean-squared error = 0.59, $p < 0.0001$) was found (Figure 1). **CONCLUSIONS:** The negative relationship supports the concept that sRPE is a sensitive tool that, in addition to information about relative exercise intensity, might provide further information on accumulated fatigue. Coaches and exercise scientists without access to HLa measurement may gain insight into accumulated fatigue during periods of increased training by using sRPE.

Figure 1. Relationship between HLa/RPE and sRPE

Black dots represent all subjects' training session; black line represents the predicted mean; the grey shade area represents the 95% confidence interval of the predicted mean.

Association Between Perceived Recovery And Heart Rate In A Submaximal And Maximal Task In Firefighters

Carly A. Wahl¹, Rudi A. Marciniak¹, Cody S. Tesch², Barbara B. Meyer¹, Kyle T. Ebersole¹. ¹University of Wisconsin-Milwaukee, Milwaukee, WI. ²City of Milwaukee Fire Department, Milwaukee, WI.

Email: cwahl@uwm.edu

(No relevant relationships reported)

The job of a firefighter is physically and mentally demanding and requires maximal or near maximal effort. As time on a shift progresses, these tasks may be performed in an under recovered state due to stressors of the work. Prior research in athletes has explored the relationship between subjective measures of stress/recovery and performance on exercise tests. As such, it is possible that a firefighter's subjective assessment of recovery may influence objective measures of performance on an exercise test. **PURPOSE:** To determine the association between perceptions of recovery and heart rate (HR) response in both a submaximal and maximal task in firefighters. **METHODS:** 16 (14 male, 2 female) active-duty firefighters (35.3 ± 8.0 years, 179.1 ± 6.2 cm, 91.1 ± 16.9 kg) volunteered to participate. Participants completed a submaximal Queens College Step Test (SUBMAX) and a maximal treadmill test (MAX) with 24-72 hours separating each test. Prior to testing, participants stated their perceived recovery status (PRS; 0-10 scalar measure) to assess current state of recovery. Upon completion of each test, participants reported a rating of perceived exertion (RPE). HR was recorded at the conclusion of each test (HR_{PEAK}) and after 60 seconds of seated recovery (HR_{60}). Bivariate Pearson correlations determined the relationship between PRS, RPE, HR_{PEAK} , and HR_{60} on both SUBMAX and MAX tests. An alpha of 0.05 determined statistical significance. **RESULTS:** Significant correlations were identified in the SUBMAX test between HR_{PEAK} (137.5 ± 12.7 bpm) and RPE (10.8 ± 1.8) ($r = 0.707$, $P = 0.002$), and HR_{60} (95.4 ± 18.8 bpm) and RPE ($r = 0.619$, $P = 0.011$), but neither were related to PRS (6.8 ± 2.4). On the MAX test, HR_{PEAK} (183.0 ± 9.7 bpm) and HR_{60} (147.4 ± 13.7 bpm) were not related to either RPE (18.2 ± 1.1) or PRS (6.0 ± 2.1). **CONCLUSION:** These results suggest that among firefighters, PRS may not be a meaningful instrument to understand readiness for performance, regardless of task intensity. In addition, the task specific response for RPE may suggest self-reporting of effort is not an effective method to evaluate intensities greater than a submaximal level. Firefighter-specific measures should be developed to better determine subjective recovery and effort to guide implementation strategies with which to optimize health and performance readiness.

2331 Board #250 May 28 2:00 PM - 3:30 PM
Reducing Sedentary Time In Fibromyalgia (ReSeT-FM): A Feasibility Study

Eric Evans. Indiana University - Purdue University Indianapolis, Indianapolis, IN.

(No relevant relationships reported)

Fibromyalgia (FM) is characterized by chronic widespread musculoskeletal pain, impaired functional mobility and extreme sedentary behavior (SB). Research suggests that individuals with FM who spend more time in SB experience greater clinical pain and overall impact of FM, irrespective of time spent in moderate to vigorous physical activity (PA). To date, no studies have investigated the potential impact of reducing SB on key clinical outcomes in FM. **PURPOSE:** To evaluate the feasibility of an 8-week behavioral intervention designed to replace SB with light PA in Veterans with FM. **METHODS:** Nine veterans with FM completed an 8-week intervention designed to reduce sedentary time, which included: 1) Education on the risks of being sedentary, 2) Wearing an activity tracker that provided behavioral prompts to move during prolonged sedentary behavior and synched with a phone app to self-monitor activity and stationary time, 3) Weekly 30-minute meetings with a study coach to set and review progress towards goals aimed at reducing time in SB. PA levels (Sedentary, High and Low light PA, High and Low moderate PA) were objectively measured at baseline and during the last week of the intervention with accelerometers worn for 1-week at each assessment. Participants also completed the Fibromyalgia Impact Questionnaire-Revised (FIQR) and Brief Pain Inventory pre and post intervention. **RESULTS:** While the results trended in the right direction, the paired t-tests indicated no significant differences between pre and post sedentary levels ($p = .23$), low light PA ($p = .32$), high light PA ($p = .12$), low moderate PA ($p = .18$) and high moderate PA ($p = .89$). Pain severity ($p = .022$), pain interference ($p = .002$), and total FIQR score ($p = .035$) significantly decreased from pre to posttest. Bivariate correlations indicated that greater increases in high light PA were associated with greater reductions in pain severity ($r = -.750$, $p = .020$) and total FIQR score ($r = -.803$, $p = .009$). **CONCLUSION:** While the intervention did not significantly decrease sedentary time or increase light PA in veterans with FM, these results suggest that increasing light PA in FM patients could potentially have a positive impact on pain outcomes. This study was funded by the School of Health and Human Sciences at IUPUI.

Impact Of Mental Fatigue In Endurance Sports Performance

Romeu Candido, Jr, João Pedro de Almeida, Domingos R. Pandelo, Jr. CAP, Santos, Brazil.

Email: romeuj7@gmail.com

(No relevant relationships reported)

PURPOSE: The aim of the present study is to evaluate the effect on the overall perception of well being (OPWB) in the sports performance, as measured by an incremental treadmill running test, in mentally fatigued volunteers. **METHODS:** 34 volunteers participated in the study, 18 males and 16 females. They were divided into 2 groups and each volunteer performed 2 incremental treadmill running tests (2 minutes stage) in different dates. The tests were interrupted at the request of the volunteer. After the first test, the volunteers were randomly divided into 2 groups of 17 individuals each. One of the groups was driven to a mental fatigue by taken a mathematics test, 30 minutes before the test. The second group (control group), was led to mental fatigue. The mental fatigue group filled a questionnaire immediately after the test, to check the impact of the mathematics test on the OPWB. The OPWB questionnaire presented 5 possible classifications (1 very bad, 2 reasonable, 3 good, 4 very good, 5 excellent). The treadmill running tests were performed 72 hours apart. **RESULTS:** From the group that was driven to fatigue (17 volunteers), 9 were female and 8 males. 44% of the females had no change in the OPWB score, as did 37.5% of the males. Therefore, in this study, males were more susceptible to mental fatigue after performing the mathematics test. By taking an average of the scores, before and after the mathematics test, the overall score went from 3.94 to 3.12 (4.00 to 3.22 for females and 3.88 to 3.00 for males). In other words, a reasonable reduction in OPWB was observed in volunteers undergoing the mathematics test, which indicates that they were fatigued. Another interesting aspect was to evaluate the impact of the worsening in OPWB on the performance of the volunteers. In the group not led to mental fatigue (control group), there was a positive variation of 12% between the first and the second test. However, in the group driven to mental fatigue there was a reduction of 11.82% in their performance (same was measured taken in consideration the duration of the test), being 12.26% for the male volunteers and 11.45% for females. **CONCLUSIONS:** The present study showed that mental fatigue seems to impact sports performance. Therefore, searching for training strategies to support greater mental fatigue seems to be relevant.

Three Weeks Of Mental Strength Training Improves Cycling Performance By Changing Key Physiological Parameters

Gavin E. Hoiosen¹, Michael C. Oldach¹, Sten H. Kajitani¹, Emma Gabriano¹, Stephen P. Gonzalez², Timothy A. VanHaitsma¹. ¹Westmont College, Santa Barbara, CA. ²Dartmouth College, Hanover, NH.
 Email: tvanhaitsma@westmont.edu
 (No relevant relationships reported)

Short-term grit and resilience training, as well as internal self-talk training have increased physical performance. However, little is known about longer mental training. **PURPOSE:** Perform 21 days of mental training to observe how performance and physiological variables change.

METHODS: Participants were 33 college-aged (16 mental strength (MS), 17 control (CON)) individuals (20.7 ± 1.2yrs, weight 72.3 ± 9.3kg, height 1.77 ± .09m, VO_{2peak} 47.9 ± 9.3mL/kg/min). A VO_{2peak} was performed on a cycle ergometer on day one. Subsequent visits consisted of time trials to exhaustion (TTE) performed 10% above ventilatory threshold. MS groups watched one of four 10-minute videos daily for 21 days. VO₂, ventilation (VE), respiratory rate (RR), tidal volume (TV), heart rate (HR), RPE, and VAS scores (0-100) for pain and fatigue were recorded during pre- and post-time trials. Participants took GRIT-S and CD-Rise psychological surveys before pre- and post-TTE. RM-ANOVA were done to compare group, time, and trial differences as a percentage of total time as well as absolute times (0-3 minutes).

RESULTS: TTE significantly increased for MS (8.8 ± 13.2%) and decreased for CON (-6.6 ± 14.6%, p < 0.05). VO₂, VE, RPE, fatigue, and pain as a percentage of total time were unchanged. HR was significantly higher after 21 days of MS compared to CON at 40, 60, 80, and 100% of TTE (p < 0.05). When compared at absolute times, there were significant decreases in VO₂ at minute 3 (p < 0.05) and VE at minute 2 and 2.5 (p < 0.05). RR was lower following MS (p < 0.05) though there was no difference in TV. There was a trial x group interaction in RPE (F(1,25) = 4.823, p < 0.05) with MS experiencing a decrease in RPE after training.

CONCLUSION: MS training for three weeks allowed participants to cycle longer before exhaustion. HR increased as a percentage of TT time post-MS training, perhaps due to increased duration post-TTE leading to measuring HR at later absolute times. By measuring HR later, metabolites would be expected to be higher, thus increasing HR. Decreases in VE and RR may be due to one of the mental strategies that involved instruction to reduce stress and anxiety by taking deeper and slower breaths, which may contribute to a reduced perception of effort. Finally, MS training reduced O₂ consumption, contributing to a decreased RPE and increased TTE duration.

The Effects Of Essential Oils On Perception Of Exertion, Task Pleasantness And Time On Task

Selen Razon¹, Katelyn Koser¹, Umrit Tokac², Melissa Whidden, FACSM¹, Melissa Reed¹, Meghan Ramick¹. ¹West Chester University, West Chester, PA. ²University of Missouri, Saint Louis, MO. (Sponsor: Melissa Whidden, FACSM)
 (No relevant relationships reported)

Essential oils have become wildly popular in recent years for their therapeutical and health-related benefits. Research that focuses on essential oils and their ergogenic effects may be helpful in increasing adherence to exercise by making the task more pleasant and/or less exertive (Basevitch, 2011; Jaradat et al, 2016). **PURPOSE:** The purpose of this study was to test the effects of essential oils on perception of exertion, exercise task pleasantness and total time on task. **METHODS:** Thirty college students (24 females, 6 males) were recruited to perform a handgrip squeezing task. They were randomly assigned to one of three groups: placebo, bergamot essential oil, or peppermint essential oil (n_{Peppermint} = 10, n_{Placebo} = 10, n_{Bergamot} = 10). Adhesive strips with each essential oil were placed under the noses of all participants. Participants in the placebo group had a strip with no essential oil. After establishing participants' baselines for maximal voluntary contraction, participants squeezed a handgrip dynamometer at 30% of their baseline for as long as they could tolerate. Participants' session RPE, perceived exercise-task pleasantness and total grip time were recorded at session completion. **RESULTS:** Results from ANOVA analysis showed no significant group effect for RPE session (p > .05). Chi square analyses indicated that participants in the placebo group rated the exercise task most pleasant, (n=6, Pleasant). Participants with bergamot essential oil rated the task as mildly pleasant, (n=5, Mildly Pleasant). Participants with peppermint essential oil rated the task as least pleasant (n=6, Neutral) and these differences were significant (p < .05). Due to small size in each group and the skewness of the distribution, group medians were also analyzed as more robust and sensible signs of central tendency. Results indicated that participants with bergamot essential oil squeezed the dynamometer longer durations than others with peppermint essential oil or placebo (M_{Bergamot} = 18.07 minutes; M_{Placebo} = 15.31 minutes;

and M_{Peppermint} = 12.27 minutes). **CONCLUSION:** These findings suggest that bergamot essential oil may help optimize exercise-related affects and increase exercise duration. Studies with larger sample sizes are needed to confirm these findings.

Effects Of Transcranial Direct Current Stimulation During Aerobic Exercise On Cognition, Perceived Exertion And Cycling Performance

Fabian Thomas¹, Alisa Berger¹, Nils Pixa², Ming-Yang Cheng³, Michael Doppelmayr⁴, Fabian Steinberg⁵. ¹Institute of Sport Science, Mainz, Germany. ²Institute of Human Movement Science and Health, Chemnitz, Germany. ³Rheinische Friedrich Wilhelms University, Bonn, Germany. ⁴Institute for Sport Science, Mainz, Germany. ⁵Louisiana State University, Baton Rouge, LA.

(No relevant relationships reported)

PURPOSE: Interest in harmless but effective and easy-to-use methods such as transcranial direct current stimulation (tDCS) and aerobic exercise (AE) to improve cognitive performance in health and disease is growing. Recent research suggests that a combined application of both methods in a multimodal manner (e.g. tDCS before, during or after AE) could lead to improved cognitive improvement. Also tDCS could be a potential tool to modulate sports performance parameters such as perceived exertion and endurance capacity. Thus, here we investigated the impact of tDCS during moderate AE (cycling) on cognition, perceived exertion and power output. **METHODS:** Data from 101 healthy subjects (average age = 25.31, SD = 2.05, female = 45) were collected in five separate experiments (EXP). Each experiment had a crossover design. EXP-1: anodal tDCS vs. sham during active control (AC); EXP-2: cathodal tDCS vs. sham during AC; EXP-3: AE vs. AC; EXP-4: a. tDCS vs. sham during AE; EXP-5: c. tDCS vs. sham during AE. High-resolution (HD-)tDCS was applied for 25 minutes at 1 mA to the left dorsolateral prefrontal cortex (DLPFC) using a 4x1 ring electrode configuration (stim electrode at F3). For AE, subjects ran at 75% of their maximum heart rate (moderate intensity) for 25 minutes, while rating of perceived exertion (RPE) and power output (watts) were recorded every four minutes. As a measure of cognition, response inhibition was assessed before and after 20 minutes during the ongoing intervention by a flanker task. **RESULTS:** A relevant TIME x CONDITION interaction for cognitive performance was only found in EXP-5. Cathodal tDCS during cycling led to a decrease in accuracy whereas accuracy remained constant for sham tDCS during cycling, F(1,23) = 4.58, p = .043, η_p² = .17. A sig. TIME x CONDITION x SEX showed that men were better able to maintain their cycling performance (measured in watts) during the intervention if when receiving anodal tDCS, F(2,32,44.03) = 3.27, p = .041, η_p² = .15. No interaction effects could be demonstrated for RPE and heart rate. **CONCLUSIONS:** Contrary to current literature only the multimodal, but not unimodal application of tDCS and AE had an influence on cognitive performance. The application of anodal tDCS during moderate AE led to improved cycling performance in men, a finding requiring further consideration in the future.

 (No relevant relationships reported)

Sleep restriction is a prevalent operational stressor that may degrade neurophysiological performance in military personnel. Transcranial magnetic stimulation (TMS) is an established non-invasive brain stimulation technique capable of assessing corticospinal excitability that is not extensively investigated in military populations. **PURPOSE:** To examine the influence of operational stress (i.e., sleep restriction) on corticospinal excitability in military personnel. **METHODS:** Thirty-one male and seven female service members (25.1 ± 4.9yr) performed two series of stimulus response curves (SRCs) at 15% maximum voluntary muscle contraction for five consecutive days (D0-D4) using single-pulse TMS and a figure-of-eight coil. A familiarization day served as D0 with baseline testing on D1. Participants were allowed eight hours to sleep on D0, D1 and D4. On D2 and D3, participants had their sleep restricted for two 2-hour segments. For the SRC, stimulator outputs were randomly administered from 5-100% in 5% increments. Motor evoked potentials of the first dorsal interosseous muscle were quantified as the peak-to-peak electromyography amplitude of the 50ms post TMS stimulus. Corticospinal excitability was assessed by fitting MEP responses to a Boltzmann sigmoidal curve (BSC) via nonlinear regression and determining BSC_{MAX} and BSC_{V50} (i.e., stimulator output at the mid-point between

BSC_{MIN} and BSC_{MAX}). Repeated-measures one-way ANOVAs with Tukey post-hoc tests were used to compare BSC properties over time. **RESULTS:** ANOVAs revealed a main effect of time for both BSC_{MAX} and BSC_{V50} ($F(3.31, 122.40)=2.71, p=.04$ and $F(2.96, 109.50)=3.26, p=.02$, respectively). No significant pairwise comparisons were detected for BSC_{V50}. BSC_{MAX} revealed to be significantly greater on D3 compared to D0 (5.21 vs 4.56 mV, $p=.02$) and D1 (5.21 vs 4.44 mV, $p=.02$) but similar to D2 and D4 ($p>.05$). **CONCLUSION:** Our findings suggest corticospinal excitability is a sensitive biomarker for subtle alterations during simulated operational stress. Furthermore, BSC_{MAX} remained elevated on D4, suggesting one day is inadequate recovery time after operational stress. Supported by the Department of Defense W81XWH-16-PHTBIRP-CR3A.

The Effect Of Moderate-intensity Intermittent Interval Walking On Heart Rate And Enjoyment In Middle-aged Women

Curtis Fennell¹, Jermaine Mitchell¹, Kayla E. Chambers².
¹University of Montevallo, Montevallo, AL. ²University of Alabama at Birmingham, Birmingham, AL.
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to investigate heart rate (HR) and exercise enjoyment during and following three walking protocols in middle-aged women. **METHODS:** Ten women (mean \pm SD = 55 \pm 4 years) completed three walking protocols of the same work volume (90 MET-min) in a randomized, counter-balanced order. The protocols consisted of one 30-min bout of low-moderate continuous walking (CW) (3 METs; ~ 4.8 km/h), three 10-min bouts of low-moderate intermittent walking (IW), and three 8-min 40-s bouts of intermittent interval walking (IIW) with cycles of 30 s:120 s of high-moderate (5 METs; ~ 6.4 km/h): low-moderate intensities. HR and exercise enjoyment were assessed during six evenly distributed exercise increments and post-exercise (0-min, 10-min). The Exercise Enjoyment Scale (EES) was utilized to assess enjoyment during and post-exercise, while the Physical Activity Enjoyment Scale (PACES) only assessed post-exercise enjoyment. Repeated measures ANOVA was used to analyze mean HR and enjoyment differences between experimental treatments. **RESULTS:** IIW (112.0 \pm 16.0) elicited a significantly higher during exercise HR than IW (105.0 \pm 14.0; $p = 0.01$), but HR during CW (107.0 \pm 14.0; $p > 0.05$) was not different from the other treatments. Immediately following exercise (0-min), both CW (108.0 \pm 14.0; $p = 0.004$) and IIW (109.0 \pm 16.0; $p = 0.03$) elicited a significantly higher HR than IW (102.0 \pm 14.0). However, 10 min later, CW (82.0 \pm 18.0) elicited a significantly higher HR than IW (73.0 \pm 12.0); IIW (77.0 \pm 13.0; $p > 0.05$) did not differ from the other treatments. Despite during and post-exercise HR differences, exercise enjoyment during (CW: 4.0 \pm 0.82; IW: 4.0 \pm 0.61; IIW: 4.0 \pm 1.2) and following (EES 0-min: CW: 4.0 \pm 0.99; IW: 4.0 \pm 0.68; IIW: 4.0 \pm 1.4) (PACES 0-min: CW: 89.0 \pm 10.1; IW: 89.0 \pm 11.5; IIW: 88.0 \pm 22.4) (EES 10-min: CW: 4.0 \pm 1.1; IW: 4.0 \pm 0.66; IIW: 4.0 \pm 1.2) (PACES 10-min: CW: 89.0 \pm 15.0; IW: 88.0 \pm 12.6; IIW: 86.0 \pm 20.2) exercise were not different amongst treatments (all $p > 0.05$). **CONCLUSION:** Based on the results of the present study, it is possible to conclude that moderate-intensity intermittent interval walking may be a viable exercise prescription suitable for middle-aged women to progress to higher exercise intensities and address the barrier of time.

2338 Board #257 May 28 2:00 PM - 3:30 PM
Perceptions Of Pain Over A 4-week Neuromuscular Electrical Stimulation Treatment In Older Adults

Monica A. Mendoza, Samantha J. Goldenstein, Shelby L. Summers, Derek Moczygema, Lindsay E. Kipp, Joni A. Mettler. *Texas State University, San Marcos, TX.* (Sponsor: Tinker Murray, FACSM)
 (No relevant relationships reported)

Neuromuscular electrical stimulation (NMES) evokes involuntary muscle contraction and may be a safe and effective treatment option for muscle strengthening. However, little research exists on patient tolerance to NMES in older adults. **PURPOSE:** The aim of this study was to determine changes in stimulation intensity and perceived pain pre-post 4 weeks of NMES training in older adults. **METHODS:** Participants ($n = 9$) were healthy, older adults (69.9 \pm 2.4 years). Subjects performed maximal voluntary contractions (MVC) of the quadriceps muscles on an isokinetic dynamometer to determine maximal strength. Participants were seated in the isokinetic dynamometer with the knee at 60° and a 40-min NMES treatment was applied to the quadriceps muscles of each leg 3 times per week for 4 weeks. Stimulation frequency was 60 Hz with repeated cycles of 10s on and 15s off. Stimulation intensity was set to achieve 15% MVC and was increased every 5 minutes if the torque dropped below 15% MVC. Using a standard pain scale, participants were asked to rate perceived pain (0 = no pain, 10 = worst pain possible) during the NMES at 1, 20, and 40 minutes of stimulation on each leg during treatment day 1, 7, and 12. Stimulation intensity was also recorded. Pain scores and stimulation intensity were averaged across right and left leg. Pain score and stimulation intensity were each analyzed with a 3 x 3

repeated measures analysis of variance (DAY x MIN), with significance set at $p \leq 0.05$. **RESULTS:** For perceived pain, there was a significant main effect for MIN ($p = 0.011$) and DAY ($p = 0.004$). For MIN, perceived pain significantly increased (MIN 1: 3.2 \pm 0.8 vs MIN 20: 4.5 \pm 0.7; $p = 0.009$) and then remained stable (MIN 40: 5.2 \pm 0.8; $p = 0.052$). For DAY, perceived pain decreased 36.2% (DAY 1: 5.8 \pm 0.8 vs DAY 7: 3.7 \pm 0.7; $p = 0.001$) and then remained stable (DAY 12: 3.4 \pm 0.9; $p = 0.488$). For stimulation intensity, there was a significant main effect for DAY ($p = 0.001$). Stimulation intensity for DAY increased (DAY 1: 13.3 \pm 0.9 vs DAY 7: 16.3 \pm 1.5 mA; $p = 0.003$) and then decreased (Day 12: 14.8 \pm 1.3 mA; $p = 0.012$). **CONCLUSION:** Findings indicate that participants experienced moderate discomfort during the first NMES treatment. However, perceived pain decreased significantly by day 7, demonstrating that NMES may be a feasible muscle strengthening option for older adults.

2339 Board #258 May 28 2:00 PM - 3:30 PM
No Sex Differences In Conditioned Pain Modulation Or Exercise-induced Hypoalgesia Following Lower Body Isometric Exercise

Robert E. Hight, Jessica A. Peterson, Cameron Lohman, Michael G. Bembem, FACSM, Rebecca D. Larson, Christopher D. Black, FACSM. *University of Oklahoma, Norman, OK.*
 (No relevant relationships reported)

Women are more at risk than men for developing chronic pain conditions. Differences in endogenous pain-modulatory function could be a contributing factor. **PURPOSE:** The aim of this study was to compare conditioned pain modulation (CPM) and exercise-induced hypoalgesia (EIH) responses between adult men and women. **METHODS:** In a cross-sectional, non-randomized study with two independent groups of college aged males ($n = 52$) and females ($n = 45$), pressure pain thresholds (PPT) were assessed bilaterally in the vastus lateralis (VL) and brachioradialis (BR) muscles using a pressure algometer prior to and immediately following a conditioning stimulus (placing their foot in an ice bath) and performing isometric knee extension exercise to failure at 25% of maximal strength. **RESULTS:** Men had higher baseline PPTs than females (LBR: 372 \pm 217 vs. 303 \pm 119; RBR: 396 \pm 236 vs. 315 \pm 143; NDVL: 552 \pm 281 vs. 434 \pm 157 DVL: 572 \pm 253 vs. 454 \pm 147; $P < 0.01$). PPTs increased significantly ($P < 0.05$) following the conditioning stimulus in both males and females (LBR: 387 \pm 264 to 453 \pm 318 kPa, and 315 \pm 126 to 359 \pm 145 kPa; RBR: 400 \pm 225 to 450 \pm 280 kPa; and 325 \pm 135 to 372 \pm 161 kPa; DVL: 579 \pm 289 to 658 \pm 349 kPa; and 470 \pm 200 to 541 \pm 201 kPa; NDVL 542 \pm 263 to 623 \pm 326 kPa; and 433 \pm 174 to 503 \pm 185 kPa in the males and females, respectively) indicating a CPM response in all limbs tested. PPTs increased significantly ($P < 0.05$) following isometric knee extension exercise to a similar extent in both males and females in all limbs tested (LBR: 387 \pm 177 to 466 \pm 245 kPa; and 305 \pm 140 to 353 \pm 162 kPa; RBR: 409 \pm 172 to 462 \pm 228 kPa; and 312 \pm 147 to 355 \pm 173 kPa. DVL: 572 \pm 253 to 763 \pm 366 kPa; and 454 \pm 147 to 611 \pm 252 kPa; NDVL: 552 \pm 281 to 633 \pm 353 kPa and 434 \pm 157 to 526 \pm 210 kPa) There was no interaction between the group x testing site for either the CPM response ($P = 0.314$) or the EIH response ($P = 0.242$). **CONCLUSIONS:** Men had a higher resting pain threshold than women. However, men and women exhibited similar endogenous pain inhibitory function both locally and systemically following a conditioning stimulus and isometric lower body exercise.

Concurrent Pain Effects On Exercise Tolerance, Neuromuscular Fatigue And Perceptual Responses, Preliminary Data.

Delbar Jazayeri, Sam Yeung, Rojan Khoshreza, Rafael A. Azevedo, Saied Jalal Aboodarda. *University of Calgary, Calgary, AB, Canada.*
 Email: delbar.jazayeri@ucalgary.ca
 (No relevant relationships reported)

Exercise-induced fatigue and pain negatively affect exercise tolerance; however, the influence of these sensations on regulation of neuromuscular (NM) and perceptual responses during locomotor exercise has yet to be determined. **PURPOSE:** To investigate the effects of one leg exercise-induced fatigue and pain on the contralateral leg exercise tolerance, NM and perceptual responses. **METHODS:** Nine healthy young men (age: 26 \pm 7 years) performed right leg sustained contraction at 25% of isometric maximal voluntary contraction (25%IMVC) to task failure. In three testing sessions, the 25%IMVC protocol was preceded by one of the three left leg interventions including: i) 6 min rest (CON) ii) cycling to exhaustion at 80% of peak power output (CYCL) and iii) CYCL immediately followed by blood flow occlusion to right leg task failure (OCCL). The experimental sessions were selected randomly. NM function was characterized by assessing IMVC and voluntary activation (VA) using twitch interpolated technique. Right leg pain and rating of perceived exertion (RPE) were also recorded during sustained contraction. **RESULTS:** 25%IMVC to task failure was longer in CON (221 \pm 106 s) than CYCL (141 \pm 67 s) and OCCL (119 \pm 51 s) ($p < 0.05$). Relative to baseline, the drop on IMVC was similar for CON (-40 \pm 10%), CYCL

($-36 \pm 18\%$) and OCCL ($-32 \pm 17\%$) ($p = 0.09$). VA drop was also similar for CON ($-6 \pm 12\%$), CYCL ($-9 \pm 11\%$) and OCCL ($-15 \pm 18\%$) ($p > 0.05$). The potentiated twitch force decline was lower for OCCL ($-44 \pm 25\%$) when compared to CYCL ($-53 \pm 24\%$) and CON ($-51 \pm 23\%$) ($p < 0.05$). During the 25%IMVC, RPE at the onset was lower for CON (7 ± 2) compared to CYCL (13 ± 3) and OCCL (14 ± 3) ($p < 0.001$) but no difference was observed between the three conditions at the task failure (18 ± 2 , 19 ± 1 and 19 ± 1 , respectively) ($p > 0.05$). Right leg pain increased from onset to exhaustion for CON (2 ± 2 and 9 ± 1), CYCL (2 ± 2 and 9 ± 1) and OCCL (2 ± 1 and 9 ± 1) ($p < 0.05$). Left leg pain decreased from the onset of the right leg exercise to task failure for CYCL (6 ± 1 and 3 ± 2) ($p < 0.05$) however it stayed high during OCCL (9 ± 1 and 9 ± 1) ($p < 0.05$). **CONCLUSION:** Our preliminary data suggest that one leg exercise-induced fatigue and pain decreased the contralateral leg exercise tolerance, exacerbated perceptual pain and RPE, and blunted peripheral fatigue during subsequent exercise.

Internal Load Metrics In Division III Men's And Women's Soccer: The Significance Of Sleep Quality

Andreas Stamatis¹, Grant Morgan². ¹SUNY Plattsburgh, Plattsburgh, NY. ²Baylor University, Waco, TX.
 Email: astam004@plattsburgh.edu
 (No relevant relationships reported)

Wearable technology is the number one fitness trend for 2019. Sleep quality (SQ), sleep duration, mood, stress, soreness, and fatigue have been associated with performance in sports through physiological and psychological mechanisms. Division III (DIII) schools are the biggest participant in NCAA. In terms of number of athletes, soccer is the second most popular sport in NCAA.

PURPOSE: To investigate the relationship of SQ with sleep duration, mood, stress, soreness, and fatigue in a DIII men's and women's soccer team.
METHODS: All 56 players agreed to participate ($M_{age} = 19.42$, $SD = 1.09$). Data were collected using readiness surveying based on the Titan 1+ sensor protocol. Subjective information on SQ, sleep duration, mood, stress, soreness, and fatigue was reported by each athlete before every practice and game. All data, but sleep (in hours), were quantified via a 0-10 visual analog scale (e.g., SQ: 0=Excellent, 10=Poor). In total, 200 assessments took place in pre- and in-season. The analysis consisted of Pearson correlations, t tests, and regression analysis in R .

RESULTS: The correlations of SQ with the other variables were: sleep duration ($r = -.43$), mood ($r = .70$), stress ($r = .62$), soreness ($r = .53$), and fatigue ($r = .83$). There were no statistically differences between male and female athletes on any of the variables included in the analysis. Therefore, the data were analyzed in aggregate. The regressions were estimated to examine the expected increase in these outcomes for a one-point improvement in reported SQ (e.g., a one-point improvement in SQ is associated with an expected 0.98-point improvement in reported fatigue; $p < .001$).
CONCLUSIONS: On average, the findings indicate a strong relationship between SQ and hours of sleep, mood, stress, fatigue, and soreness in this DIII soccer program. Therefore, there is preliminary evidence to support that all stakeholders may need to focus on SQ strategies (including sleep duration) as means to manipulate several internal load variables that affect performance in sports. Future studies should add external metrics (e.g., speed/sprint/impact metrics), investigate differences between practice and game-day data and Divisions, and collect information from larger samples. Possible limitations include convenience sample and self-reported data.

2342 Board #261 May 28 2:00 PM - 3:30 PM
Session RPE During A Constant Load Submaximal Treadmill Exercise

Anjali Gairola, Thariana Salazar, Ruth Georges, Kristen Betterman. Cabrini University, Radnor, PA.
 Email: ag3456@cabrini.edu
 (No relevant relationships reported)

Session-RPE (S-RPE) is a measure of perceived exertion experienced for an entire exercise session but estimated post-exercise following a prior defined period of rest (Thekkada, 2006). **PURPOSE:** To study the relationship of S-RPE with differentiated (Leg-RPE, Chest-RPE) and undifferentiated (Overall-RPE) RPE during constant load submaximal treadmill exercise. **METHODS:** A total of 18 participants (Males = 8, and Females = 10; 21.5 years \pm 2.4 years) non-athletes healthy physically active (as per ACSM guidelines) participants from Cabrini University volunteered for the study. Each subject completed a 15-minute moderate intensity constant-load treadmill exercise. During exercise, at minute 5, 10, and 15; L-RPE, C-RPE, and O-RPE were estimated using the Adult OMNI-Walk/Run Scale. The average RPE for leg (L-RPEavg), chest(C-RPEavg), and overall body (O-RPEavg) for entire exercise session was also calculated. 5-minute post-exercise S-RPE was obtained for overall body. **RESULTS:** S-RPE was significantly correlated ($r = 0.41-0.55$, $p < 0.01$) with O,L,C- RPEavg and O,L,C- RPE for 5,10, and 15 minute. The highest correlation ($r = 0.55$, $p < 0.01$) was observed between S-RPE and O- RPEavg. **CONCLUSION:** The current study shows that S-RPE was strongly related to average of entire exercise

session O-RPE. Previous literature has shown that a single session-RPE rating may accurately reflect the intensity of an exercise session (Haddad, 2017). Future studies should explore the effect of varied duration, intensity, and mode of exercise on S-RPE.

The Effects Of Mental Imagery Use On Perceived Exertion And Exercise Tolerance

Peter Greenland¹, Selen Razon¹, Umit Tokac², Gershon Tenenbaum³. ¹West Chester University, West Chester, PA. ²University of Missouri, St Louis, MO. ³Florida State University, Tallahassee, FL. (Sponsor: Melissa Whidden, FACSM)
 (No relevant relationships reported)

Physical inactivity is the main public health concern of the 21st century (Blair, 2009). Perceptions of exertion and physiological stress are important contributors to the problem of physical inactivity (Lind, Welch, & Ekkekakis, 2009). **PURPOSE:** The purpose of this study was to test the effectiveness of two types of mental imagery (associative vs. dissociative) on perceived exertion and physiological stress. **METHODS:** Forty-five college students (22 males, 23 females) were randomly assigned to dissociative imagery, associative imagery, and control (i.e., no imagery) conditions. Participants completed a progressive cycling task to volitional fatigue. Ratings of perceived exertion (RPE), attention focus and heart rate (HR) were monitored at 1minute intervals. Lactate accumulation (LA) was recorded at RPE=12 and at task completion. **RESULTS:** Participants using associative imagery reported the highest RPEs ($p < .05$). These participants also tended to tolerate the task longer as compared to both the dissociative imagery group ($ES = .04$) and the control group ($ES = .14$). Participants in the associative imagery condition focused more on internal cues of exertion ($p < .01$). Participants using either type of imagery seemed to expend increased effort as demonstrated by higher ($p = .102$) means for lactate accumulation during and at the completion of the task. **CONCLUSION:** Using associative imagery might cause individuals to focus on internal cues of exertion thus increasing the subjective perception of effort. However, using associative imagery may help increase exercise tolerance compared to dissociative imagery or no imagery. These findings are consistent with previous research and may have important implications for promoting exercise tolerance.

Exercise-induced Hypoalgesia Differ At Sites Local And Remote To The Exercising Muscle Group

Ashley M. Venturini, Jessica A. Peterson, Cameron Lohman, Michael G. Bembem, FACSM, Rebecca D. Larson, Christopher D. Black, FACSM. The University of Oklahoma, Norman, OK.
 (Sponsor: Christopher D. Black, FACSM)
 (No relevant relationships reported)

Dysfunction of endogenous pain-inhibitory function such as exercise-induced hypoalgesia (EIH) may predict development of chronic pain conditions. While EIH has been shown to occur in both the exercised muscle group and in remote unexercised muscle group, few studies have compared the magnitude of EIH in an exercised muscle and remote muscle groups in the same individuals following the same exercise bout. **PURPOSE:** The purpose of the study was to examine the EIH response at four different sites following a bout of single legged isometric exercise. **METHODS:** Pressure pain thresholds (PPT) of 102 participants (50 females; 52 males) were assessed bilaterally in the vastus lateralis (VL) and brachioradialis (BR) using a pressure algometer before and after isometric knee extension at 25% of maximal voluntary contraction held until task failure using their dominant leg. The percent difference between post and pre measures was defined the EIH response. **RESULTS:** PPT's increased in the left BR ($18.1\% \pm 24.7$; $p < 0.001$, $d = 0.275$), right BR ($14.4\% \pm 26.1$; $p < 0.001$, $d = 0.233$), non-dominant VL ($17.4\% \pm 24.0$; $p < 0.001$, $d = 0.318$) and the dominant VL ($34.5\% \pm 28.3$; $p < 0.001$, $d = 0.643$). There were no differences between the left and right BR and the non-dominant VL with regards to the EIH response ($p > 0.05$), however the exercised leg demonstrated a greater EIH response compared to the remote, unexercised limbs ($p < 0.001$). **CONCLUSION:** EIH occurred in all sites. However the EIH response in the exercised leg was significantly more robust than the remote, unexercised sites. This findings suggests the magnitude of EIH is determined by both local and systemic factors and this should be taken into consideration when comparing EIH among studies.

Relationship Between Enhanced Cognitive Function And Autonomic Nervous Activity After A Subjectively Selected Intensity Exercise
 Yukiya Tanoue¹, Takaaki Komiyama², Hiroaki Tanaka¹, Yasuki Higaki¹, Yoshinari Uehara¹. ¹Fukuoka university, Fukuoka, Japan. ²Osaka University, Osaka, Japan.
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to identify a practical method for engaging in exercise that could improve cognitive function. We tested whether cognitive function improves after exercise at subjectively selected intensity by using ratings of perceived exertion (RPE). In addition, we examined the relationship between the improvement in cognitive function and cardiac autonomic nervous system.

METHODS: Twelve participants performed cognitive tasks in a running or resting condition with a randomized crossover design. In the running condition, the participants ran on a treadmill for 10 min at the running speed correspond to the RPE10-12 for each participant. Cognitive tasks including the Spatial Delayed Response task and Go/No-Go task were performed before and after running or resting. Cardiac autonomic nervous activity was obtained by calculating from heart rate variability during cognitive tasks.

RESULTS: In the running condition, the RPE was 11.1 ± 0.8 immediately after running. Running at the RPE10-12 significantly improved reaction time in the Go trials (688 ± 191 [Pre] vs 568 ± 159 ms [Post], $P < 0.05$). In the resting condition, cognitive performance was unchanged throughout the experiment (628.5 ± 163.1 ms [Pre] vs 666.9 ± 139.7 ms [Post], $P > 0.05$). Parasympathetic nervous activity remained lower after running at RPE10-12 (586 ± 424 ms² [Pre] vs 373 ± 322 ms²), but sympathetic nervous activity was not changed. Moreover, the Δ reaction time (Post-Pre) tended to be positively correlated with Δ parasympathetic nervous activity ($r = 0.514$, $P = 0.088$). In contrast, Δ reaction time was not associated with Δ sympathetic nervous activity ($r = 0.177$, $P = 0.581$).

CONCLUSIONS: The present study demonstrated that subjectively selected intensity of exercise can improve cognitive function. The improvement in cognitive function after exercise may be associated with cardiac autonomic nervous activity.

Heart Rate And Rating Of Perceived Exertion During High-intensity Interval Training: Implications For Prescribing Intensity
 Emily R. Dunston, Alan J. Coelho, Katrina Taylor. Eastern Washington University, Cheney, WA.
 Email: emilydunston@eagles.ewu.edu
 (No relevant relationships reported)

High-intensity interval training (HIIT) is a popular and effective time-efficient alternative to moderate-intensity continuous training for improving cardiorespiratory fitness in a wide range of populations. However, there is limited research investigating the most effective and practical way to prescribe training intensities for HIIT.

PURPOSE: To determine heart rate (HR) and rating of perceived exertion (RPE) responses across a single bout of HIIT. Additionally, the relationship between HR and RPE were examined. **METHODS:** Young adults ($n=16$; age 21.8 ± 1.4 years; 10 females) visited the lab on two separate occasions. At the first visit, participants completed an incremental exercise test on a cycle ergometer to determine peak power output (PPO). Participants completed the HIIT session during their second lab visit. The HIIT protocol involved ten, 1-minute bouts of cycling at 80% PPO interspersed with 1-minute of active rest cycling at 20% PPO. HR and RPE were measured at the end of the first, fifth and tenth work interval. RPE was measured using the CR10 Borg scale. One-way repeated measures ANOVAs were used to determine HR and RPE responses across the HIIT session. Pearson correlations were utilized to assess relationships between HR and RPE. **RESULTS:** HR and RPE both significantly increased from the first (HR 157 ± 16 bpm; RPE 5.0 ± 1.8) to the fifth interval (HR 174 ± 14 bpm; RPE 6.8 ± 1.7 ; $p < 0.05$ for both). However, there were no significant differences in HR or RPE between the fifth and tenth interval (180 ± 12 bpm; RPE 7.7 ± 1.9 $p > 0.05$ for both). There were no significant relationships between HR and RPE for any of the time points ($r = -0.01$ to -0.34 , $p = 0.19$ to 0.89) or the average of the session ($r = 0.37$, $p = 0.16$). **CONCLUSIONS:** HR and RPE both increased initially during the HIIT session with no further increase after mid-point. There were no significant relationships between HR and RPE. These findings suggest that RPE, using the CR10 Borg scale, may not replicate HR for determining intensity during HIIT. Future research may be beneficial to determine a practical method for prescribing exercise intensity during HIIT. Further, it would be beneficial to examine the use of RPE and HR as methods of prescribing intensity in long-term, real-world intervention studies.

Perception Of Moderate Intensity Physical Activity By Onset Of Obesity: A Randomized Crossover Trial
 Kristie Rupp¹, Ciarán P. Friel². ¹Southern Connecticut State University, New Haven, CT. ²Columbia Medical Center, New York, NY.
 Email: ruppki@southernct.edu
 (No relevant relationships reported)

Moderate intensity physical activity is typically recommended for inactive adults with overweight or obesity. However, it is unknown whether there is a difference in the perception of moderate intensity by onset of obesity (childhood versus adulthood). **PURPOSE:** To determine if there was a difference in selection of moderate intensity between inactive adults with juvenile-onset (JO) and adult-onset (AO) overweight or obesity. **METHODS:** Participants ($N=38$; JO=18 and AO=20) completed an initial study visit where height, weight, fitness (time to 85% of age predicted HR_{max}), and weight history (modified Cincinnati Weight History Questionnaire) were assessed. After stratification by age of obesity onset, participants were randomly assigned the order to complete 20-minute moderate intensity exercise sessions on the treadmill and cycle ergometer (separate visits). A standardized script was used to instruct participants to exercise at a moderate intensity. Participants were given an opportunity to change the speed of the treadmill or cycle ergometer power output every 5 minutes of the session. VO_2 , METs, and HR were measured continually during exercise sessions. Multiple linear regression was used to determine whether exercise intensity (average MET value and % age-predicted HR_{max}) differed significantly between onset groups while controlling for age and gender. **RESULTS:** On the treadmill, JO and AO participants selected an average intensity of (mean \pm sd) 3.5 ± 0.9 vs. 3.7 ± 0.9 METs which equated to 64.0 ± 7.7 and 64.9 ± 7.5 % of their age-predicted HR_{max} , respectively. On the cycle ergometer, JO and AO participants selected an average intensity of 3.3 ± 0.9 vs. 3.3 ± 1.0 METs. This represented 65.2 ± 8.8 and 60.7 ± 7.2 % of their age-predicted HR_{max} , respectively. After adjusting for age and gender, AO participants expended on average 0.13 more METs on the ergometer (0.03 METs on the treadmill) than JO participants ($p=0.50$, 0.90 , respectively). For HRmax, findings were similar ($\beta=0.34$, -0.01 ; $p=0.08$, 0.95) for the ergometer and treadmill, respectively. **CONCLUSION:** Perception of moderate intensity did not differ by onset of obesity. However, inactive individuals with obesity selected an intensity at the low end of moderate intensity for both treadmill and cycle exercise resulting in lower overall energy expenditure.

Conditioned Pain Modulation And Blood Pressure Responses To Cold Pressor Test Among Resistance Exercisers
 Masataka Umeda¹, Akiko Okifuji². ¹University of Texas at San Antonio, San Antonio, TX. ²University of Utah, Salt Lake City, UT.
 Email: masataka.umed@utsa.edu
 (No relevant relationships reported)

Conditioned pain modulation (CPM) examines central pain inhibitory processing by assessing changes of sensitivity to the first pain stimulus after exposure to the second pain stimulus compared to baseline, and serves as risk factor of chronic pain. Aerobically-trained individuals typically show greater CPM compared to controls, but little is known regarding CPM among resistance exercisers (REs) who habitually engage in resistance exercise/strength training. REs often show elevated resting blood pressure (BP), which is associated with greater BP responses to cold pressor test (CPT) of immersing a hand into a cold water bath. Given past research showing the positive association between CPM and BP responses to CPT as the second pain stimulus, REs may exhibit greater CPM, along with augmented BP responses to CPT. **Purpose:** To compare CPM and BP responses to CPT between REs and controls. **METHODS:** REs were primarily recruited from weight lifting and power lifting teams ($n = 15$). Controls were healthy, normally active individuals (NAs) ($n = 15$). The participants completed the CPM test to evaluate changes in pain ratings (0-100) to electrical stimuli delivered to the ankle after CPT for a maximum of 2 minutes compared to baseline. The magnitude of CPM was calculated as change scores: post-CPT pain ratings - baseline pain ratings, with smaller pain ratings indicating greater pain inhibition. BP was assessed at baseline and every minute during CPT. CPM and BP data were analyzed using a mixed model ANOVA. The relationship between CPM and BP was tested using a correlational analysis. **Results:** Each group consisted of young, 9 men and 6 women (REs: 23 ± 5 yrs vs. NAs: 22 ± 2 yrs, $p > 0.05$). REs reported spending 9.1 ± 4.5 hours/week for resistance exercise. REs and NAs exhibited comparable CPM (Change scores. REs: -12 ± 12 vs. NAs: -14 ± 12 , $p > 0.05$), but REs showed greater systolic BP responses to CPT compared to NAs (Mean SBP. REs: 129 ± 11 mmHg vs. NAs: 119 ± 14 mmHg, $p < 0.05$). No significant association was found between systolic BP and CPM in REs (Resting: $r = 0.2$, $p > 0.05$ & Reactivity: $r = -0.2$, $p > 0.05$), but resting

systolic BP was positively associated with CPM in NAs (Resting: $r = 0.5$, $p < 0.05$ & Reactivity: $r = -0.1$, $p > 0.05$). **Conclusion:** The role of BP in CPM is likely complex, and the potential role of exercise in central pain processing needs to be studied.

Psychological Flexibility And Catastrophizing Predict Pain Interference In Veterans With Chronic Pain: Physical Therapy Considerations

Jennifer L. Gansen¹, Jennifer L. Delventura², MaryElizabeth Hammons², Aaron J. Stegner¹, Dane B. Cook, FACSM¹.
¹University of Wisconsin-Madison, Madison, WI. ²Atlanta VA Healthcare System, Atlanta, GA. (Sponsor: Dane B. Cook, FACSM)

(No relevant relationships reported)

The opioid crisis has made imperative the need for effective biopsychosocial interventions for chronic pain. The Empower Veterans Program (EVP) at the Atlanta VA is an interdisciplinary 10-week outpatient program involving group psychoeducation, psychotherapy, and physical therapy for Veterans with chronic pain. The aim is to improve patients' self-management of pain through increasing coping skills and functioning. Increasing psychological flexibility, the ability to persist or change behavior in pursuit of goals and values, and decreasing pain catastrophizing are two processes that may contribute to the impact of pain, and therefore may influence the efficacy of physical therapy.

PURPOSE: To determine whether psychological flexibility and pain catastrophizing predict pain interference in Veterans with chronic pain.

METHODS: Baseline measures were assessed in a sample (N=373) of Veterans enrolling in EVP. Stepwise linear regression was used to predict self-reported pain interference (Multidimensional Pain Inventory- Interference/MPI). Model predictors included general and pain-specific measures of psychological flexibility (General = Acceptance and Action Questionnaire/AAQ-II; Specific = Chronic Pain Acceptance Questionnaire/CPAQ), pain catastrophizing (Pain Catastrophizing Scale/PCS), and average pain intensity (Numeric Rating Scale/NRS). Demographic (age, gender and race) and physical performance (Timed Up and Go) were included in the model as covariates.

RESULTS: Sample characteristics were age (55.5 ± 0.4), gender (69.2% male), and race (15.9% white/ 79.1% black). The overall adjusted R² of the model was 0.48 ($p = 0.008$). Psychological flexibility (CPAQ $\beta = -.26$; AAQ $\beta = .23$), pain catastrophizing (PCS $\beta = .15$), and pain intensity (NRS $\beta = .24$) were significant predictors of pain interference.

CONCLUSIONS: Psychological flexibility and pain catastrophizing are two important psychological processes that contribute to pain interference. Rehabilitation strategies should consider the impact and response to treatment related to these constructs, especially aligning exercise and physical activity with values and behavior change principles.

The Influence Of Sex And Cuff Width On Discomfort To Blood Flow Restriction In The Lower Body

Robert W. Spitz¹, Raksha N. Chatakondi¹, Zachary W. Bell¹, Vickie Wong¹, Ricardo B. Viana¹, Scott J. Dankel², Takashi Abe¹, Yujiro Yamada¹, Jeremy P. Loenneke, FACSM¹. ¹The University of Mississippi, University, MS. ²Rowan University, Glassboro, NJ. (Sponsor: Jeremy P. Loenneke, FACSM)

Email: rwsplitz@go.olemiss.edu
 (No relevant relationships reported)

Wide cuffs cause arterial occlusion at lower pressures but may produce greater discomfort immediately following blood flow restricted exercise compared to more narrow cuffs in the upper body. Whether this is true in the lower body or if this differs by sex is currently unknown. **PURPOSE:** To determine the impact of cuff width, sex, and pressure on perceived discomfort in the lower body. **METHODS:** Experiment 1 (n=99) compared discomfort at rest between a 5 and 12 cm cuff. Experiment 2 (n=96) compared discomfort between a 5 and 12 cm cuff after four sets of knee extension exercise. For Experiments 1 and 2, the cuffs were inflated to 40% of the arterial occlusion pressure for each cuff. Experiment 3 (n=95) used the same exercise protocol as Experiment 2 to compare the discomfort between a 12 cm cuff inflated to pressure meant for a narrow cuff and a 12 cm cuff inflated to the appropriate pressure. Discomfort was rated following the 4th set (0: no discomfort, 100: maximal discomfort). Following the exercise bout in Experiments 2 and 3, participants were asked to choose which condition they would prefer to use regularly. A Bayesian repeated measures analysis with a between subject factor of sex was used to assess differences in discomfort. A contingency table was used to determine if cuff preference differed by sex. Bayes Factors (BF₁₀) were used to quantify evidence. **RESULTS:** In Experiment 1, the narrow cuff had higher discomfort than the wide cuff [16 vs 12 AU, BF₁₀=31]. In Experiment 2, men reported greater discomfort [58 vs 48 AU, BF₁₀=4.9], however, there were no differences in discomfort (52 vs. 53 AU) between

cuffs [median difference (95% credible interval) of -0.5 (-3, 1.8) AU, BF₁₀=0.17]. Narrow cuffs were preferred by most participants. Experiment 3 found cuffs inflated to pressure intended for narrow cuffs had greater ratings of discomfort [73 vs 52 AU, BF₁₀=1.2e+19] and participants preferred to use it less. Of note, the pressure for the 5 cm cuff had to be estimated for the majority of participants. **CONCLUSIONS:** The inability to directly assess arterial occlusion on the majority of the sample limits the conclusions that can be made. There was no strong evidence that discomfort differed between cuff widths though there was some indication that participants preferred the narrow cuff and the cuff inflated to the appropriate relative pressure.

2351 Board #270 May 28 2:00 PM - 3:30 PM
The Perceptual Responses Of Multiple Sclerosis Patients To Traditional Versus Blood Flow Restriction Resistance Exercise

Eduardo D. S. Freitas, Ryan M. Miller, Aaron D. Heishman, Japneet Kaur, Keldon M. Peak, Cameron Combs, Debra A. Bembem, FACSM, Rebecca Larson, Hugo M. Pereira, Michael G. Bembem, FACSM. University of Oklahoma, Norman, OK. (Sponsor: Michael G. Bembem, FACSM)

(No relevant relationships reported)

PURPOSE: To investigate the perceptual responses (ratings of perceived exertion [RPE] and discomfort [RD]) of multiple sclerosis patients (MS) to low-load resistance exercise (RE) with blood flow restriction (BFR) and to traditional high-load RE without BFR. **METHODS:** Thirteen individuals (males = 3, females = 10) with a confirmed diagnosis of relapsing-remitting MS were randomly assigned to the following RE conditions: 1) low-load RE with BFR (LL-BFR) and 2) high-load RE without BFR (HI). Participants performed 4 sets (30-15-15-15 reps) of bilateral leg press (LP) and knee extension (KE), at 20% of their one-maximum repetition (1-RM), and with 50% of BFR for the LL-BFR exercise trial. For the HI exercise condition, participants completed 4 sets (10-10-10-10 reps) of the same exercises at 70% of 1RM. There was a 3-minute rest period between sets and 5 minutes between exercises. RPE was assessed after each set using the OMNI-RES scale, with scores ranging from 0 to 10. The RD were assessed immediately before and after each set using a visual numeric pain scale, with scores ranging from 0 to 10. Data were analyzed using the Friedman's and the Wilcoxon non-parametric tests with Bonferroni correction, and with p set at 0.05. Data are winsorized means \pm SD. **RESULTS:** Greater RPE values were observed for the HI exercise condition compared to LL-BFR following the first set of LP (6.83 ± 1.17 vs 4.84 ± 2.05 , $p < 0.05$), but not after sets 2 (6.83 ± 1.48 vs 4.2 ± 2.14), 3 (7.62 ± 1.63 vs 4.82 ± 2.09), and 4 (7.94 ± 1.44 vs 4.98 ± 1.87). During KE, HI elicited significantly ($p < 0.05$) higher RPE after sets 2 (8.07 ± 1.06 vs 6.47 ± 1.52), 3 (8.86 ± 1.02 vs 6.84 ± 1.26), and 4 (9.02 ± 1.17 vs 6.84 ± 1.26 , but not set 1 (8.24 ± 0.66 vs 6.54 ± 1.74). For the RD, LL-BFR induced significantly ($p < 0.05$) greater RD than HI only after the first set of both LP (2.26 ± 1.46 vs 0.80 ± 0.54) and KE (4.69 ± 1.80 vs 2.52 ± 1.65). For the RD measured immediately before each set, LL-BFR was significantly greater ($p < 0.05$) than HI only before sets 3 (3.13 ± 1.41 vs 0.52 ± 0.68) and 4 (3.14 ± 1.92 vs 1.10 ± 1.09) of LP, and before sets 2 (3.75 ± 1.93 vs 0.94 ± 1.10) and 3 (3.15 ± 1.41 vs 1.15 ± 0.96) of KE. **CONCLUSION:** LL-BFR results in similar RPE and RD compared to HI. However, the RD perceived immediately before a subsequent set remained partially elevated following some of the sets of LL-BFR.

Re-occurrence Of Oscillatory Ventilation During Cardiopulmonary Exercise Testing Post Left Ventricular Assist Device Implantation

Miranda Contursi, MS, John Boehmer, MD. Hershey Medical Center, Hershey, PA.

(No relevant relationships reported)

Oscillatory ventilation, characterized by cyclic fluctuations in minute ventilations, is recognized as a significant prognostic indicator of adverse outcomes in heart failure patients. Assessing for exercise induced oscillatory ventilation (EOV) during cardiopulmonary exercise tests (CPET) is a valuable non-invasive parameter in evaluating HF. Various reversibility studies using pharmacological, valvular surgery, cardiac transplantation, exercise training, and nocturnal adaptive servo-ventilation have been associated with an attenuation of EOV, but no studies have assessed if the incidence of EOV is reduced post LVAD implantation during routine CPET.

PURPOSE: To quantify the reoccurrence of EOv during CPET in HF patients that previously demonstrated EOv during a CPET prior to their LVAD implantation surgery.

METHODS: A retrospective analysis of HF patients that received LVAD implantation surgery from 1988-2018 was conducted. CPET data was collected and evaluated for EOv from patients that had testing done within one year both pre and post LVAD. EOv was defined as oscillatory ventilations that persist for at least 60% of the exercise test and amplitude of 15% or more of the average resting value.

RESULTS: Among 325 participants with LVAD's, 32 underwent CPET testing within one year both pre and post-surgery. Basic demographics are as follows: 81% male, age = 57 ± 8.8, and BMI = 32 ± 7. Forty four percent (n=14) of the participants demonstrated EOv during their pre LVAD CPET and 12% (n=4) demonstrated EOv on their post LVAD. This represents a 71% decrease in the occurrence of EOv which is significant at p<.05. No participant newly developed EOv post LVAD.

CONCLUSION: Among HF people with EOv during a CPET, LVAD implantation is associated with an attenuation of EOv. Future study is warranted to determine if EOv post LVAD correlates with early hospital re-admission or cardiovascular mortality.

Figure. Ventilation from a representative patient before and after LVAD implantation surgery displaying reduction of amplitude and cycle length of EOv

METHODS: A total of 117 female participants (age: 38.7 ± 7.6 years) underwent muscle mass (dual-energy x-ray absorptiometry), muscle strength (*knee extensors* isokinetic *peak torque at 60 °/s*), and physical function (sit-to-stand, timed up-and-go, and six-minute walk tests) evaluation. *Spearman's rank correlation coefficient* was used to identify associations. Mann-Whitney U test was used to compare the physical function of participants in the lowest and highest quartiles of muscle mass and strength.

RESULTS: The table below presents the association between muscle mass, muscle strength and physical function. Of the studied muscle-related phenotypes, only muscle strength was significantly related to physical function. Compared to the highest quartile of muscle strength, participants in the lowest quartile exhibited significantly worse performance in the timed-up and go test (6.3 ± 0.9 s vs. 5.8 ± 0.9 s; p= 0.048), but did not reach statistical significance the sit-to-stand (14.6 ± 2.9 vs. 16.3 ± 4.0; p= 0.124) and six-minute walk (569.6 ± 54.9 m vs. 599.8 ± 82.1 m; p= 0.178) tests.

CONCLUSION: Muscle strength, but not muscle mass, is associated with physical function in long-term gastric by-pass women; which support a growing body of evidence demonstrating that strength has a better prognostic value compared to muscle mass to predict worsening disability.

Keywords: Gastric bypass, Muscle strength, physical functional performance.

The association between muscle mass, muscle strength and physical function in long-term gastric by-pass women.		
	Muscle mass	Muscle strength
Sit-to-stand test	-0.112	0.245*
Timed up-and-go test	0.120	-0.216*
Six-minute walk test	0.096	0.198*

* Denotes significant correlation (p<0.005).

Clinical Application Of Duke Activity Status Index To Select An Appropriate Cardiovascular Stress Test Protocol

Mary Ann Reynolds, Rachel Myers, Josh West, Katey Sweat, Virginia McGhee, Hem Bhardwaj, W. Greg Hundley, Ross Arena, FACSM, Justin Canada. *Virginia Commonwealth University, Richmond, VA.* (Sponsor: Ross Arena, FACSM)
(No relevant relationships reported)

Patients referred for cardiovascular stress testing with limited functional capacity due to age, deconditioning, or clinical comorbidities may be unable to achieve an adequate exercise stress level to render a diagnostic cardiovascular stress test. The Bruce treadmill protocol is the current clinical standard, but may be inappropriate for some patients due to large changes in speed/grade between stages. The Duke Activity Status Index (DASI), a validated 12-item questionnaire that utilizes self-reported physical work capacity to estimate metabolic equivalents (METs), may help clinicians select the most appropriate stress test protocol. **PURPOSE:** To determine if DASI estimated MET levels can predict the achievement of an adequate diagnostic exercise stress test using the Bruce treadmill protocol. **METHODS:** DASI questionnaires were administered to patients prior to stress testing. DASI estimated METs were calculated from the total score. Measured METs were determined from peak treadmill speed and grade. Criteria for determining a suboptimal exercise stress was defined as inability to complete stage 1 of a Bruce protocol. **RESULTS:** A total of 400 patients completed the DASI questionnaire. Mean DASI estimated METs and measured METs were 8.1 ± 1.7 and 8.4 ± 2.8, respectively. Logistic regression analysis showed DASI estimated and measured METs predicted a suboptimal test result (P<0.001). Receiver operator characteristic curve (Figure 1) demonstrated a DASI estimated MET level ≤ 7.4 was the optimal threshold to predict a suboptimal test result, AUC=0.883, SE=0.037 (0.811-0.956), sensitivity= 94%, specificity= 73%, P<0.0001. **CONCLUSIONS:** Findings suggest the Duke Activity Status Index may be an effective way to stratify stress type in the clinical setting. Further study is needed to assess if more conservative exercise protocols with smaller incremental changes in workload would increase the likelihood of achieving a diagnostic cardiovascular stress result.

Muscle strength, but not mass, is associated with physical function in long-term gastric by-pass women

Muscle-related phenotypes have been linked to physical function in the general population; however, this relationship has yet to be examined in long-term gastric by-pass women.

PURPOSE: To examine the association between muscle mass, muscle strength and physical function in women who have been doing gastric by-pass for over 2 years.

Does Low Volume, High-intensity Interval Training Impact Right Ventricular Size And Function?

Meriam Åström Aneq¹, Kristoffer Hedman¹, Eva Nylander¹, Karin Bouma², Mirko Mandic³, Eric Rullman³. ¹Institution for Medicine and Health Sciences, Linköping, Sweden. ²Karolinska Institutet, Stockholm, Sweden. ³Karolinska institutet, Stockholm, Sweden.

Email: meriam.astrom.aneq@regionostergotland.se
(No relevant relationships reported)

PURPOSE

The minimum volume of exercise training required for the right ventricular (RV) adaptation's changes to occur is unknown. We aimed to determine possible effects on RV size and function with extremely low volume, high-intensity exercise training (HIT) in previously untrained subjects.

METHODS

Healthy, young subjects not performing regular training were recruited for six weeks of supervised HIT, three times per week. Each of the 18 sessions consisted of three 30 seconds all-out sprints on a bicycle ergometer (breaking force 7.5% of the subject's body weight), separated by two minutes of low intensity cycling. A maximal cardiopulmonary exercise test (CPX) and an echocardiogram (echo) at rest were performed before and the week after the last session. Right atrial volume (RAV), RV inflow-tract diameter (RVId) and end diastolic area (RVEDA) were measured. RV systolic function was determined as fraction area change (FAC), tricuspid annular plane systolic excursion (TAPSE) and global longitudinal strain based on 2D speckle tracking in 6 segments of free wall and septum (RVGs).

RESULTS

Maximal oxygen uptake ($\dot{V}O_2$ max) was determined in 27 subjects and increased from 3.0 ± 0.8 L/min to 3.4 ± 0.8 L/min post training, mean +14%, $p < 0.001$. Pre- and post HIT echo data were available in 28 subjects (27±5 yrs, 16 male, BMI 24 ± 2 kg/m² (18-28). RVEDA was larger post training (19.6 ± 4.1 vs 18.3 ± 3.6 cm², $p = 0.003$) while RVId showed no difference (3.7 ± 0.4 vs 3.7 ± 0.5 cm, $p = 0.9$). FAC, TAPSE and RVGs remained unchanged after the training period (51.3 ± 7 vs $52.9 \pm 6\%$, $p = 0.2$; 2.4 ± 0.3 vs 2.8 ± 1.8 cm, $p = 0.3$; -23.1 ± 3.6 vs $-22.9 \pm 3.6\%$, $p = 0.6$). RAV showed a tendency to larger values post training but not statistically significant (46.0 ± 15.7 vs 49.6 ± 17.3 mL, $p = 0.07$). There was a significant correlation between $\dot{V}O_2$ max, RVEDA and RAV at baseline and post training ($r^2 = 0.32$, $p = 0.003$ resp. $r^2 = 0.21$; $p = 0.01$ and $r^2 = 0.20$, $p = 0.04$ resp. $r^2 = 0.45$, $p = 0.0001$).

CONCLUSION

Larger RV chamber size was present after less than 5 min high-intensity exercise training per week for six weeks. This was not proportional to changes in $\dot{V}O_2$ max. The systolic RV function remained unchanged.

Peak Responses To Graded Exercise Protocols In Young Children

Tori L. Vogelaar, Lilly A. Bradley, Kathryn R. Lanphere, Mark Vranicar, Jody L. Clasey, FACSM. University of Kentucky, Lexington, KY. (Sponsor: Jody L. Clasey, FACSM)
(No relevant relationships reported)

The Bruce protocol (Bruce) is a progressive treadmill test with an aggressive initial grade that was developed for use in adults, and is often used to assess cardiac patients. Due to the steep grade, young children may terminate the Bruce prematurely. The University of Kentucky Pediatric Exercise Physiology Lab has developed a protocol (PEP Lab) with lower grades which we hypothesized would be better tolerated and potentially elicit greater peak $\dot{V}O_2$ and cardiovascular responses. **PURPOSE:** To compare peak oxygen uptake ($\dot{pV}O_2$; ml·kg⁻¹·min⁻¹), heart rate (pHR; bpm), systolic blood pressure (pSBP; mmHg), and respiratory exchange ratio (pRER) responses to the Bruce versus the PEP Lab in 43 (22 boys) young (7-11 yr old) children of varying adiposities. We also evaluated each subject's perception of difficulty between the two protocols.

METHODS: Subjects completed the Bruce and the PEP Lab protocols in a random order 1 week apart. $\dot{pV}O_2$ and pHR were determined with an integrated metabolic system, and pSBP was determined by manual auscultation. Verbal encouragement was provided during both testing sessions and test completion based on volitional fatigue. Results are expressed as mean ± SE and significance $p < 0.05$.

RESULTS: The Bruce versus PEP Lab $\dot{pV}O_2$ (43.6 ± 1.5 vs 43.9 ± 1.5) and pHR (186.6 ± 2.0 vs 188.2 ± 2.2) did not significantly differ. However, pSBP during the Bruce was significantly lower (136.4 ± 1.4 vs 141.3 ± 1.1) and the Bruce pRER was significantly higher (1.065 ± 0.018 vs 1.013 ± 0.014) than the PEP Lab. Bruce and PEP Lab protocol $\dot{pV}O_2$, pHR, pSBP, pRER were significantly correlated ($r = 0.61, 0.47, 0.53$ and 0.42 , respectively). The majority (88%) of the children perceived the Bruce to be more difficult.

CONCLUSIONS: A less steep protocol can elicit similar cardiopulmonary results as the Bruce. Protocols that are perceived as less difficult may help guarantee that children do not terminate their exercise tests prematurely to reaching their true $\dot{pV}O_2$. Supported by the University of Kentucky Pediatric Exercise Physiology Lab Endowment; NIH National Center for Advancing Translational Sciences through grant number UL1TR001998. Ventilatory Constraint Analysis During Maximal Exercise Testing In Elite Youth Athletes

Steven R. Boas, FACSM¹, Pranay S. Prabhakar¹, Sabina Bukowska¹, Lorena Rosiles¹, Tony G. Babb, FACSM². ¹The Sports Physiology Center of Chicago, Glenview, IL. ²The Institute for Exercise and Environmental Medicine, Texas Presbyterian Hospital Dallas and The University of Texas Southwestern Medical Center, Dallas, TX, Dallas, TX.
Email: sboas@wecare4lungs.com
(No relevant relationships reported)

PURPOSE: Assessment of ventilatory constraint has become essential in the assessment of exercise performance. However, minimal data exists regarding a systematic evaluation of these constraints in an elite athletic population. The study was performed to provide new normative data and preliminary analysis of how these variables correlate.

METHODS: Twenty four individuals were analyzed as part of a human performance evaluation. 16 individuals competed in Div 1 soccer (16F, age 18-22 yrs) and 8 in AAA hockey (8M, age 13-14 yrs). A graded maximal exercise test was performed (Bike: Lode Excalibur) with breath by breath gas analysis (Med Graphics). Expiratory flow limitation (EFL%), VE/MVV, ventilatory reserve capacity (VRC%), shift in EELV (IC/VC%), shift in EILV (VT/IC%), and inspiratory reserve (IR) were recorded. Spearman coefficients were determined between ventilatory constraint and exercise variables. Unpaired Student t tests were performed for comparison within constraint variables. Values are expressed as mean±SD with significance set at $p < 0.05$.

RESULTS: All constraint variables were obtained except IR (incomplete data). EFL% (37.8 ± 26.5), VRC% (90.2 ± 1.7), IC/VC% (65.1 ± 8.9), VE/MVV% (100.4 ± 8.5) and VT/IC% (83.5 ± 7.7) did not vary by sport. EFL% correlated to VRC% ($r = 0.57$, $p < 0.05$) and weakly correlated to IC/VC% ($r = 0.35$, $p = 0.09$) but not VE/MVV% or VT/IC%. No relationship existed between the remaining variables. $\dot{V}O_2$ (ml/kg lean body mass) was higher for VE/MVV >100% than <100% (64.2 ± 6.1 vs 59.9 ± 3.4 , $p < 0.05$). Peak work capacity (PWC)/LBM, % of predicted, was similarly affected (142.5 ± 10.5 vs 153.6 ± 10.2 , $p < 0.05$). For IC/VC%, higher PWC (297.7 ± 47.3 vs 265.8 ± 22.3 Watts, $p < 0.05$)

and VO_2 (3.32 ± 0.51 vs 2.98 ± 0.29 liters, $p < 0.05$) were seen in the low IC/VC group (<65%) compared to the high group (>65%). EFL% and VT/IC% did not correlate with PWC or VO_2 .

CONCLUSIONS: Ventilatory constraint analysis yielded normative data. EFL was associated with ventilatory reserve. However, unlike previous data in cystic fibrosis, VE/MVV was not correlated to ventilatory constraint. While a shift in EELV (IC/VC%) may be considered abnormal in underlying respiratory diseases, the ratio in this study was associated with increased exercise performance reflecting different underlying compensatory breathing mechanics.

The Index Of Physical Performance In Muscle Damage Biomarker In Youth Athletes

Tsai-Hsuan Ho, Linda Li-chuan Lin, Wei-Chi Tseng, Chun-Kai Tsai. *National Cheng Kung University, Tainan, Taiwan.*
 Email: ohetya@gmail.com
 (No relevant relationships reported)

PURPOSE: To investigate the index of the physical performance among different levels of serum creatine kinase in youth athletes.

METHODS: 53 youth male athletes ages of 12 to 18 years were divided into three groups, low-level group (LL, $n=17$), middle-level group (ML, $n=20$), and high-level group (HL, $n=16$) by CK level of serum (reasonable CK range: 82-1,083 U/L for male athletes). Fasting blood samples of CK and myoglobin were collected in the morning. The physical performance test included gripping, low back muscle strength, curl up, standing broad jump, lower limb flexibility, 30m sprint, vertical jump, whole-body reaction time, agility, and yo-yo test for aerobic endurance. One-way ANOVA and Pearson's correlation were used to determine the difference between physical performance and biomarkers.

RESULTS: In biomarkers, the value of CK had positive correlation between low back muscle strength ($r=0.278$, $p < 0.05$) and reaction time ($r=0.412$, $p < 0.01$). There was a negative correlation between CK and aerobic endurance ($r=-0.288$, $p < 0.05$). The myoglobin of LL (19.76 ng/ml) was significantly lower than ML and HL (25.18 ng/ml; 28.96 ng/ml) ($p < 0.05$). The aerobic endurance of LL was significantly higher (26.6%) than HL ($p < 0.05$). In the reaction time, LL and ML (267.12ms; 284.95ms) were significantly faster than HL (367.27ms) ($p < 0.05$). There were no significant differences in other physical performance.

CONCLUSIONS: This study suggested that the performance of whole-body reaction time and yo-yo test perhaps to be reminded for muscle damage or fatigue in the reasonable CK range. In addition, future research can regularly implement both physical indexes to track muscle fatigue.

Chronotropic Intolerance In Patients With Chronic Lyme Disease Identified By Serial Cardiopulmonary Exercise Testing

Saejel G. Mohan¹, Courtney D. Jensen², Staci Stevens³, Jared Stevens³, Todd Davenport², J. Mark VanNess². ¹University of California at Berkeley, Berkeley, CA. ²University of the Pacific, Stockton, CA. ³Workwell Foundation, Ripon, CA.
 (No relevant relationships reported)

In the U.S., annual incidence of Lyme disease is approximately 300,000. In an estimated 5-30% of cases, post-treatment Lyme disease syndrome (PTLDS) develops; symptoms include post-exertional malaise characteristic of myalgic encephalomyelitis. The contribution of autonomic regulation has not been elucidated. **PURPOSE:** To evaluate cardiovascular responses to serial cardiopulmonary testing in patients with PTLDS. **METHODS:** 14 patients with PTLDS and 8 sedentary controls underwent 2 maximal exercise tests separated by 24 hours. Heart rate (HR) was measured continuously via electrocardiogram. Expired air was collected for determination of anaerobic threshold (AT) using V-slope methodology and maximal exertion was defined as a respiratory exchange ratio > 1.09 . Independent-samples t-tests compared baseline characteristics of PTLDS patients and controls. Linear regression determined the effect of PTLDS diagnosis on HR at AT and peak holding workload constant. **RESULTS:** Patients were 44.0 ± 10.1 years old, weighed 69.8 ± 16.2 kg, and achieved a peak VO_2 of 23.8 ± 6.2 mL/kg/min during test 1. HR was 116.2 ± 21.8 bpm at AT and 162.6 ± 25.1 at peak. PTLDS and controls did not differ in peak VO_2 during test 1 ($p=0.161$), test 2 ($p=0.134$), or the difference between test 1 and test 2 ($p=0.498$). HR at AT was comparable in test 1 ($p=0.127$) but different in test 2 ($p < 0.001$). HR at peak was different in test 1 ($p=0.001$) and test 2 ($p < 0.001$). During test 1, holding workload constant, PTLDS patients had lower peak HR by 19.5 bpm ($p=0.033$; 95% CI: -37.3 to -1.8). During test 2, holding workload constant, PTLDS predicted a lower HR by 26.8 bpm at AT ($p=0.004$; 95% CI: -43.9 to -9.8) and 24.3 bpm at peak ($p=0.007$; 95% CI: -40.9 to -7.7). **CONCLUSIONS:** Patients with PTLDS demonstrated abnormal cardiovascular responses to exercise. Despite accomplishing the same VO_2 , and holding workload constant, the HR response was diminished in the post-exertional state, potentially indicating dysautonomia in PTLDS.

Normalizing Cardiorespiratory Fitness To Fat-free Mass Improves Mortality Risk Prediction In Overweight Adults From The Ball St Cohort

Mary T. Imboden¹, Leonard A. Kaminsky, FACS², James E. Peterman², Haylee L. Hutzler², Mitchell H. Whaley, FACS², Bradley S. Fleenor², Matthew P. Harber, FACS². ¹George Fox University, Newberg, OR. ²Ball State University, Muncie, IN.
 (Sponsor: Matthew P Harber, FACS²)
 Email: mimboden@georgefox.edu
 (No relevant relationships reported)

PURPOSE: Cardiorespiratory fitness (CRF) is a significant predictor of mortality outcomes in various populations, including overweight and obese adults. However, CRF is commonly expressed normalized to total body weight ($\text{VO}_{2\text{peakTBW}}$) which may weaken the relationship in obese adults as fat-free mass (FFM) is directly related to CRF, and increased body fat is associated with lower CRF in adults. Therefore, this study aimed to assess the relationship between CRF normalized for FFM ($\text{VO}_{2\text{peakFFM}}$) and all-cause mortality, as well as compare the predictive ability of $\text{VO}_{2\text{peakFFM}}$ and $\text{VO}_{2\text{peakTBW}}$ in a cohort of self-referred overweight and obese adults.

METHODS: Participants included 1,021 overweight and obese adults (520 men, 501 women; BMI: 30.8 ± 5.3) who completed a cardiopulmonary exercise test (CPX) and body composition assessment between 1970-2016 to determine CRF. Participants were included if their BMI > 25 kg·m⁻² and/or waist circumference was > 88 cm in women and > 102 cm in men. FFM was estimated using the skinfold method to estimate FFM. Participants were followed for 17.8 \pm 10.8 years after their CPX and body composition assessments for mortality outcomes. Cox-proportional hazard models were performed to determine the relationship of $\text{VO}_{2\text{peakFFM}}$ with mortality outcomes. A Wald Chi-square test of equality was performed to compare the predictive ability of CRF expressed as $\text{VO}_{2\text{peakTBW}}$ and $\text{VO}_{2\text{peakFFM}}$.

RESULTS: Overall, $\text{VO}_{2\text{peakFFM}}$ was inversely related to all-cause mortality, with an 11.8% lower risk per 1 mL·kgFFM⁻¹·min⁻¹ improvement, respectively ($p < 0.01$). $\text{VO}_{2\text{peakFFM}}$ was shown to be a significantly stronger predictor of all-cause mortality than $\text{VO}_{2\text{peakTBW}}$ (parameter estimates: -0.44 vs. -0.18, $p < 0.05$ respectively).

CONCLUSIONS: Body composition is an important factor when considering the relationship between CRF and mortality risk. Clinicians should consider normalizing CRF to FFM when feasible, especially in individuals with excess body fat as it will strengthen the predictive power of the measure.

Hemodynamic Performance In Patients With A Bicuspid Aortic Valve During Treadmill Ramp Exercise Testing

Mallorie C. Rice, Wayne A. Mays, Andrea L. Grzeszczak, Sandra K. Knecht, Justine D. Shertzer, Samuel G. Wittekind, Clifford Chin, Adam W. Powell, Michael Khoury. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*
 Email: Mallorie.Rice@cchmc.org
 (No relevant relationships reported)

PURPOSE: To evaluate the effect of a bicuspid aortic valve on the hemodynamic response to a treadmill ramp protocol in pediatric patients. **METHODS:** We evaluated 18 patients with a bicuspid aortic valve (BAV) and 18 normal subjects (C), age and size matched, using a Ramp Treadmill protocol. Neither group was treated with a Beta Blocker. Resting aortic valve peak gradient (PG) and shortening fraction (SF) were evaluated by echocardiography for the BAV group. Systolic blood pressure (SBP), cardiac output and stroke volume (SV) were obtained at rest and maximal exercise. Maximal oxygen pulse (MO2P), percent predicted oxygen pulse (%PO2P) and respiratory exchange ratio (RER) were obtained at maximal exercise. **RESULTS:** There were no significant differences between the BAV and C groups in age (14.6 ± 2.1 vs 15.8 ± 3.1 (yr)), height (1.63 ± 0.1 vs 1.66 ± 0.12 (m)) or weight (55.7 ± 15.1 vs 57.6 ± 13.2 (kg)). The BAV group had a resting PG of 16.5 ± 8 mmHg and a SF of 39.5 ± 4.9 %. The SBP in the BAV group was significantly decreased at rest (113 ± 9 vs 120 ± 10 mmHg) $p < 0.05$ and exercise (160 ± 14 vs 174 ± 19 (mmHg) $p < 0.02$) compared to the C group. BAV group had a significantly decreased SV (56 ± 13 vs 64 ± 21 (ml/beat) $p < 0.04$) compared to C at rest. The decreased MO2P in the BAV group approached significance (6.6 ± 1.7 vs 7.6 ± 1.6 ml/beat $P=0.06$) compared to C. In BAV, %PO2P was significantly decrease (94 ± 24 vs 113 ± 18 (%)) $p < 0.01$. Max RER was not significantly different in BAV and C groups (1.19 ± 0.08 vs 1.19 ± 0.06). MO2P significantly correlated to cardiac output ($r=0.67$ $p < 0.05$). Significance was set at $p < 0.05$. **CONCLUSION:** BAV and C groups reached the same intensity of exercise as reflected by the RER. The BAV group had decreased systolic blood pressure and O2Pulse response to exercise. These data suggest that in the face of a mild aortic valve gradient and normal shortening fraction, these BAV patients had a diminished hemodynamic response to exercise.

Predictors Of Achieving An Adequate Heart Rate Response During Cardiovascular Exercise Stress Testing

Rachel Myers. *Virginia Commonwealth University Health System, Richmond, VA.* (Sponsor: Ross Arena, FACSM)
 Email: Ramyers90@gmail.com
 (No relevant relationships reported)

Cardiovascular exercise stress testing is a noninvasive, diagnostic tool to assess for myocardial ischemia. Achievement of $\geq 85\%$ of age-predicted maximal heart rate (APMHR) is commonly used as criteria to define an adequate stress test. **PURPOSE:** The purpose of this study was to determine if patient characteristics could predict ability to achieve an adequate heart rate response during exercise stress testing. **METHODS:** Baseline characteristics including age, race, gender, height, weight, body mass index (BMI), referring provider type, Duke Activity Status Index (DASI) score and stress type (pharmacologic versus exercise) were collected on all patients who completed cardiovascular stress testing. All exercise tests were performed using a standard Bruce treadmill protocol. Criteria for determining an adequate exercise stress test was $\geq 85\%$ of age-predicted maximal heart rate. **RESULTS:** Out of 608 cardiovascular stress tests, 354 performed exercise stress. Patient characteristics of those who underwent exercise stress was as follows: female= 175 (49%), Caucasian=173 (47%), African American=146 (45%), mean age was 57 ± 13 years, mean BMI= 31.4 ± 8.1 kg/m², mean DASI estimated METS= 8.1 ± 1.7 and mean METS achieved= 8.4 ± 2.8 . Fifty-eight (19%) patients did not achieve $\geq 85\%$ APMHR. Exercise time, DASI estimated METS and METS achieved were significant predictors of achieving $\geq 85\%$ APMHR (all P's <0.02). Age, race, gender, height, weight, BMI, provider type were not significant (all P's >0.11). **CONCLUSIONS:** In conclusion, exercise duration during graded exercise testing predicted achievement of adequate stress response during cardiovascular stress testing. Strategies to select an appropriate exercise test protocol allowing longer exercise duration may improve the ability to reach target heart rate during cardiovascular stress testing.

Prediction of Suboptimal Effort (<85%PMHR) by DASI est.METS

AUC = 0.659 (0.589-0.730) P<0.0001

Optimal Threshold for Suboptimal Effort = 8.0 DASI est.METS
 Sensitivity=65%, Specificity=65%

Effect Of Combined Exercise On Lung Function, Blood Vitamin D, Calcium And Bone Metabolism Hormones In Elderly Women

Min-Jae Ki¹, Do-Yeon Kim¹, Soo-Min Ha¹, Jung-Sook Kim¹, Eadric Bressel², Jong-Won Kim³. ¹*Pusan National University, Busan, Korea, Republic of*; ²*Utah State University, Logan, UT.*; ³*Busan National University of Education, Busan, Korea, Republic of.*
 (No relevant relationships reported)

PURPOSE: This study was to investigate the effects of a combined exercise training regimen on lung function, blood vitamin D, calcium and bone metabolism hormones (calcitonin, osteocalcin) in elderly women. **METHODS:** Thirty healthy elderly female volunteers, were randomly assigned to combined exercise group (n=13) trained for 12-week or to a "non-exercise" control group (n=17). The combined exercise program was conducted for 60 minutes per session three times a week at the following intensities: Aerobic exercise intensity was 40-50%HRR (RPE 12-13) for 1-4 weeks, 50-60% HRR (RPE 13-14) for 5-8 weeks, and 60-70%HRR (RPE 14-15) for 9-12 weeks. Resistance exercise intensity was set at 3-4 in OMNI-RES for 1-4 weeks, 5-6 in OMNI-RES for 5-8 weeks, 7-8 in OMNI-RES for 9-12 weeks.

RESULTS: FEV1 showed interaction effects group \times time, FVC and FEV1 were significantly increased in the exercise group. Vitamin D and calcium showed interaction effects between group \times time, vitamin D was significantly increased in the both group, and calcium was decreased in the control group. Calcitonin and osteocalcin of bone metabolism showed interaction effects group \times time, osteocalcin was significantly decreased in control group. **CONCLUSIONS:** Our findings indicate that combined exercise were effective in improving the lung function and bone metabolism hormones in elderly women due to decreased physical activities.

Pilot Study On Effect Of Ipsilateral Long Kinetic Chains On Shoulder Elevation Strength

Andre A. Abadin, Edsel Bittencourt, Peter T. Dorsher, George G.A. Pujalte, FACSM. *Mayo Clinic, Jacksonville, FL.* (Sponsor: George G.A. Pujalte, FACSM)
 (No relevant relationships reported)

There is growing evidence to suggest that kinetic chains extend far beyond the core muscles, following myofascial meridians that interestingly appear to overlap with classically-known acupuncture channels. Strengthening programs during the rehabilitation of musculoskeletal injuries utilize kinetic chain exercises; however, how lower extremity strength potentially directly affects upper extremity strength has not been quantified. **PURPOSE:** To examine quantitatively the effect on shoulder elevation strength (SES) in the sagittal plane on ipsilateral lower extremity tibialis anterior muscle activation. **METHODS:** Twenty young healthy adult volunteers (half women, half men), ages 20-60 years, having no shoulder pain were recruited. Participants had baseline SES evaluated with a hand-held dynamometer applied just proximal to the radial styloid with the arm held in 90-degree elevation in the sagittal plane. The participants underwent the following interventions: SES and ipsilateral anterior tibialis muscle activation (IATMA) while standing, SES and IATMA while seated with legs dangling, and SES with ipsilateral gastrocnemius activation while seated with legs dangling. **RESULTS:** In females, IATMA, in standing and seated position, reduced SES by a mean percentage of 12.57 and 14.88, respectively, from baseline. SES with gastrocnemius activation (reciprocal relaxation of anterior tibialis) reduced SES by a mean percentage of 3.93 from baseline. In males, IATMA, in standing and seated position, reduced SES by a mean percentage of 5.58 and 10.84, respectively, from baseline. SES with gastrocnemius activation (reciprocal relaxation of anterior tibialis) reduced SES by a mean percentage of 3.3 from baseline. **CONCLUSIONS:** IATMA directly reduces SES; it also produces a greater decrement in SES compared to ipsilateral gastrocnemius activation. This kinetic chain effect appears coincident with known myofascial meridians.

Cardiovascular Response During Exercise In Patients With Hypertension And Patients With Hypertension With Diabetes

Wang Panyue, Yan Yan, Wang Yan, Wang Zhengzhen. *Beijing Sports University, Beijing, China.*
 Email: 1004320180306@bsu.edu.cn
 (No relevant relationships reported)

Purpose: Heart rate product (RPP) can be used to predict cardiovascular diseases (CVD) and can be regarded as an index for continuous monitoring of ejection fraction and myocardial oxygen consumption. Exercise can improve patients' cardiovascular function and reduce the risk of having CVD. The purpose of this study was to investigate changes in heart rate (HR) and blood pressure (BP) of patients who suffer from hypertension or hypertension with diabetes mellitus during exercise and at post-exercise recovery period.

Methods: This study recruited 85 diagnosed hypertension subjects and diagnosed hypertension with diabetes mellitus subjects (40-69 years of age), who were divided into hypertension group (HTN, n = 66) and hypertension with diabetes mellitus group (HDM, n = 19). The modified Bruce protocol was adopted in this study, in which patients pedaled the cycle ergometer, starting from the level of 25W, for 3min per stage and then increasing the levels gradually. HR, BP, RPE and oxygen saturation (SPO₂) were measured at rest, during exercise and at recovery and RPP and pulse pressure difference (SBP minus DBP) were calculated.

Results: (1) The HTN group had a significantly lower resting HR than the HDM group (P<0.05, 76.12 \pm 10.73 vs 86.50 \pm 16.80 bpm, respectively). Resting RPP is significantly lower in HTN group than in HDM group (P<0.05, 88.30 \pm 26.57 vs 106.50 \pm 40.44 times \cdot mmHg/100, respectively) (2) RPP at 50W is significantly lower in the HTN group, compared with the HDM group. (P<0.05, 160.86 \pm 41.10 vs 186.68 \pm 29.86 times \cdot mmHg/100, respectively) (3) SBP at 100W (P<0.05, 186.62 \pm 17.10 vs 206.25 \pm 17.58 mmHg, respectively) and pulse pressure difference at 100W (P<0.05, 97.00 \pm 18.87 vs 127.25 \pm 25.38 mmHg, respectively) were significantly lower in HTN group. (4) The HTN

group had a significantly lower pulse pressure at the time of 5-minute post-exercise recovery than the HDM group ($P < 0.05$, 54.29 ± 15.54 vs 72.59 ± 28.71 mmHg, respectively). (5) SBP at the time of 15-minute post-exercise recovery in HTN group were significantly higher than in the HDM group ($P < 0.05$, 121.81 ± 13.70 vs 111.78 ± 8.94 mmHg, respectively).

Conclusions: The responses of heart rate and blood pressure of patients with hypertension was superior to those with hypertension with diabetes both in exercise and at post-exercise recovery period.

Effect Of Graded Exercise On Ror And Blood Oxidative-stress In Trained And Untrained Subjects

Alllan H. Goldfarb, FACSM, Kerry J. Martin, Joseph Starobin, Kirsten Ward, Ashton Dobbins, Blair Wisco. *Univ. of North Carolina Greensboro, Greensboro, NC.*
Email: ahgoldfa@uncg.edu

(No relevant relationships reported)

Submaximal graded exercise testing is a commonly used method to assess cardiovascular stress. Reserve of repolarization of the heart (RoR) is an ECG-based, non-invasive method to monitor the heart's stress response, and assesses cardiac cells ability to reestablish their membrane potential. RoR has been shown to be a useful indicator of cardiovascular disease risk in cardiac patients. This study examined RoR difference between trained (T) and untrained (U) individuals and correlate this outcome with blood stress markers. **PURPOSE:** To determine if RoR and blood stress markers in response to a graded exercise in T and U cohorts differ. **METHODS:** Thirty-nine (male and female) subjects (23.6 ± 5.6 yrs) were recruited. Subjects arrived after overnight fast between 7-9 am and rested for 20 minutes. Subjects completed a fitness questionnaire to determine training status (T or U). ECGs (12 lead) were monitored before, during and after exercise to obtain RoR. A graded walking test (GXT) on a treadmill until 85% of estimated maximum heart rate was performed. Blood obtained at rest and immediately after exercise were analyzed using HPLC for glutathione (oxidized [GSSG], reduced [GSH], total [TGSH]). Repeated measures ANOVAs were utilized to analyze the results using SPSS v24 with significance set at $\alpha = 0.05$. **RESULTS:** There were significantly lower resting HRs ($p = .023$) and higher workloads achieved during testing ($p = .002$) between T vs U groups. Resting RoR (independent of group) was significantly reduced from $75 \pm 5\%$ pre-test to $26 \pm 10\%$ RoR at the end of exercise ($p < .001$). Final stage RoR was significantly lower for T compared to U group (T: $20 \pm 9.4\%$; U: $31 \pm 9.4\%$, $p = .041$), but T group performed significantly greater stages ($p = 0.002$). The GXT induced a reduction in blood GSH (Pre 366 ± 161 μ M, Post 273 ± 180 μ M, $p < .001$) and an increase of GSSG (Pre 135 ± 62 μ M, Post 157 ± 83 μ M, $p = .038$) with no difference between groups. GSSG/TGSH decreased after GXT ($p = 0.028$) independent of group. **CONCLUSIONS:** These data suggest that a GXT induces a different stress response in T and U individuals. The oxidative stress at end GXT was similar but needed more workloads to get to this same internal stress level in the T group. Further studies are needed to ascertain stress responses with RoR and relative workloads.

Determining An Appropriate Cardiopulmonary Exercise Testing Protocol For Individuals With Neuromuscular Disease

Tina Duong, John Day, Sally Dunaway-Young, Veronica Stevens. *Stanford University, Palo Alto, CA.*
Email: trduong@stanford.edu

(No relevant relationships reported)

PURPOSE: To review published standards and recommendations for people with neuromuscular disease and establish a graded ramp-up protocol to assess exercise tolerance for individuals who have moderate to severe muscle weakness. **METHODS:** A review of literature for muscular dystrophy or neuromuscular disease and exercise testing was performed to assess different methodologies in Cardiopulmonary Exercise Testing (CPET) using cycle ergometry CPET. A progressive ramp-up protocol was developed and administered with patients who attend Stanford's multidisciplinary clinic to determine feasibility and test termination criteria that may limit the ability to achieve maximum oxygen consumption. **RESULTS:** Literature search resulted in 43 research studies. The study breakdown included Myopathies and McArdle disease =20; Pompe=5; FSHD; SMA, Metabolic Myopathies=3; DMD/BMD=2, Myotonic Dystrophy=2; CMT=1; IBM=1. Studies greatly ranged in mode of testing. Most study participants were ambulatory. Most protocols used a graded 1-2 minute progressive ramping protocol up to the point of exhaustion indicated by a Visual Analog Scale and heart rate. Early termination resulted from participants voluntarily stopping due to muscle weakness.

We developed a progressive ramp up protocol with 1-minute increment increase in workload at 5-watt intervals to avoid early termination from large increases in workload. We tested 3 individuals with neuromuscular disease and 2 controls. Only 2 participants (1 with NMD and 1 control) were able to reach an RER of 1.1 of

maximal oxygen uptake (VO₂max). Reasons for early termination were consistent with the published literature including heart rate, voluntary stop and muscle weakness. **CONCLUSIONS:** With promising treatments on the horizon for neuromuscular diseases, physical therapists are asked to determine appropriate exercise prescriptions for individuals with a range of functional abilities and muscle weakness. Currently, CPET protocol methodology varies for weaker individuals. Our results will contribute to developing a proposed submaximal clinical exercise tolerance test protocol to establish safe exercise prescriptions and determine treatment intervention benefits for patients with neuromuscular disease.

ACUTE RESPONSE OF BLOOD LIPID PROFILES TO DIFFERENT INTENSITIES OF EXERCISE IN OBESE MEN

Sophia Lillian LaMarca, Michel Hernandez, Margaret Huss, Jinkyung Park. *Georgia College and State University, Milledgeville, GA.*

Email: sophia.lamarca@bobcats.gcsu.edu

(No relevant relationships reported)

PURPOSE: This study was conducted in order to examine the blood lipid profile changes following lower or higher-intensity exercise in obese men. The changes in blood lipid profiles include TC, TG, LDL-C, HDL-C following moderate or high intensity exercise in obese males. **METHODS:** In a randomized, cross-over design, fifteen obese (BMI > 30 kg/m²) sedentary (less than 2 days per week of physical activity) male volunteers, the ages between 18 and 30 participated in the study. The participants performed a single bout of cycling exercise (average energy expenditure ~300 kcal) at two different intensities in random order [moderate-intensity: 50% of maximal heart rate and high-intensity: 80% of maximal heart rate]. Overnight fasting blood samples were collected at baseline, immediate post-exercise (IPE), 1-hr PE, and 24-hr PE for each intensity of exercise to determine blood lipids and lipoproteins (TC, TG, LDL-C, and HDL-C). A 2(intensity) X 4 (time) ANOVA with repeated measures was used to examine the mean differences in intensity and time on blood lipids and lipoproteins. The Bonferroni pairwise comparisons were conducted as post hoc to locate the significant mean differences. A p -value < .05 was set for the statistical significance. **RESULTS:** TG, LDL-C or HDL-C did not change, while TC (209.31 ± 28.89 mmol/L) at 24-hrPE decreased ($p = .041$) from IPE (217.80 ± 32.55 mmol/L) following higher-intensity exercise. However, the main effects of time ($p = .272$) or intensity ($p = .735$) demonstrated no statistically significant differences in TC. **CONCLUSIONS:** The acute higher-intensity exercise can lower TC. However, acute different intensities of exercise may not alter significantly blood lipid profiles in obese men due to the short volume and duration. Therefore, future research should determine if different intensities of chronic exercise alter blood lipid profiles in obese men.

Sleep Quality Is Associated With Habitual Physical Activity In Overweight, Older Adults

Alexandra -. Hopun, Daniel J. Canter, Melanie S. Ziazaris, Kevin D. Ballard, FACSM. *Miami University, Oxford, OH.*

(Sponsor: Kyle Timmerman, FACSM)

(No relevant relationships reported)

Poor sleep quality has been associated with negative health outcomes. This relationship has mostly been documented in middle-age and young adults with less focus on older adults. Therefore, the **PURPOSE** of this cross-sectional study was to examine relationships between sleep duration/quality with body composition, physical activity, blood lipids, and indicators of blood glucose control. **METHODS:** In 34 overweight (BMI ≥ 27 kg/m²) older adults (≥ 58 years) enrolled in a longitudinal weight-loss and exercise training study, baseline measures of body composition [skeletal muscle mass (SMM), visceral fat area (VFA) and fat mass (FM)]; cardiorespiratory fitness (VO₂max, indirect calorimetry); moderate-to-vigorous physical activity (MVPA, 7-day accelerometry); blood lipids/glucose/HbA1c (point-of-care analyzer); and sleep quality and duration (Pittsburgh Sleep Quality Index .PSQI) were assessed. PSQI scores can range from 0-21 with higher values representing lower sleep quality. Pre-intervention relationships among these variables were analyzed utilizing partial correlations, controlling for age and sex. Significance was set at $\alpha < 0.05$. **RESULTS:** Mean values were age: 64.3 ± 4.5 years; BMI: 35.3 ± 5.0 kg/m²; VFA: 217.8 ± 41.5 cm²; sleep duration: 6.8 ± 1.2 hours; PSQI score: 10.6 ± 1.3 ; VO₂max: 15.6 ± 3.8 ml/kg/min; MVPA:

45.6±22.8 min/day; HbA1c:5.5±0.5%. Sleep score was correlated with MVPA (-0.41, $p < 0.05$), but not BMI, VFA, FM, or VO2max. **CONCLUSION:** These preliminary data suggest that higher levels of MVPA were associated with better sleep quality in older adults. However, unlike previous studies, we found no relationship between indices of body composition and sleep quality. This study was supported by a grant from the National Institute on Aging (R15 AG055923-01)

 (No relevant relationships reported)

Bariatric surgery is an effective treatment option for children and adolescents with severe obesity. Yet, pediatric post-bariatric surgery (PBS) exercise recommendations are elusive. **PURPOSE:** To perform a systematic review assembling professional pediatric PBS exercise recommendations. **METHODS:** To gather PBS exercise recommendations, databases were searched from inception to 2/22/19 with terms related to exercise, pediatric obesity, bariatric surgery, and weight status. This search located no records so another PubMed search was performed to identify randomized controlled trials (RCTs), published in peer-reviewed English language journals, examining the effects of exercise on body mass index (BMI) and percent body fat (%BF) among participants 2-19yr with obesity from inception to 3/20/19. The standardized mean difference effect sizes (d_e) were calculated following random-effects models for BMI and %BF and then back-converted to the original unit for clinical interpretation. We assessed inconsistencies in d_e with the I^2 statistic transformed from the Q statistic. **RESULTS:** The second search identified 556 reports with 9 qualifying RCTs. Of these, 7 were combined resistance and aerobic and 4 aerobic interventions only. All participants ($n=342$, 53.8% girls, 13±2yr) had obesity. The moderate-to-vigorous intensity exercise interventions lasted 13.5±4.0 wk, 3.5±0.8 d/wk for 56.8±6.4 min/session. Exercise interventions ($k=11$) elicited moderate BMI reductions ($d_e=-0.40$, 95%CI: -0.73, -0.06; $-1.03\text{kg}\cdot\text{m}^{-2}$) vs non-exercise control, with moderate-to-high heterogeneity ($I^2=61.3\%$, 95%CI: 25.3, 80.0). Exercise interventions ($k=7$) also elicited moderate %BF reductions ($d_e=-0.61$, 95%CI: -0.90, -0.31; -4.63%) vs non-exercise control, with low heterogeneity ($I^2=20.5\%$, 95%CI: 0.0, 64.0). **CONCLUSIONS:** We found limited but favorable evidence of the effects of moderate-to-vigorous exercise training on BMI and %BF among children and adolescents with obesity but were unable to locate any professional pediatric PBS exercise recommendations. Due to the increasing number of pediatric bariatric surgeries performed, there is an urgent need for professional guidance on exercise in this clinical population. The Role Of Exercise In Preventing Weight Regain In Adults Post-weight Loss Surgery

Katherine M. Manuel¹, William B. Pierce², Yin Wu³, Jill Livingston⁴, Linda S. Pescatello, FACSM³. ¹Howard University, Washington, DC. ²University of Tennessee at Chattanooga, Chattanooga, TN. ³University of Connecticut, Storrs, CT. ⁴Wesleyan University of Connecticut, Middletown, CT. (Sponsor: Dr. Linda S. Pescatello, FACSM)
 (No relevant relationships reported)

The steady increase in the prevalence of obesity is reflected in the rising rate of weight loss surgeries, and repeat surgery for weight regain that occurs 1-2 yr post-weight loss surgery (PWLS). **PURPOSE:** We performed a systematic review of randomized control trials (RCTs) to determine if exercise was associated with attenuation of weight regain in adults PWLS. **METHODS:** We searched 5 databases with terms related to exercise, weight, weight regain, and weight loss surgery, and found no systematic reviews of exercise interventions ≥1yr PWLS among adults ≥18 yr, nor did we locate professional exercise guidelines for this population. We then performed a search in PubMed for randomized controlled trials (RCTs) involving exercise interventions in adults ≥18 yr PWLS. Other inclusion criteria were RCTs in peer-reviewed journals published in English, that included the frequency, intensity, type and time of the exercise intervention, and a control group receiving usual care consisting of diet and exercise advice. The standardized mean difference effect sizes (d_e) were calculated following random-effects models for body weight lost, and back-converted to the

original unit for clinical interpretation. We assessed inconsistencies in d_e with the I^2 statistic transformed from the Q statistic. **RESULTS:** The second search yielded 442 reports, with only 3 RCTs qualifying. Participants ($n=132$) were mostly white women 46.8±3.9yr, and 13.1±6.7mo PWLS. Interventions were supervised; lasted 40-60min/session, 2-5d/wk for 12-26wk; and involved moderate-to-vigorous intensity, combined aerobic and resistance training, while 1 added flexibility exercises. Compared to usual care, exercise interventions elicited moderate reductions in body weight ≥1yr PWLS ($d_e=-0.46$, 95%CI: -1.12, 0.21; -4.1kg) that did not reach significance ($p=0.069$) with high levels of heterogeneity ($I^2=62.9\%$, 95%CI: 0.0, 89.4). **CONCLUSIONS:** In a very limited literature, exercise interventions elicited clinically important reductions in weight of ~4kg representing ~4% of baseline weight ≥1yr PWLS. There is an urgent need for professional exercise guidelines and RCTs examining the effects of exercise on weight regain PWLS with larger, more diverse samples.  (No relevant relationships reported)

PURPOSE: This double-blind placebo-controlled study investigated the effects of resistance training (RT), with and without protein supplementation (PRO), on body composition, muscle strength and physical function in long term Roux-en-Y bypass (RYGB) female patients.

METHODS: A total of 45 women (age 40.4 ± 8.5 yrs, BMI 29.0 ± 4.7 kg/m²) with 4.1 ± 1.4 yrs after RYGB surgery were divided into four groups: Control + Placebo (CON+PL; $n = 11$), Control + PRO (CON+PRO; $n = 10$), RT+PL ($n = 12$), and RT+PRO ($n = 12$). Patients were evaluated before and after the 12-weeks study protocol for body composition (Tetrapolar Bioelectrical Impedance), knee extensors isokinetic strength and physical function (timed up and go [TUG], 30-seconds sit to stand, and 6-minutes walking). PRO and PL were administered in a double-blind fashion and respectively consisted of daily 0.5 g of whey protein powder per kg of ideal body weight and an isocaloric placebo powder, both throughout the study period. Training protocol comprised 3 sets of 8-12 reps for 8 exercises targeting all major muscle groups and with progressive loads. ANOVA was used to assess time by group interactions.

RESULTS: No significant between-groups differences were observed for any variable at baseline (all $P > .05$). Significant improvements were observed in the exercised groups, but not in the nonexercised groups, for skeletal muscle mass (RT+PL 0.6 ± 0.3, $P = .02$; RT+PRO 0.8 ± 0.2, $P < .01$; CON+PL -0.1 ± 0.3, $P = .68$; and CON+PRO 0.3 ± 0.3 kgs, $P = .31$), isokinetic peak torque (RT+PL 12.9 ± 3.1, $P < .01$; RT+PRO 8.7 ± 2.6, $P < .01$; CON+PL -4.4 ± 2.9, $P = .15$; and CON+PRO -3.1 ± 2.9 Nm, $P = .30$), TUG (RT+PL -1.1 ± 0.2, $P < .01$; RT+PRO -0.7 ± 0.2, $P < .01$; CON+PL -0.2 ± 0.2, $P = .38$; and CON+PRO -0.3 ± 0.2 seconds, $P = .23$), six-minutes walking (RT+PL 48.4 ± 20.6, $P = .02$; RT+PRO 37.4 ± 17.8, $P = .04$; CON+PL -0.9 ± 21.9, $P = .97$; and 4.4 ± 19.5 meters, $P = .82$) and seat to stand test (RT+PL 3.2±0.7, $P < .01$; RT+PRO 1.7±0.6, $P < .01$; CON+PL 1.1±0.7, $P = .13$; and CON+PRO 0.7 ± 0.6 repetitions, $P = .25$). No differences for the improvements were observed between exercised groups (all $P > .05$). Also, no significant alteration occurred for percent body fat in any group (all $P > .05$).

CONCLUSIONS: A 12-weeks RT program, regardless of PRO, improves muscle mass, knee extensors isokinetic strength and physical function in long term RYGB female patients.

Obesity epidemic is a complex and multifactorial chronic condition affecting one in three adults globally while it is associated with high metabolic risk factors enhancing chronic illness. On the other hand, high-intensity interval training (HIIT), group training, body weight training, and functional fitness training have been recently reported as some of the top worldwide trends in the health and fitness industry. **PURPOSE:** This randomized controlled trial investigated the effects of a 5-month high-intensity interval-type neuromuscular training program (DoIT) with adjunct portable modalities on cardiometabolic health in previously inactive obese women. **METHODS:** Forty-nine premenopausal Caucasian obese female volunteers (n = 49; 36.4 ± 4.4 years; 29.1 ± 2.9 kg/m²; 46.8 ± 5.0% body fat; 0.87 waist-to-hip ratio) were randomly assigned to control group (C, n = 21) or to training group (TR, n = 28). The exercise protocol was a supervised, low-volume, progressive, and time-efficient (<30 min) training program incorporating HIIT and functional fitness into a real-world gym setting. Neuromotor exercises (10-12 integrated movements) with alternate portable modalities at prescribed work-to-rest intervals (20-40 sec) in a circuit fashion (2-3 rounds) were implemented on nonconsecutive days for 5 months. Blood samples were drawn to determine cardiometabolic risk factors at pre- and post-training. **RESULTS:** After 20 weeks, TR demonstrated changes in waist circumference (-6.6%, p < 0.05; TR vs. C: -6.3%, p < 0.05), total cholesterol/high-density lipoprotein ratio (-14.1%, p < 0.05; TR vs. C: -17%, p < 0.05), mean arterial blood pressure (-4.1%, p < 0.05; TR vs. C: -4.6%, p < 0.05), and metabolic syndrome severity z score (-327%, p < 0.05; TR vs. C: -283%, p < 0.05). No change in homeostasis model assessment of insulin resistance (HOMA-IR) was observed from pre- to post-intervention in both groups, whereas HOMA-IR did not differ between groups at any time-point. **CONCLUSIONS:** These findings suggest that high-intensity interval neuromuscular training may improve cardiometabolic health in previously inactive obese women following a 20-week intervention. This study provides critical evidence for implementation of this nontraditional hybrid-type exercise regimen from adults with obesity into a real-world gym setting.

Muscle wasting observed in obese women undergoing bariatric surgery is likely related to altered abnormal intramyocellular signaling. Exercise may reestablish the anabolic capacity in this condition. **PURPOSE:** We examined the effects of exercise training on the main pathways related to skeletal muscle plasticity in obese women undergoing bariatric surgery. **METHODS:** Women with severe obesity were randomly allocated to either bariatric surgery (RYGB) or bariatric surgery followed by exercise (RYGB+ET). A 6-month, three-times-a-week, supervised, combined aerobic and resistance training program started 3 months after surgery for RYGB+ET, while RYGB followed standard of care. We assessed the transcriptome (RNA-seq) from skeletal muscle samples obtained by muscle biopsies (n = 6 per group) at baseline (PRE) and 9 months after surgery (POST9). We tested whether a set of genes defined *a priori* were differentially expressed utilizing the Gene Set Enrichment Analysis. Significance was assumed at a fold change > 1.5, P-value < 0.05, and FDR (false discovery rate) < 0.1. To validate the RNA-seq findings, we performed real time-polymerase chain reaction assays (n = 15 per group) for targeted genes. **RESULTS:** Pathway-level analysis showed that exercise significantly suppressed ubiquitin mediated proteolysis pathway (normalized enrichment scores [NES]: 1.7, P=0.01, FDR=0.09). *Atrogin-1* gene expression was suppressed in the exercised group at POST9 in comparison to PRE, and POST3,

and also when compared with the non-exercised group at POST9 (estimated mean difference [RYGB vs. RYGB+ET at POST9]: -1.97, CI95%=-3.0 to -0.8, P=0.01). *MuRF-1* gene expression decreased after surgery and kept reduced after the intervention for both groups (main time effect: P<0.01 for both). **CONCLUSIONS:** Our data suggest that a 6-month, exercise training program suppresses the ubiquitin-proteasome system via the downregulation of *Atrogin-1* in obese woman undergoing bariatric surgery. This may elucidate a molecular mechanism that partially explains muscle wasting following bariatric surgery and the exercise-induced hypertrophic effect in this condition. Clinicaltrials.gov: NCT02441361

 (No relevant relationships reported)

Many body composition devices now provide an estimate of visceral adipose tissue (VAT), a significant risk factor for cardiometabolic disease. **PURPOSE:** To evaluate the relationship between estimates of VAT from bioelectrical impedance (BIA), ultrasound (US), and dual-energy x-ray absorptiometry (DXA). **METHODS:** VAT was estimated in 124 adults (66% Female; Mean ± SD: Age: 25.4±8.9 yrs; BMI: 25.4±5.5 kg·m⁻²; %BF: 29.7±10.5%). VAT area (cm²) was estimated from a BIA system specific algorithm. VAT thickness (cm) was estimated using US, quantified as the distance between the linea alba and aorta. VAT volume (cm³) was estimated from the DXA predefined android region. Linear regression was used to evaluate the relationship between estimates and to identify factors that may contribute to estimate differences in the entire group and by sex. **RESULTS:** In the full group, VAT estimates from all three methods were significantly correlated [BIA-DXA (R=0.768; R²=0.589); BIA-US (R=0.545; R²=0.297); DXA-US (R=0.785; R²=0.616) (p<0.001)]. In men, stronger relationships were observed with DXA [BIA-DXA (R=0.852; R²=0.727); BIA-US (R=0.774; R²=0.600); DXA-US (R=0.878; R²=0.772) (p<0.001)]; in women, weaker relationships were observed with US [BIA-DXA (R=0.890; R²=0.793); BIA-US (R=0.567; R²=0.321); DXA-US (R=0.690; R²=0.477) (p<0.001)]. In men, total body water (TBW) explained 31.9% and 12.0% of the variance in the difference between BIA-DXA and BIA-US, respectively; %BF explained 13.1% of the variance in the difference between DXA-US (all p<0.05). In women, %BF explained 28.9%, 34.0%, and 15.6% of the variance in the difference between BIA-DXA, BIA-US, and DXA-US, respectively (all p<0.001). **CONCLUSIONS:** BIA and US are cost-effective alternatives to DXA. BIA may provide a more comparable estimate to DXA, while greater variability may occur when comparing with US, especially in women. Differences between estimates may be influenced by TBW and %BF.

 (No relevant relationships reported)

Inter-individual variation in response to exercise training (ET) is broad and can lead to individuals, termed 'non-responders', who do not experience the anticipated improvements. The inter-individual variation in cardiometabolic response to ET among overweight and obese youth and prevalence of non-responders is poorly understood. **Purpose:** To investigate inter-individual variation following 6-months of high-intensity or moderate-intensity ET, and estimate the proportion of overweight and obese youth expected to respond. **Methods:** One hundred and six overweight and obese youth were randomized to high-intensity ET (70–85% of heart rate reserve), moderate-intensity ET (40–55% heart rate reserve), or a control group for 6 months. Cardiometabolic response to ET was assessed by insulin sensitivity (IVGTT), hepatic triglyceride content (¹H-MRS), visceral adipose tissue (MRI), and cardiorespiratory fitness. Participants with ≥70% adherence were included in this secondary analysis. Inter-individual variation within each study arm was determined using the standard deviation of individual responses (SD_{IR}), calculated as: SD_{IR} = √(SD_{Intervention}² - SD_{Control}²). The proportion of responders (defined as a change surpassing the smallest worthwhile difference) to each program was estimated using the variance (SD_{IR}) around the mean treatment effect. **Results:** Inter-individual variation resulting from high-intensity ET was observed in visceral adipose tissue (SD_{IR} = 5.92) and cardiorespiratory fitness (SD_{IR} = 1.33), with

51.2% and 79.1% of overweight and obese youth estimated to respond. Inter-individual variation resulting from moderate-intensity ET was observed in hepatic triglyceride content ($SD_{tr} = 9.64$) and cardiorespiratory fitness ($SD_{tr} = 2.15$), with 34.3% and 71.8% of overweight and obese youth estimated to respond. Inter-individual variability was not detected among changes in insulin sensitivity following either program. **Conclusion:** These data support the concept of inter-individual variation in cardiometabolic health outcomes following high- and moderate-intensity ET in overweight and obese youth. High-intensity ET was estimated to produce a higher proportion of cardiorespiratory fitness responders compared to moderate-intensity ET.

2379 Board #298 May 28 3:00 PM - 4:30 PM
Effects Of High-Intensity Interval Training On Cardiometabolic Risk Factors And Motivation To Exercise In Women With Abdominal Obesity

Patricia Blackburn, Bruno Martel, Maxime St-Pierre, Claudie Émond, Jacques Plouffe. *Université du Québec à Chicoutimi, Saguenay, QC, Canada.*
(No relevant relationships reported)

There has been recent interest in high-intensity interval training (HIIT) as an alternative to moderate-intensity continuous training (MICT) to reduce body composition, adiposity and cardiometabolic risk factors in obese patients. Despite the promising evidence supporting HIIT in this population, there is limited research targeting women with abdominal obesity. **PURPOSE:** The objective of this study was to compare the effects of MICT and energy-matched HIIT on cardiometabolic risk factors in women characterized by abdominal obesity. **METHODS:** Twenty abdominally obese women (age range, 28-56 years) were submitted to 12 weeks of intervention and were randomly allocated into 2 groups: MICT (n=10) and HIIT (n=10). The MICT group performed a 38 to 62-minute continuous exercise at 70 % of the maximal heart rate. The HIIT group training performed 3 to 6 sets of 4-minute bouts at a running velocity corresponding to 90 % maximal heart rate, interspersed by a 4-min active recovery period at 50 % maximal heart rate. Anthropometric parameters, maximal oxygen uptake (VO_{2max}) and cardiometabolic risk variables were measured at the beginning and after 12 weeks. Self-determined motivation toward physical activity was also evaluated with a validated questionnaire. **RESULTS:** MICT intervention led to significant improvements in VO_{2max} (29.9 to 32.7 ml $O_2 \cdot kg^{-1} \cdot min^{-1}$, $p=0.005$), with no change in HIIT group. However, at the beginning of the study, VO_{2max} was significantly lower in the MICT group when compared to the HIIT group ($p=0.04$). During the intervention, no significant difference was found in cardiometabolic risk factors in the MICT group. However, HIIT resulted in statistically significant reduction in triglycerides levels (1.91 to 1.58 mmol/l, $p=0.046$) even though waist circumference was significantly increased (98.0 to 100.7 cm, $p=0.038$) after the 12-week intervention program. In addition, the HIIT group increased self-determined motivation toward physical activity in a greater magnitude when compared with the MICT group ($p=0.016$). **CONCLUSION:** HIIT appears to provide greater benefits to MICT for improving triglyceride levels. In addition, as HIIT is associated with a greater improvement in self-determined motivation toward physical activity, HIIT could be associated with promising long-term adherence to exercise.

Intensive Behavioral Therapy For Obesity Utilizing Cardiopulmonary Exercise Testing: The Bridge Project Pilot Study.

Matthew Kampert, Debasis Sahoo. *Cleveland Clinic, Cleveland, OH.*
 Email: mkampert1@gmail.com
(No relevant relationships reported)

PURPOSE: To gather preliminary pilot data on dietary and exercise prescription utilizing Cardiopulmonary Exercise Testing (CPET) incorporated into Medicare and Medicaid Services-based Intensive Behavioral Therapy for Obesity (IBT-O) in a primary care setting. **METHODS:** A prospective cohort of 30 subjects completed a World Health Organization Quality of Life (WHOQOL) questionnaire, and performed a cardiopulmonary exercise test (CPET) on a treadmill using a modified Balke protocol at baseline as well as following 6 and 12 months of exercise conditioning. With a cardiovascular exercise prescription developed from CPET data delivered to the subjects' Smartphone through an interactive app. Subjects were also provided with a resistance training prescription and YMCA membership. Consistent with CMS criteria,

subjects participated in weekly physician directed IBT-O appointments throughout the first month, and then bi weekly for the next 5 months. If subjects lost 6.6 lbs (3 kg) in the initial 26 weeks (6 months) they qualified to continued physician once a month for an additional 6 months. **RESULTS:** With the 30 subjects initially enrolled, there were 9 enrollment failures. There was an overall follow up rate of 76% of the 21 successfully enrolled, with 19 completing all 6 months. At the 6 months, 14 subjects lost 6.6lbs required by CMS to continue for an additional 6 months, and 11 completing all of the 12 months. Data reported in table using mean \pm standard deviations for all continuous variables. All analyses were two-tailed and were performed at a significance level of 0.05.

CONCLUSIONS: In addition to improvements in QOL and clinically meaningful weight loss >5% at 12 months, there was also an increase CRF. Improvements in CRF has been reported in the literature with annual cost savings per MET/year of \$5,193 and \$3,603 for individuals with and without diabetes, respectively. Also, increases of 1-2 METs are associated with 10%-30% lower adverse cardiovascular event rates.

Do Different Wet Bulb Globe Temperature Reading Cutoffs Change Outdoor Heat Injury Frequency And Severity?

Christina S. Gutta¹, Ellen E. Shanley², Vicki R. Nelson¹. ¹*Prisma Health, Greenville, SC.* ²*ATI Physical Therapy, Greenville, SC.*
 (Sponsor: Dr. Franklin Sease, FACSM)
(No relevant relationships reported)

PURPOSE: To evaluate differences in injury frequency and severity between two different heat participation policies in South Carolina high school and collegiate athletics.

METHODS: Retrospective cohort study of Division II collegiate & high school athletes looking at injury frequency & severity between 2 different heat participation policies. Fifty middle & high schools as well as 2 Division II colleges with a total of 16,832 athletes were investigated over 3 years. Inclusion criteria were reported heat illnesses between July 1 & November 30th for 12 outdoor sports resulting in 86 injuries that were analyzed. Chi square analysis was used to compare injury frequency & severity between no outdoor workouts with a wet bulb globe temperature (WBGT) > 90 (policy 1) versus WBGT > 92 (policy 2).

RESULTS: For policy 1 there was a mean of 31 heat illnesses/year with an average of 16 days for illness resolution. For policy 2 there was a mean of 24 heat illnesses/year but the average of 41 days for illness resolution was significantly higher ($p=0.02$). Grading heat illness severity was based on guidelines developed by Rauh et. al. Mild to moderate injury was defined as 0-21 days for return to activity while severe injury >21 days for return to activity. With policy 1, 4.8% of heat illnesses met severe criteria while 20.8% of heat illnesses in policy 2 were severe showing an odds ratio of heat illness with policy 2 is 5.2 times higher than policy 1 (OR 5.2, 95% CI 1.1-23.7). Conversely the percentage of mild to moderate illness was statistically lower with policy 2 compared to policy 1 ($p=0.022$) suggesting that policy 2 resulted in more severe heat illness. Policy 1 was in place for several years with no record of EMS transport for heat illnesses however within the first season of policy 2, there was 3 athletes transported. The average age at time of injury was 16 years old & not statistically different between policies. There was an average of 45 minutes of practice per week lost with the WBGT cutoff of 90 compared to cutoff of 92.

CONCLUSIONS: Although the total number of heat illnesses did not change between policies, there was a statistically significant increase in severity of illness & time for return to sport with raising the WBGT participation cutoff from 90 to 92. Our data suggests that a cutoff of 90 reduces the frequency of severe heat illness in athletes.

Differences In Baseline Concussion Symptom Reporting Across Age And Gender
 Joshua Pacious, Franklin Sease, FACSM, Vicki Nelson. *Prisma Health- Center for Family Medicine, GREENVILLE, SC.*
(No relevant relationships reported)

Purpose:

Previous studies have identified significant differences across age and gender in post-concussion symptoms reporting, with female and high school aged athletes reporting both a higher number of symptoms and a greater symptom severity. This study evaluates differences in baseline symptom reporting across age group and gender.

Methods and Study Design:

Between 2007-2019, concussive symptoms were reported by middle school (MS), high school (HS) and collegiate athletes (CA) utilizing the post-concussion symptom scale at baseline. Excluded athletes included those with invalid testing, age > 24y or < 10y, learning disabilities, ADHD, autism, or a prior history of concussion. ANOVA was performed assessing the total number of symptoms and the total symptom severity score as reported by age group, and gender. Results: (1000)25,694 athletes (60% male and 40% female) were included: 4.6% MS (n=1,179), 89.7% HS (n=23,047) and 5.7% CA (n=1,468). Among the different age groups, there were no significant differences in number of symptoms (p=0.21) or symptom severity score (p=0.48). However, there were significant differences noted between male and female athletes. Males reported fewer symptoms than females (1.75 ± 3.0 vs 2.50 ± 3.6, p<1x10⁻⁷⁰). Males also reported a lower baseline symptom severity (3.34 ± 6.7 vs 4.96 ± 8.7, p<1x10⁻⁶²). This difference between genders held true across age levels with significant differences in the number of baseline symptoms reported (MS p<0.001, HS p<1x10⁻⁶⁰, CA p<0.001) and symptom severity score (MS p<0.001, HS p<1x10⁻⁵¹, CA p<0.01).

Conclusion: This study identifies symptom differences between genders at baseline. These baseline differences may contribute to the post-concussive discrepancies seen previously. In contrast, baseline differences are not present between age groups possibly suggesting a pathophysiologic underpinning to the post-concussive discrepancies of higher total symptoms and higher severity noted in high school athletes.

Significance of Findings: Significant differences in concussive symptom reporting by age level, despite comparable baselines shown here, may reflect pathophysiologic, rather than reporting discrepancies, necessitating specific evaluation and management strategies across age levels.

2383 Board #302 May. 28 3:00 PM - 4:30 PM
Assessing Knowledge And Confidence In Musculoskeletal Medicine Among Primary Care Specialties
 Jessica Mofidi, Cindy Ong, Michael Fong, Marissa Vasquez. *Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA.* (Sponsor: Aaron Rubin MD, FACSM)
(No relevant relationships reported)

Prior studies suggest primary care clinicians lack knowledge and confidence in how to diagnose and treat musculoskeletal (MSK) disorders. One showed 64% of academic primary care attendings scored <70% on an MSK knowledge exam, while another noted that primary care residents scored an average of 56% on an MSK competency exam. Few studies examine differences among Family Medicine, Internal Medicine, and Pediatrics in knowledge and confidence in diagnosing and treating MSK conditions. **Purpose:** To determine if a significant difference exists between primary care specialties for both residents and non-fellowship trained attendings in knowledge and confidence in diagnosing MSK conditions. To assess whether a focused lecture series can increase resident knowledge and confidence in diagnosing MSK disorders. **Methods:** An anonymous shoulder, hip, knee, and ankle survey was emailed to Pediatric, Internal Medicine, and Family Medicine residents and attendings at a local teaching hospital. Sports Medicine Fellows lectured Internal Medicine and Pediatrics residents, focusing on exam and common conditions for each joint. Family Medicine was excluded from the lectures, as MSK education is a part of their ACGME requirement. Pre and post lecture surveys with 5 knowledge questions and two 5-point Likert scale confidence measures were administered to Pediatric and Internal Medicine residents. Two-tailed t-tests were used with a p value set at <0.05. **Results:** Pediatric residents showed a significant increase in shoulder knowledge scores (60% vs 72.8%, p=0.04), shoulder confidence scores (2.2 vs. 3.11; 2.13 vs. 2.94; p<0.001), and confidence in doing an appropriate knee exam post lecture (2.6 vs. 3.4, p=0.03). There was no significant difference between Family Medicine, Internal Medicine, or Pediatrics regarding general MSK knowledge and confidence. There was no significant difference for Internal Medicine between pre and post lecture scores for all joints. There was no significant difference for pre and post lecture scores on the hip and ankle for Pediatrics. **Conclusion:** Dedicated lectures related to the MSK exam and common MSK conditions can increase the knowledge and confidence among primary care residents, but further studies with a greater number of subjects are needed.

2384 Board #303 May. 28 3:00 PM - 4:30 PM
Documentation Of Obesity On The Problem List And Referral Rates Among Obese Children And Adults
 Heidi Walls, Christina Holt, Amy Haskins, William Dexter, FACSM. *Maine Medical Center, Portland, ME.*
(No relevant relationships reported)

Obesity is a serious public health concern that is overwhelming primary care providers. Studies have shown that simply documenting obesity on the problem list promotes action about obesity. **PURPOSE:** To determine the rate of obesity documentation on the problem list and referrals to obesity medicine specialists and dietitians among obese adult and pediatric patients at 14 primary care offices in a regional health network in Southern Maine. **METHODS:** All patients with BMI > 30 (adults) or BMI > 95th percentile for age (pediatrics) between 5 - 100 years old, who were seen at one of 14 primary care clinics in Maine between July 1, 2017 and June 30, 2019 were included for retrospective review. Variables requested included age, BMI, inclusion of obesity on the problem list, various comorbidities, and any referrals to dietitian or obesity medicine specialists. The percentage rate of inclusion of obesity on the problem list and rate of referrals were calculated for both pediatric and adult patients.

RESULTS: We obtained records for 20,461 patients, 2,780 under 18 and 17,681 over 18. Obese children had obesity on the problem list in 31.2% of cases, and received any referral 12.5%. Obese adults had obesity on the problem list 54.2% of the time, and a referral in 8.4% of cases. For both children and adults, more referrals were made for patients with obesity on the problem list compared to those without this problem listed (in children: 20.2% vs 9.0%; for adults: 12.12% vs 3.9%, p values < 0.0001). Similarly, a statistically significant higher proportion of referrals were made for those with higher BMI (in children: 26.6% vs 8.6% for those with a BMI ≥ 99 percentile; adults: 19.88% vs 5.75% for those with a BMI ≥ 40, p values < 0.0001), and for those with a greater number of comorbidities on the problem list (referrals in 20.2% vs 10.7% for children with ≥ 1 comorbidity vs 1 or fewer, and in 22.68% vs 5.13% of adults with ≥ 3 comorbidities compared to 0 comorbidities, p values < 0.0001).

CONCLUSIONS: The inclusion rate of obesity on the problem list for obese children and adults was found to be low overall, but inclusion was associated with higher proportion of referrals to obesity medicine specialists and dietitians. There was also more likely to be a referral among patients with higher BMI and multiple comorbidities.

2385 Board #304 May. 28 3:00 PM - 4:30 PM
Improving The Diagnosis Of Menstrual Dysfunction Through Quality Improvement
 Kayla E. Daniel, Amy Valasek. *Nationwide Children's Hospital, Columbus, OH.* (Sponsor: Anastasia Fischer, FACSM)
 Email: Kayla.Daniel@nationwidechildrens.org
(No relevant relationships reported)

PURPOSE: Prevalence of menstrual dysfunction in female high school athletes ranges from 19-54%. Menstrual dysfunction can be screened and treated. Consequences of menstrual dysfunction include decreased bone mass, increased risk of stress fractures, increased rate of musculoskeletal injuries with prolonged recovery time, endothelial dysfunction, and effects on future fertility. Early recognition and intervention are crucial to prevent long term consequences. The purpose of this Quality Improvement (QI) project is to optimize the institution's Epic Best Practice Advisory (BPA) screening tool and synthesize new patient questionnaire responses to diagnose menstrual dysfunction in female athletes greater than 12 years of age presenting to a pediatric sports medicine clinic.

METHODS: Using QI methodology, we evaluated the clinic work flow, Epic BPA tool, and actions by the physician following appropriate firing of the menstrual dysfunction BPA. Menstrual dysfunction was defined in our BPA as criteria for Amenorrhea, Oligomenorrhea, or Irregular Menstruation Unspecified which was further specified as menstrual cycles effected by training in sport. Staff education, patient education, and BPA provider alert fatigue were identified as appropriate areas for intervention. Staff were educated to ensure appropriate intake and implementation of survey data, a menstrual dysfunction handout was created and provided to newly diagnosed patients, and the BPA alert was changed to promote identification and diagnosis of menstrual dysfunction. We implemented interventions using progressive monthly Plan-Do-Study-Act (PDSA) cycles to encourage change and optimize our screening process.

RESULTS: The rate of appropriate diagnosis of menstrual dysfunction in female athletes greater than 12 years of age seen at a pediatric sports medicine clinic increased from a baseline of 1.5% to 27% over a 3-month period.

CONCLUSIONS: Through QI methodology we are optimizing our menstrual dysfunction screening tool and subsequently increasing the rate of appropriate diagnosis of menstrual dysfunction among our female athletes. Identifying the appropriate diagnosis improves patient education and provides the framework for applicable interventions, further work-up, and follow-up.

2386 Board #305 May. 28 3:00 PM - 4:30 PM
Injury Trends In Special Olympics Athletes From The 2018 USA Games

Bram Newman¹, Jessie Fudge, FACSM², Amy Haskins¹, Christina Holt¹, William Dexter, FACSM¹. ¹Maine Medical Center, Portland, ME. ²Everett Medical Center, Everett, WA. (No relevant relationships reported)

Purpose: We analyzed injury data from the Seattle Special Olympics USA Games 2018. Our findings and analysis may inform ways by which medical coverage at future similar events can be reinforced, prepared, and improved.

Methods: Deidentified injury data, collected by the RaceSafe app, was categorized by injury type: Musculoskeletal (MSK), Non-musculoskeletal (Non-MSK) and Minor Injury (including ice, bandaging, and massage). Individual event data was analyzed by percent of athletes injured and by injuries per 1000 athlete exposures. For each team sport, injury data was analyzed by injuries per game.

Results: The individual events with the highest percent of athletes injured were gymnastics (38.5%, 95% CI 22.4-62.0), tennis (31.5, 95% CI 21.5-44.7) and stand-up paddleboard (28.6%, 95% CI 11.6-59.4). The individual event with the lowest percent of athletes injured was golf (12.9%, 7.9-19.9). Among the gymnastics and tennis injuries, 53.3% and 58.6% were MSK, respectively. For stand-up paddleboard there were no MSK injuries with the majority being non-MSK (66.7%). Per 1000 athlete exposures, gymnastics had the highest rate of MSK injuries at 25.6 (95% CI 11.9-48.7), while stand-up paddleboard had the highest rate of both non-MSK injuries at 95.2 (95% CI 30.3-23.0) and minor injuries at 47.6 (95% CI 8.0-157.3). The team sports with the highest rate of injuries per game were softball at 1.9 (95% CI 1.6-2.4), followed by soccer at 1.7 (95% CI 1.4-2.0), and flag football at 1.6 (95% CI 1.3-1.9).

Conclusion: The Special Olympics 2018 USA Games required a well-staffed and organized medical team to meet the injury needs of its athletes. Based on our analysis, future events should provide a team with many medical personnel divided amongst the competition venues. A unique feature of the Special Olympics is the high rates of non-MSK injuries requiring medical attention, and appropriate measures should be taken to address these conditions.

2387 Board #306 May. 28 3:00 PM - 4:30 PM
The Use Of Micro-doppler Radar For Motion Analysis In NCAA Athletes

Joseph Andrie¹, Cayce Onks¹, Donald Hall², Tyler Ridder², Zacharie Idriss², Ram Narayanan². ¹Penn State Health, Hershey, PA. ²Penn State University, University Park, PA. (No relevant relationships reported)

PURPOSE: The current musculoskeletal portion of the pre-participation physical exam lacks evidence for the detection of biomechanical subtleties that predispose an athlete to injury. Previous pilot data has shown that micro-Doppler radar has the potential to provide objective data on limb and torso variations at a granular level using a handheld, portable and cost effective device. The purpose of this study was to determine if micro-Doppler radar signals can predictably and accurately detect subtle differences in human movement patterns.

METHODS: This is a cross sectional study using micro-Doppler radar technology to detect known differences in biomechanics among Division III athletes. Each participant performed 3 sets of 3 squat jumps in front of the micro-Doppler radar antenna. Each set of squat jumps was performed barefoot, with shoes and with a 2cm heel lift at both 0 degrees and turned 90 degrees to the antenna. The micro-Doppler responses were processed using short-time Fourier transform, principal component analysis and linear discriminant analysis to highlight differences among the data sets and to minimize background noise from the radar. Further computer learning classification using support vector machine, k-nearest neighbor and discriminant analysis classifier were used to determine the micro-Doppler radar accuracy for predicting movement patterns.

RESULTS: Thirty seven NCAA Division 3 Football athletes aged 18-22 were recruited and consented to perform the protocol. All micro-Doppler radar responses were recorded and processed successfully. The overall accuracy of the computer-derived models to predict which participants were wearing shoes, a heel lift or barefoot was 83%-100% for all groups regardless of whether the athlete was facing or turned to the right of the radar. **CONCLUSIONS:** This study was able to demonstrate that micro-Doppler radar technology has excellent predictability and can accurately detect subtle differences in movement. Future studies will aim to further validate data sets using comparison studies to biomechanical video analysis techniques. Ultimately the goal will be to use the micro-Doppler radar to define movement patterns that may predispose athletes to injury allowing us to determine a high risk group to direct injury prevention resources.

2388 Board #307 May. 28 2:00 PM - 3:30 PM
Comparison Of Ultrasonography To Mri In The Diagnosis Of Lower Extremity Bone Stress Injuries.

Kevin Mullins¹, Lauren Bosshardt¹, Sara Raiser², Richard Lawley³, Yaeko Fukushima¹, Isaac Syrop⁴, Jeremiah Ray⁵, Andrea Finlay⁶. ¹Stanford University, Redwood City, CA. ²Emory University, Johns Creek, GA. ³Cornerstone Orthopaedics, Superior, CO. ⁴Columbia University, Tarrytown, NY. ⁵University of California, Davis, Davis, CA. ⁶Stanford University, Stanford, CA. (Sponsor: Michael Frederickson, MD, FACSM) Email: kevinmullinsmd@gmail.com (No relevant relationships reported)

BACKGROUND: Bone-stress injuries (BSIs) are relatively common in college-level athletes and can result in substantial disability leading to prolonged leave from sport when diagnosed in more advanced stages. Early detection and intervention of BSIs in this population is critical given the demanding NCAA schedules and expectations for timely returns to full activity. Currently, the gold standard for detecting early-stage BSIs is magnetic resonance imaging (MRI), however with recent global advancements in ultrasound technology, there are new opportunities for early diagnosis of BSIs in the sports medicine clinic and training-room settings.

PURPOSE: To examine the sensitivity and specificity of ultrasound imaging (USI) in the diagnosis of BSIs, utilizing MRI as the gold standard.

STUDY DESIGN: Cohort Study (diagnosis)

METHODS: Thirty-nine elite primarily NCAA division 1 athletes (mean age, 21.64 years; standard deviation [SD], 7.24; range 18-62) underwent USI and MRI for clinical suspicion of a BSI in the lower extremity. 32 females and 7 males enrolled, with running as the most common sport (44%). An 8-point assessment system was utilized on USI for detecting BSI, and the Frederickson Criteria was used to classify MRI findings. Sensitivity, specificity, positive and negative predictive values (PPV and NPV) of USI compared to MRI were calculated.

RESULTS: Using MRI, there were 31 (79%) athletes with a positive and 8 participants with a negative BSI diagnosis. The most common bone injuries were metatarsal (51%) and tibia (33%). Average days to onset was 31.87 (SD = 34.20). Compared to MRI, USI demonstrated 0.77 sensitivity (95% confidence interval [CI], 0.59-0.90) and 0.75 specificity (95% CI, 0.35-0.97) in detecting BSI, with a PPV of 0.92 (95% CI, 0.75-0.99) and NPV of 0.46 (95% CI, 0.19-0.75). Subcutaneous edema was the most sensitive (0.81, 95% CI=0.63-0.93) USI finding but the least specific (0.25, 95% CI=0.03-0.65), while calcified bone callus was the most specific (0.88, 95% CI=0.47-1.00) but least sensitive (0.26, 95% CI=0.12-0.45).

CONCLUSION: USI is a reliable screening tool for sports medicine providers to combine with their clinical evaluation in the diagnosis of bone stress injuries. Further research is ongoing to determine the role of USI in follow-up care and return-to-play protocols.

2389 Board #308 May. 28 3:00 PM - 4:30 PM
Does Poor Recovery Predict Injury In The Division 1 Female Collegiate Lacrosse Athlete?

Jeffrey Wisinski, Paul Herickhoff, Brandon Hall, Peter Seidenberg, FACSM. ¹Penn State University, University Park, PA. (Sponsor: Peter Seidenberg, FACSM) Email: jwisinski@pennstatehealth.psu.edu (No relevant relationships reported)

BACKGROUND: Overtraining continues to be a serious issue across youth athletes at all levels. As an athlete transitions to the collegiate level, their training volume typically increases significantly. With more female athletes participating in Collegiate Lacrosse, there needs to be an ongoing awareness of athletes at increased risk for overuse and acute injuries. Examining injury incidence patterns and attempting to objectively find risk factors for the development of these injuries can provide helpful feedback to coaches, athletic trainers, and team physicians when determining athlete participation recommendations.

PURPOSE: Retrospectively analyze data related to the recovery of 31 Division 1 Collegiate Female Lacrosse athletes obtained over an entire regular season, and then determine if athletes who suffered injuries had lower recovery scores in comparison to athletes who did not suffer injuries.

METHODS: The data related to the recovery of the Collegiate Female Lacrosse athletes was obtained using a questionnaire developed through the Restwise division of Recovery Science and Technology. An overall Recovery score was calculated based on the athlete's heart rate, weight, pulse oximetry, and their responses to questions about quality and amount of sleep, energy level, presence of illness, and mood state. Athletes submitted their respective responses using the online Restwise application prior to each practice and game. Injury reports were then analyzed to determine specific dates of injuries. A logistic regression analysis was performed to determine if there was a statistically significant association between overall recovery scores as well as the specific components of overall recovery scores, and future injury.

RESULTS: 21 total injuries took place throughout the regular season. Overall recovery scores were not shown to be associated with future injury ($p = 0.518$). Previous injury ($p = 0.118$), illness ($p = 0.48$), mood ($p = 0.588$), amount of sleep ($p = 0.648$), sleep quality ($p = 0.686$), and energy state ($p = 0.211$) were also not shown to have a statistically significant relationship with future injury.

CONCLUSION: Restwise Recovery Data was not shown to have a statistically significant association with future injury in the Division 1 Female Lacrosse Athlete.

2390 Board #309 May. 28 3:00 PM - 4:30 PM

The Effect Of Social Media Use On Sleep Quality Among College Athletes

Rhonda Watkins, Dai Sugimoto, Danielle Hunt, Jeesie Oldham, Andrea Stracciolini, FACSM. *Boston Children's Hospital, Boston, MA.*

(No relevant relationships reported)

BACKGROUND: Social media use among young adults has increased significantly in recent years. Existing literature suggests that increased social media use is linked to poor sleep quality, but this is unexplored in college athletes, who pose a unique risk for poor sleep given academic, social, and sport demands. **PURPOSE:** 1) To examine the effect of social media use on sleep quality among college athletes. 2) To compare the effect of social media use on sleep quality by sex. **METHODS:** Study participants included local NCAA Division III college athletes. Across sectional study design was employed. Data was collected using social media use and PROMIS sleep disturbance questionnaires. Main outcome measures were social media volume measured in hours of social media use per day over 7 days and collected using iPhone screentime function. Sleep quality was determined using the PROMIS T-score. Statistical analysis utilized Pearson's correlation (little: $r < .25$, weak: $r = .25-.50$, moderate: $r = .50-.75$, strong: $r > .75$), t-test ($p < .05$), and effect size (small: Cohen's $d = .20$, medium: Cohen's $d = .50$, large: Cohen's $d > .80$). **RESULTS:** 87 athletes (age: 19.5 ± 1.2 years, 40 males, 47 females) completed the survey. Mean social media use was 4.6 ± 3.4 hours/day. Female athletes spent more time on social media compared to male athletes (5.0 ± 3.2 and 4.1 ± 3.5 hours/day respectively, $p = .018$, Cohen's $d = .27$). No correlation was found between increased social media time and reduced sleep quality ($r = .20$, $P = .068$). Similarly, analysis by sex revealed no correlation in sleep quality (females $r = .22$, $p = .131$, males $r = .18$, $P = .276$). College athletes who spent more time on social media than the mean of 4.6 hrs/day demonstrated worse sleep quality (51.0 ± 8.1 vs. 47.8 ± 7.6 , $p = .130$, Cohen's $d = .41$). When stratified by sex this finding held true for female athletes but not for male athletes (53.2 ± 8.5 vs. 49.1 ± 8.3 , $P = .186$, Cohen's $d = .49$, and 46.3 ± 6.6 vs. 47.6 ± 6.5 , $P = .505$, Cohen's $d = .20$, respectively). **CONCLUSION:** Female college athletes use social media more than male college athletes. Social media use appears to have a negative impact on sleep quality among female college athletes, although more research is needed to explore this. These findings may have implications for developing social media use guidelines for college athletes to improve their sleep quality.

2391 Board #310 May. 28 3:00 PM - 4:30 PM

Psychotropic Medication Use And Concussion History Among Adolescent Athletes

Mary Daley¹, Jessie Oldham¹, Corey Lanois¹, David R. Howell², Rebekah Mannix¹, Diane Sartanowicz¹, William P. Meehan¹. ¹Boston Children's Hospital, Boston, MA. ²Children's Hospital Colorado, Aurora, CO.

(No relevant relationships reported)

An estimated 5-8% of children and adolescents in the United States take prescription psychotropic medications, including antidepressants, stimulants, anxiolytics, antipsychotics, and mood stabilizers. Psychotropics are occasionally used for patients with concussion to treat both cognitive and psychological symptoms, but little is known about the association between psychotropic medication use and concussion history. **PURPOSE:** To examine the relationship between psychotropic medication use with concussion history and concussion symptom burden among adolescent athletes tested at baseline.

METHODS: Data was collected prospectively by the Massachusetts Concussion Management Coalition that contains demographics, medications, and concussion symptom scores from junior high and high school athletes in Massachusetts. Independent samples t-tests were used to investigate differences in concussion history and in symptom scores between those who were and were not on psychotropic medications at the time of baseline testing.

RESULTS: Data was collected from a total of 18,833 adolescent athletes (mean age 14.8 ± 1.7 yrs; 39.6% female). Individuals who were on psychotropics had significantly greater average number of prior lifetime concussions (0.63 ± 0.99 vs 0.34 ± 0.72 concussions; $p < 0.001$, Cohen's $d = 0.34$), and significantly higher symptom scores at baseline (8.67 ± 11.63 vs 4.81 ± 8.25 ; $p < 0.001$, Cohen's $d = 0.38$). Those with a history of depression or anxiety had a significant but smaller increase in number

of prior concussions compared with healthy controls (0.55 ± 0.91 vs 0.34 ± 0.72 concussions; $p < 0.001$, Cohen's $d = 0.26$), and a greater difference in symptom scores (12.4 ± 14.05 vs 4.54 ± 7.8 ; $p < 0.001$, Cohen's $d = 0.69$).

CONCLUSIONS: Adolescent athletes taking psychotropic medications reported a significantly greater number of prior lifetime concussions and higher concussion symptom scores at baseline. Similar trends were seen in those with a history of depression or anxiety, suggesting that these diagnoses alone may be correlated with concussion history and symptom burden regardless of medication use. Future research is warranted to further examine how psychotropic medication use alone may influence these variables, as well as how psychotropics may affect post-concussion symptoms and recovery.

2392 Board #311 May. 28 3:00 PM - 4:30 PM

Accuracy Of The Limb-lead Electrocardiogram In Identifying Conditions Associated With Sudden Cardiac Death

Hung M. Le, Corey J. Lanois, Cynthia J. Stein, Patricia E. Miller, Deanna L. Kerkhof, Gianmichel D. Corrado. *Boston Children's Hospital, Boston, MA.*

Email: hung.le@childrens.harvard.edu

(No relevant relationships reported)

The best screening strategy to prevent sudden cardiac death (SCD) in athletes remains unknown. Using the electrocardiogram (ECG) as a part of a pre-participation examination remains controversial due to the cost and rate of false positives. Screening athletes can be both time intensive and costly. Our previous study demonstrated that using a limb-lead ECG is faster than using a 12-lead ECG. However, the utility and accuracy of limb-leads alone in identifying cardiac abnormalities associated with SCD have never been studied. **PURPOSE:** To assess agreement and diagnostic accuracy in the interpretation of limb lead v. 12-lead ECG in identifying cardiac abnormalities associated with SCD.

METHODS: This study compared the interpretation accuracy of 4 physicians evaluating publicly available ECGs of the most common cardiac conditions associated with SCD in athletes. 4 Medical Sports Medicine fellows participated in the study and each interpreted a total of 100 ECGs: 50 normal ECGs (25 limb lead and 25 12-lead) and 50 abnormal ECGs (25 limb lead and 25 12-lead). The agreement between limb lead and 12-lead ECGs was assessed by Cohen's kappa coefficient and the accuracy of identifying an abnormal ECG was compared across limb lead and 12-lead ECGs using a chi-squared test. Inter-rater and intra-rater reliability were assessed by estimating the Fleiss's kappa coefficient. **RESULTS:** Preliminary data of 150 interpreted ECGs showed an accuracy of 77.8% and 82.1% in identifying abnormal from normal ECGs using 12-lead v. limb-lead, respectively ($p = 0.513$). Based on the readings of the physicians in this study, the sensitivity of limb-lead was 97.2% and 12-lead was 89.5%. The specificity of limb-lead was 69.1% and 12-lead was 64.7%. **CONCLUSIONS:** There was no significant difference in the accuracy of physicians' interpretations of limb lead ECGs compare to standard 12-lead ECGs in identifying cardiac conditions associated with SCD.

2393 Board #312 May. 28 3:00 PM - 4:30 PM

Is Dynamic Ultrasound Of Femoroacetabular Translation Increased In Female Dancers With Acetabular Dysplasia?

Charles Scott, Gregory Kobelski, Patricia Miller, Pierre D'Hemecourt, FACSM, Andrea Stracciolini, FACSM. *Boston Children's Hospital, Boston, MA.* (Sponsor: Andrea Stracciolini, FACSM)

Email: charles.scott@childrens.harvard.edu

(No relevant relationships reported)

BACKGROUND: Hip pain is common in dancers. A contributing factor to hip pathology in dancers may be the high prevalence of acetabular dysplasia. Dynamic ultrasound (US) of femoroacetabular translation has been shown as a reliable measure of femoroacetabular motion and may serve to assist in the evaluation of hip microinstability. Evidence regarding associations between acetabular dysplasia and femoroacetabular translation is unknown.

PURPOSE: To investigate associations between acetabular dysplasia and dynamic US femoroacetabular translation in female dancers with hip pain.

METHODS: Prospective cross-sectional study design. Dynamic US of femoroacetabular translation was performed in three positions: neutral (N), neutral with contralateral hip flexion (NF), and the apprehension position with contralateral hip flexion (EER flexed). Dysplasia was defined using radiographic measures: $LCEA < 25$ or $ACEA < 20$. Multivariable linear regression analysis was used to assess variation in femoroacetabular translation between dancers and non-dancers with and without dysplasia controlling for covariates. Independent variables included age, Beighton score, hypermobility (Beighton score ≥ 5), BMI, and femoral version angles. P -values < 0.05 were considered significant.

RESULTS: The study included 64 female dancers and 92 non-dancer athletes. Dancers were younger ($p=0.001$), had a higher Beighton score ($p=0.006$), and were more likely to be hypermobile ($p=0.005$) compared to non-dancer athletes. Dynamic US femoroacetabular translation was not different in dancers with and without dysplasia ($N, p=0.55$; NF, $p=0.78$; EER flexed, $p=0.93$). Dancers showed greater dynamic US femoroacetabular translation when compared to non-dancer athletes in both the NF position (5.0 ± 2.57 mm, 4.2 ± 2.50 mm; $p=0.04$) and EER flexed position (6.0 ± 2.53 mm, 5.2 ± 2.41 mm, respectively; $p=0.04$).

CONCLUSION: Acetabular dysplasia was not associated with increased dynamic US femoroacetabular translation in this cohort. Dancers showed increased US femoroacetabular translation compared to non-dancer athletes. This finding is likely related to increased ligamentous laxity and stretched ligaments inherent to dance training. Future research is warranted to collect data in asymptomatic dancers with and without acetabular dysplasia.

2394 Board #313 May. 28 3:00 PM - 4:30 PM
Identification Of Functional Popliteal Artery Entrapment Syndrome In Athletes Who Have Failed Compartment Release

Daniel B. Sisk¹, Richard Lawley², Michael Fredericson, FACSM¹. ¹Stanford University, Redwood City, CA. ²Cornerstone Orthopedics, Denver, CO. (Sponsor: Michael Fredericson, FACSM)

(No relevant relationships reported)

ACSM FPAES abstract

TLevel of evidence: IV **Objective:** To evaluate the work up and outcomes of athletes with exertional leg pain, specifically the co-existence of functional popliteal artery entrapment syndrome (FPAES) and chronic exertional compartment syndrome (CECS), in athletes who were unable to return to sport or have significant symptomatic improvement after lower leg compartment fasciotomy. **Design:** Retrospective case series **Setting:** Outpatient musculoskeletal sports clinic, outpatient vascular surgery clinic **Participants:** 36 patients aged 15-67 (average age 26.9) diagnosed with functional popliteal artery entrapment syndrome using CT-angiogram with provocative maneuvers or MRI-angiogram with provocative maneuvers. In our cohort, a moderate number of athletes (11/36 athletes, 19/59 affected limbs) were referred for evaluation by vascular surgery after already having undergone lower leg fasciotomies for chronic exertional compartment syndrome. **Interventions:** Partial debulking of anterolateral quadrant of the medial head of the gastrocnemius muscle with or without fasciotomy **Main Outcome Measures:** Return to sport/previous activities **Results:** Mean follow up was 52.3 ± 22.2 months. 78% (28/36) of the patients were able to fully return to their previous athletic competitive levels. All patients were able to resume their athletic sport at a recreational level. The patients participated in a myriad of sports and athletic activities: 14 runners, 9 soccer players, 3 unspecified, 2 lacrosse, 2 basketball, 1 triathlete, 1 jumper, 1 diver, 1 water polo, 1 rugby, 1 skier. At 6-month follow-up, there were 13% of affected limbs that had recurrent symptoms, at 12 months, only 5% had recurrent symptoms and at three years, no patients had symptoms present. **Conclusions:** Many of these patients were unable to return to participate in high levels at their respective sport even after initial fasciotomy for CECS, suggesting that FPAES was unidentified, overlooked, or possibly developed after fasciotomy. FPAES can be a co-existing diagnosis that warrants screening during the evaluation of CECS. Provocative CT-A and MRI-A protocols can help guide the diagnosis as well as location of muscle debulking to alleviate the functional entrapment that occurs in these athletes with exercise. It is important to consider and screen for this diagnosis to allow for proper treatment and return to sport.

D-74 Free Communication/Poster - Sports Medicine Fellow Clinical Cases

19 Y/o Male Marine Experiencing Exercise-induced Laryngeal Obstruction (eilo) During Military Training.

Matthew Kampert¹, Claudio Milstein². ¹Cleveland Clinic, Shaker Heights, OH. ²Cleveland Clinic, Cleveland, OH.

(No relevant relationships reported)

HISTORY: 19 year old male with a long history of shortness of breath on exertion. States that since childhood he has had inspiratory wheezing and tightness in chest with exertion, but he was told he would outgrow it. More recently, he has noted that it has worsened with maximal exertion during military training. He states that he is

unable to run all out once around the track without experiencing inspiratory difficulty with gasping. It takes about 10 minutes for him to recover. If he resumes exercise it will recur. Asthma inhalers have not helped. Episodes are associated with pain and dysphagia. **PHYSICAL EXAMINATION:** Laryngeal examination shows that there is reduced abduction of the vocal folds, with a maximum glottic space of about 6 mm. During high ventilatory output tasks there is evidence of paradoxical movement of the vocal folds, most prominently on inspiration, resulting in shortness of breath, and loud stridor on inspiration. **Cardiac:** RRR, without murmur **Lungs:** Clear to Auscultation bilaterally "at rest", Loud inspiratory stridor during "high ventilation". **MSK:** Significant muscle tension dyspnea, an inefficient breathing pattern with an upper torso / clavicular breathing, and hyperfunction of strap muscles.

DIFFERENTIAL DIAGNOSIS:- Hypertrophic Obstructive Cardiomyopathy (HOCM)- Asthma- Exercise-Induced Bronchoconstriction (EIB)- Exercise-Induced Laryngeal Obstruction (EILO)- Exercise-Induced Anaphylaxis (EIA) **TEST AND RESULTS:** Cardiopulmonary Exercise Test (CPET): negative. Spirometry with methacholine challenge: negative. Laryngeal function Study: videoendoscopy with stroboscopy revealed reduced abduction of the vocal folds. During high ventilatory provocative challenge, there was evidence of paradoxical movement of the vocal folds, most prominently on inspiration, resulting in shortness of breath, and loud stridor on inspiration. **FINAL/WORKING DIAGNOSIS: Exercise-Induced Laryngeal Obstruction (EILO)** Patient has developed poor breathing patterns with reduced bilateral vocal fold abduction. **TREATMENT AND OUTCOMES:** Breathing Retraining Therapy (4-6 sessions). Patient report significant improvement in symptoms after 2nd session, and complete resolution of symptoms following the 5th session. Remaining symptom free for 4 months.

2396 Board #315 May. 28 3:00 PM - 4:30 PM
The Two-Year Long Pubalgia

George Liras. UT Health, Houston, TX. (Sponsor: Mark Chassay, FACSM)

(No relevant relationships reported)

HISTORY: 20-year-old male collegiate basketball player with prior history of athletic pubalgia s/p repair 2 years ago. The patient was seen in our clinic for evaluation of LLQ abdominal pain that has been present for the past 2 years. During that time, he has had 2 MRIs of the Pelvis w/o contrast showing bone marrow edema and erosive changes in the pubic symphysis and the left superior pubic ramus area and was prescribed physical therapy as well as medication management. The patient also received an ultrasound guided corticosteroid injection in the area for left lower quadrant pain 8 months prior to his visit in our clinic. During the visit the patient reported a fever with a Tmax of 102F the night before, as well as fatigue, cold sweats, chills and groin pain. Of note two days prior, the patient was seen in the ER for a right sided abdominal laceration from a fall of a broken mug. A CT scan of the abdomen and pelvis showed signs of worsening of the previously seen erosive periostitis. He was also found to have an elevated WBC count with left shift.

PHYSICAL EXAM: BP: 125/ 73, T: 98.7 F, HR: 100bpm Constitutional: NAD, AOx 3 Eyes: eyelids normal, conjunctiva and sclera normal, PERRLA, EOMI. Pulmonary: the respiratory rate was normal, the lungs were clear to auscultation bilaterally. Cardiovascular: the heart and rate and rhythm were normal, normal S1, normal S2, no murmurs, rubs or gallops were present. Abdomen: abdominal laceration sutures clean, dry and intact.

DIFFERENTIAL DIAGNOSIS: 1.Osteomyelitis 2.Bone tumor 3.Abdominal Hernia **STUDIES/ LABS:-** ESR: 101 [H]-CRP: 174 [H]-ALP: 139 [H]-ALT: 81 [H]-AST: 74 [H]-WBC: 10.5 [WNL]-Hgb: 12.5 [L]-Hct: 36.1 [L]-Blood smear: Neutrophilia, Normochromic normocytic anemia-ANCA screen: Negative MRI of Pelvis w/o contrast: - Post-surgical changes from repair of left-sided sports hernia - Complex irregular cyst at the repair site - Development of new erosion along the inferior aspect of the pubic symphysis with moderate marrow edema within the pubic bodies and edema of the surrounding soft tissues.

FINAL DIAGNOSIS: Osteomyelitis of pubic bone **TREATMENT AND OUTCOMES:-** Trans-abdominal drainage of pelvic abscess -IV antibiotics (Cefazolin) and transitioned to 6 weeks of PO Keflex under the supervision of Infectious Disease specialist-Patient has recovered well-Will follow up with surgery at the 3 months post-op mark for repeat MRI.

2397 Board #316 May. 28 3:00 PM - 4:30 PM
Abdominal Pain In A Collegiate Quarterback

Allen R. Harris. Crozer Keystone Healthplex Sports Medicine Institute, Springfield, PA. (Sponsor: Thomas Kaminski, FACSM)

Email: allen.harris@crozer.org
 (No relevant relationships reported)

ACSM case Core Injury - Football Allen R. Harris, DO, Crozer Keystone Healthplex Sports Medicine Institute, Suburban Philadelphia, PA (Sponsor: Thomas Kaminski, University of Delaware, ATC, PhD, FACSM) **HISTORY:** A 21-year-old collegiate quarterback sustained a right flank/hip injury during the first quarter of a football game. He scrambled and was tripped from behind falling forward onto the heel of an offensive lineman. He experienced instant pain over his right flank and hip.

He required assistance off the field and complained of pain with breathing. He was immediately escorted to the sports medicine office on-site for examination. **PHYSICAL EXAMINATION:** On examination there was bruising over the lower right abdomen and anterior hip along with tenderness to palpation over the right lower quadrant. No rebound tenderness or guarding. There was marked tenderness over the right ASIS and iliac crest. There was tenderness over the rectus abdominus and right hip flexor. No tenderness over the right upper quadrant. He had decreased strength and range of motion with hip flexion. He did not have dysuria or hematuria. Under ultrasound guidance, the superior aspect of the right iliac crest was injected with 6cc of lidocaine/Sensorcaine in a ratio of 1:2. The patient experienced a 50% reduction in pain and did not return to the game. **DIFFERENTIAL DIAGNOSIS:** 1. Iliac crest contusion (hip pointer) 2. Core muscle injury/avulsion 3. Abdominal contusion **TESTS AND RESULTS:** ultrasound: No free fluid, hematoma or evidence of avulsion or bony disruption. X-ray right hip: No acute fracture. MRI pelvis without contrast: 1. Full-thickness detached tears of the right transversus abdominis and internal oblique muscles at their attachment to the right iliac crest. 2. Grade 1-2 strain of the overlying external oblique muscle. Grade 1 strain of the lateral portion of the right iliacus muscle. **FINAL/WORKING DIAGNOSIS:** Core muscle injury/avulsion **TREATMENT AND OUTCOMES:** 1. Aspiration of hematoma, rest and NSAIDs. 2. Surgical repair of the obliques and rectus abdominis muscles 10 days after initial injury 3. 6-week progressive physical therapy/rehabilitation plan 4. Progressed back to full activity without setback 8 weeks following injury.

2398 Board #317 May. 28 3:00 PM - 4:30 PM
An Unusual Case Of Back Pain
 James McKee. *University of Massachusetts, Worcester, MA.*
(No relevant relationships reported)

HISTORY: A 13-year-old male with a past medical history of Hermansky-Pudlak syndrome was playing soccer and was struck from behind. He presented to the ED complaining of left lateral rib pain with waxing and waning intensity for seven days. The pain was described as a deep ache combined with sharp stabbing pain with deep inspiration without radiation, exacerbated by bending, twisting, and coughing. OTC NSAIDs provided mild relief. He simultaneously also complained of low back pain of unknown lengthy duration. The back pain was a stiffness in the morning that routinely takes until noon to dissipate. ROS otherwise negative. **PHYSICAL EXAMINATION:** Neck: No midline cervical spine tenderness, step-offs, or deformity. Full ROM. Pulmonary/Chest: Effort normal, breath sounds normal. No stridor, wheezes, or rales. Lungs clear bilaterally. Patient reports stabbing pain inferior to left scapula with deep inspiration and lateral bending. No respiratory distress. Musculoskeletal: Normal ROM. No midline spinal tenderness. No tenderness over left posterior ribs. No palpable deformity. Sharp pain just inferior to scapula with inspiration, worse with movement. Straight leg raise negative bilaterally. Steady gait **DIFFERENTIAL DIAGNOSIS:** 1) Rib Contusion 2) Ankylosing Spondylitis 3) Neurogenic **TEST AND RESULTS:** XR Ribs Left: Normal CXR: Normal XR LS: Normal Vitamin D: 27 CRP: 0.4 ESR: 5 RF: <10 HLA-B27: Negative MRI Thoracic and Lumbar Spine: 1) Bone marrow edema in L5 spinous process with small amount of posterior midline subligamentous fluid collection that is likely inflammatory. 2) Congenital narrowing of the bony spinal canal. 3) Syrinx at T5 through T9, up to 2mm at T7. **FINAL/WORKING DIAGNOSIS:** Syringomyelia, spinal stenosis **TREATMENT AND OUTCOMES:** The patient underwent a period of activity modification and PT and clinically improved. Laboratory workup was negative. Lidocaine patches were ineffective. His lower back pain remains unchanged although he states he has received benefits from foam rolling. He decided against playing lacrosse for the spring season. No neurological deficits have manifested. No pulmonary issues have manifested. We continue to recommend that he participated in activities as tolerated with no restrictions.

2399 Board #318 May. 28 3:00 PM - 4:30 PM
Acute Hip Pain In A Female Adolescent Runner
 Catherine Lott. *Detroit Medical Center, Detroit, MI.*
 Email: clott16@gmail.com
(No relevant relationships reported)

HISTORY: 13-year-old female presents for evaluation of left hip pain. Initial injury occurred one day prior to presentation during cross-country practice. She states she was approximately three quarters of a mile into a run on the track when she felt/heard a pop and immediately endorsed pain along the anterior left hip. She described it as sharp in quality with immediate discomfort with ambulation. She was not able to complete the remainder of practice and given the severity and intensity of pain she was taken to the emergency department for further evaluation. While there, plain films were obtained and read as negative for acute fracture. She was given Motrin, placed on crutches and instructed on close follow-up. Since this time, she points to her ASIS and iliac crest as the source of pain with exacerbations during resisted/active hip flexion, internal rotation and weightbearing type maneuvers. She denies any lower extremity radicular symptoms, paresthesias, temperature variations or nocturnal awakenings. Denies any fevers, chills, sweats or loss of bowel/bladder function. She does report some mild hip discomfort over the preceding couple of weeks however

this was transient and self-limiting. She currently runs cross-country and participates in a travel softball team 3 days a week. **PHYSICAL EXAMINATION:** Examination of the left hip revealed no lesion/abrasion or overt deformity; normal alignment, no erythema, swelling or ecchymosis. On palpation she had point tenderness over ASIS and Iliac crest, more so at the ASIS, no crepitus or tenderness at greater trochanter or anterior groin; slight pain over the hip flexor. Patient had full ROM of the left hip but noted pain with both internal rotation and flexion. Patient had mildly decreased strength with resisted hip flexion (4/5), but strength was otherwise normal in the left lower extremity. For provocative testing she had a negative Log Roll, negative FABER; neg FADIR; negative SLR; negative Slump test; positive Trendelenburg; neg Adductor squeeze test. She had normal neurovascular exam of the left lower extremity. The contralateral leg was normal to inspection, palpation, ROM and strength and stability testing. **DIFFERENTIAL DIAGNOSIS:** 1. Sartorius Strain/Rupture 2. Iliac Crest Apophysitis 3. Iliac Crest Apophyseal Avulsion Fracture 4. Psoas Strain 5. Stress Fracture/Reaction

TEST AND RESULTS: Imaging: L hip/pelvis x-rays showed avulsion of the superior aspect of the lateral left innominate bone with the cortical fragment laterally offset. **FINAL/WORKING DIAGNOSIS:** L Iliac Crest Apophyseal Avulsion Fracture **TREATMENT AND OUTCOMES:**

After consultation with surgical colleagues it was decided to proceed with conservative management including ice/heat/NSAID therapy and non-weightbearing with crutch assistance. Patient followed up 2 weeks after the initial clinic visit with improving symptoms. She no longer required crutch assistance for ambulation. Patient was symptom free at 4-week follow up with further radiographic evidence of healing. At this time she was placed in a formal physical therapy program. Completed gradual return to play and was fully participating in running and softball at 8 weeks post injury.

2400 Board #319 May. 28 3:00 PM - 4:30 PM
Let's Talk About Stress
 Lauren Victoria Greene, Sadiq Haque, Brandon Kakos. *Detroit Medical Center, Detroit, MI.*
(No relevant relationships reported)

HISTORY: A 32 year old Female nurse presented to the sports medicine clinic with complaint of left hip pain after she was lifting a patient and twisted her left hip internally. She felt sudden sharp pain over the lateral and anterior hip that radiated into the groin. Pain was made worse with movement and improved with rest and she rated the pain as 7 out of 10 after the injury. Her symptoms continued with little improvement over a few weeks resulting in an antalgic gait favoring the left side. She rates her pain as 6 out of 10 on VAS at presentation. She tried ibuprofen with little relief, has had no imaging or treatment. She runs 3 miles 3 to 5 times per week prior to the injury. She had a history of irregular menses for many years. **PHYSICAL EXAMINATION:** Examination in the clinic revealed a slim female with no swelling or bruising over the left hip. She had tenderness to palpation over the anterior groin and greater trochanter on the left side. She had limited internal rotation of the hip and preserved external rotation. Her strength was preserved and she was neurovascularly intact. She had positive log roll, FADIR and negative FABER. She had an antalgic gait favoring the left side. **DIFFERENTIAL DIAGNOSIS:** 1. Labral Tear 2. Femoroacetabular impingement (FAI) 3. Stress fracture of the femoral neck 4. Hip flexor strain 5. Female athlete triad **TEST AND RESULTS:** Left hip x-rays: 1. Preserved joint space with mild pincer deformity suggesting FAI. No fractures or dislocations noted. MRI Arthrogram of Left Hip: 1. Significant marrow edema and contusion involving a large portion of the femoral neck with a non-displaced stress fracture involving the medial left femoral neck. 2. No labral tear noted. Left Hip Xray 1 week post operatively 1. Three compression screws in the femoral head and neck with adequate alignment and no signs of migration or loosening of the screws. **FINAL/WORKING DIAGNOSIS:** Left femoral neck non-displaced stress fracture with

workup for female athlete triad
TREATMENT AND OUTCOMES: 1. Patient made non weight bearing with crutches. 2. Patient was given options of surgical or conservative management of her compression-sided fracture and chose to pursue surgical route given the fracture extended approx. 50% across the femoral neck and her level of activity prior to the fracture. 3. Closed reduction with percutaneous pinning of the left hip. 4. Using a walker for immobilization she was made 25% weight bearing. 5. 1 week post operatively her pain was improving and she was compliant with weight bearing status. 6. 2 weeks post operatively she continues to improve, she is advanced to 50% weight bearing status using walker and starting physical therapy. She remains off of work as a nurse. 7. Plan to return to work three to four months post operatively.

2401 Board #320 May. 28 3:00 PM - 4:30 PM

Kindness For Weakness

Nicole Nash¹, James Daniels¹, Erica Miller - Spears¹, Rob Carmichael². ¹*Southern Illinois University-Quincy, IL, Quincy, IL.* ²*Culver Stockton College, Canton, MO.*

(No relevant relationships reported)

HISTORY: 21 year old African American male junior running back on the football team presenting with right shoulder and neck pain after tackling an opponent during a game. He had associated numbness and tingling extending down to the right hand. He is right hand dominant. He was seen on the field by the athletic trainers and a burner stinger was initially suspected. He was then re-evaluated on the sideline, and kept out of play due to persistence of symptoms. He denied any symptoms on the left side or in the lower extremities. He does report a history of two burner/stingers in high school. He is otherwise previously healthy with no regular medications. He later came to the training room for further evaluation.

PHYSICAL EXAMINATION: Patient had good range of motion in the neck. Spurling test was negative. Hoffman test was positive. He had global muscle weakness in the right upper extremity. Right shoulder had no swelling or bruising. He had some tenderness over the right bicep tendon. Shoulder range of motion was intact. Sulcus sign and rotator cuff testing were both negative.

DIFFERENTIAL DIAGNOSIS: Burner/Stinger - Brachial Plexus Injury, Cervical Disc Herniation, Spinal Cord Syrinx, Spear Tackler's Spine, Cervical Stenosis
TEST AND RESULTS: X-ray of the cervical spine showed no evidence of acute fracture or subluxation. MRI of the cervical spine without contrast showed a small disc protrusion at C5-C6 and a small area of focal dilation of the central canal at C6-C7 concerning for a syrinx.

FINAL/WORKING DIAGNOSIS: Spinal cord syrinx

TREATMENT AND OUTCOMES: The findings of disc herniation were presumed old, with an acute development of spinal cord syrinx. Patient was referred to an orthopedic spine surgeon who recommended no surgery for the disc and referral to neurology. Neurology started him on baclofen 5 mg twice a day and gabapentin 300 mg twice a day. He has not been cleared to return to play to avoid any further neck trauma. We will continue to monitor his symptoms. He will let us know if he develops any worsening of symptoms. He has a follow up appointment with neurology in 2 months.

2402 Board #321 May. 28 3:00 PM - 4:30 PM

Foot injury- Track & Field

Odrick R. Rosas-Virella¹, Manuel H. Garcia-Cartagena², William F. Micheo-Martinez, FACSM¹. ¹*University of Puerto Rico-School of Medicine, San Juan, PR.* ²*Ponce Health Sciences University, Ponce, PR.*

(No relevant relationships reported)

HISTORY: A 15 y/o female with no medical history, who participates in long jump, triple jump and 200-meter sprints arrived at our clinic (December 2019) with right foot pain partially treated with a pneumatic boot on October 2019. Patient states pain in her right foot, mainly in the first metatarsophalangeal (MTP) joint. Denies burning, irritation, acute trauma, past hospitalizations, surgery or toxic habit, but stated oligomenorrhea for months. Upon further questioning, patient reports having a previous sesamoid fracture of the left foot on May 2017.

PHYSICAL EXAMINATION:

Inspection: Mild edema in the first digit of the right foot
 Palpation: Point tenderness in plantar aspect of the distal part of the first MTP joint bilateral

Range of Motion: Full passive and active in lower extremities

Strength: MMT 5/5 in lower extremities

Single leg hop test positive for pain

DIFFERENTIAL DIAGNOSIS: 1- First MTP joint sprain

2- Stress fracture of sesamoids

3- Sesamoiditis

4- Flexor hallucis brevis tendinopathy

5- Osteonecrosis of hallux sesamoids

TEST AND RESULTS: Lab results: CBC, CMP, uric acid level, U/A, TSH level, A1C, OGTT, RA factor; anti-CCP; C3 and C4 levels; IgA, IgG, and IgM levels;

FT3 and FT4 levels; and Prolactin are all within normal reference ranges. Total testosterone: 119 ng/dL (normal= 5-75 ng/dL), T3 uptake: 35.77% (normal= 20.00%-34.00%), LDH level: 121U/L (normal= 125-243 U/L), and CRP: 1.6 mg/dL (normal= 0.0-1.2 mg/dL).

MRI: Fractured medial hallux sesamoid with bone marrow edema and a small first MTP joint effusion in the left foot, and a small, fragmented and sclerotic medial hallux sesamoid with lateral sesamoiditis (stress fracture) in the right foot.

Left Foot X-Ray: anteroposterior, oblique, and lateral views: Left foot sesamoid fracture had healed.

Pelvic sonogram: Prominent right ovary (3.6x2.7x3.5cm), and normal left-sided ovary with an unilocular cyst measuring 2.2x1.5x2.3cm.

FINAL/WORKING DIAGNOSIS:

Right hallux sesamoid subacute stress fractures.

Left medial hallux sesamoid healed fracture

Suspected female athlete triad.

TREATMENT AND OUTCOMES

1. Physical therapy, home exercises and relative rest from running and jumping.

2. Calcium and Vitamin D supplementation

3. F/U DEXA scan to assess female athlete triad

4. Gradual return to Sports activity

2403 Board #322 May. 28 3:00 PM - 4:30 PM

Progressive Rash In A High School Basketball Athlete

Bram Newman, Adriana Isacke. *Maine Medical Center, Portland, ME.* (Sponsor: Heather Gillespie, FACSM)

(No relevant relationships reported)

History: A 16 year old female high school basketball player presented to the athletic training room with a rash on the bilateral lower extremities. It was first noticed 1 week prior to presentation and had progressed from the feet and ankles proximally to the upper thighs. She stated that she initially had right ankle pain but at presentation felt her left knee was particularly swollen and painful. She denied any significant itching related to the rash but felt her legs were swollen and heavy. She denied any specific joint trauma and had been participating in her usual physical activities. She endorsed that she was currently recovering from an upper respiratory viral illness that occurred prior to the appearance of the rash. She had tried taking oral diphenhydramine for the rash which did not help.

Physical Examination: She was in no acute distress. Nasal congestion and cough were noted. The legs were diffusely swollen from the ankles to the proximal third of the thighs bilaterally with scattered, non-blanching and non-tender purpuric lesions. There was non-specific tenderness to palpation about the left knee without warmth. It was difficult to assess for a knee effusion as there was significant soft tissue swelling. Knee flexion range of motion was 0 to 150 degrees, pain-free and flexion and extension strength was 5/5. Ligamentous structures of the knees were intact. Sensation to light touch of the bilateral lower extremities was intact. She reported pain in the left knee with gait but was not observed as having a limp. Balance was intact.

Differential Diagnosis: 1)Septic arthritis2)Transient synovitis3)Lyme disease4) IgA Vasculitis (formerly known as Henoch-Schnlein Purpura)5)Coagulopathy6) Dermatologic hypersensitivity

Tests and Results: The patient was sent to the emergency department for further evaluation. Blood pressure was 116/69, pulse was 90, respiration rate was 19 breaths per minute with 100% oxygen saturation, and temperature was 97.5°F. A complete blood count showed normal platelets and no leukocytosis, while a basic metabolic panel showed normal renal function. A urinalysis showed trace blood and left lower extremity vascular ultrasound was negative for DVT. Musculoskeletal ultrasound did not show any intra-articular effusion in the left knee.

Final/Working Diagnosis: IgA Vasculitis (formerly known as Henoch-Schnlein Purpura) with polyarticular involvement.

Treatment and Outcomes: Our patient was managed conservatively with symptom management as needed. Although there was concern for septic arthropathy, she remained afebrile with no clinical signs of sepsis. The rash and arthralgias resolved within 4 weeks.

A RARE CASE OF WRIST PAIN IN AN ADOLESCENT TENNIS PLAYER

Marc Phillip Gruner, Jacob Sellon, Edward Laskowski. *Mayo Clinic, Rochester, MN.*

Email: grunerm@gmail.com

Reported Relationships: M.P. Gruner: OOwnership/interest/stock; own stocks.

CLINICAL CASE -16 year old tennis athlete with dorsal wrist pain

HISTORY: A 16 year old female left-handed high school tennis athlete presented with a several month history of left dorsal wrist pain. She had an episode of whole arm pain, which resolved spontaneously, prior to the wrist pain, but she continued to

THURSDAY, MAY 28, 2020

experience dorsal wrist pain. She described diffuse pain about the dorsal aspect of the wrist radiating into the left hand. She denied mechanical symptoms, swelling, discoloration, or paresthesias. She also denied neck pain.

PHYSICAL EXAMINATION: Skin was grossly negative for erythema, breakdown, or concerning lesions in the left wrist/hand region. Neurologic exam: 5/5 strength in all forearm and hand muscles without atrophy, sensation was intact to light touch C5-T1, and tinel test was negative over the superficial radial nerve. Musculoskeletal wrist exam: no swelling or deformity. No focal tenderness or mass. Full active and passive range of motion of the wrist. There was no pain or laxity with distal radial ulnar joint shucking. There was no pain or laxity with distal radial ulnar joint shucking. There was no pain or laxity with distal radial ulnar joint shucking. There was no pain or laxity with distal radial ulnar joint shucking.

DIFFERENTIAL DIAGNOSIS: 1. Ganglion cyst of the wrist joint. 2. Sprain of the dorsal scaphoid-lunate ligament. 3. Symptomatic extensor digitorum brevis manus. 4. Dorsal Impaction syndrome. 5. Extensor tendinopathy.

TEST AND RESULTS: Ultrasound examination revealed an extensor digitorum brevis manus accessory muscle traversing from the deep side of the 4th dorsal extensor compartment, extending across the dorsal hand, and terminating into a tendon slip that merged with the dorsal extensor hood of the 3rd digit. The muscle was notably larger on the left side than the right. She had no evidence of tenosynovitis or other abnormalities in the dorsal wrist.

MRI of the wrist revealed a tiny ganglion cyst along the volar margin of the radioscaphoid articulation and a normal variant extensor digitorum manus brevis muscle.

FINAL/WORKING DIAGNOSIS: Symptomatic extensor digitorum brevis manus. **TREATMENT AND OUTCOMES:** 1. Immobilization. 2. Diclofenac Gel. 3. Ultrasound guided Botox injection of the extensor digitorum manus brevis muscle.

We discussed different management options and she elected to proceed with an ultrasound guided botox injection since she had minimal relief from immobilization.

Adverse To Converse

Jeevan Abraham¹, Raman Singh². ¹AMITA Resurrection Medical Center, Chicago, IL. ²Advocate Health, Aurora, IL. (Sponsor: Poonam Thaker, FACSM)

(No relevant relationships reported)

Toe Pain--- Cross-Country

HISTORY: A 12 year-old female cross country runner presented to the pediatric sports medicine clinic with 3 months of right second toe pain. Initially, the pain started after stubbing her toe. She developed a constant dull ache that was present at rest and worsened with prolonged walking and during cross country. She noted that her symptoms gradually worsened with time, and she was having no improvement with rest, icing and anti-inflammatories.

PHYSICAL EXAMINATION: Overlying skin with no rashes or lesions. Tenderness along the plantar surface of her right second metatarsophalangeal (MTP) joint. ROM was limited in both passive and active flexion and extension of the affected joint. Sensation was intact, and strength with flexion and extension of the toe was normal, however there was significant pain with testing. MT squeeze test was negative. Varus and valgus stress to MTP joint elicited no laxity, and "drawer test" of MTP joint showed mild instability.

DIFFERENTIAL DIAGNOSIS:

1. Sprain of plantar plate
2. Metatarsal fracture/stress fracture
3. Osteochondrosis of the metatarsal head
4. Metatarsalgia
5. Lisfranc injury
6. Intermetatarsal neuroma

TEST RESULTS:

X-ray R foot:

--- Flattening of the second metatarsal head.

MRI R foot without contrast:

--- Flattening/collapse of the 2nd metatarsal head/distal epiphysis with prominent marrow edema of the 2nd metatarsal head and neck. Mild MTP joint space narrowing.

FINAL/WORKING DIAGNOSIS:

Osteochondrosis of the metatarsal head (Freiberg Disease) - Stage 4

TREATMENT AND OUTCOMES:

1. Placed in short leg walking boot with protected weight-bearing, ice 1-2 times daily, Foot/Ankle Surgery consultation with discussion of conservative care vs surgical (chondral drilling and/or chondroplasty). Patient opted for conservative care.
2. At 4-week follow-up, patient's pain significantly reduced. Continued walking boot additional 4 weeks with transition into stiff-soled shoe.
3. At 8-weeks post treatment, follow-up MRI showed no progression of disease. Clinically with almost complete resolution of pain.
4. By 10 weeks, transitioned into a custom foot orthotic with added support to float 2nd MTP joint. Restrictions included low impact sports only with plan for repeat MRI at 6 months.

Bilateral Shoulder Pain - Baseball

Frances Adkins Comer, Anastasia Fischer, FACSM. *Nationwide Children's Hospital, Dublin, OH.* (Sponsor: Anastasia Fischer, FACSM)

Email: frances.comer@nationwidechildrens.org

(No relevant relationships reported)

HISTORY: A 14-year-old right handed baseball player presents with two and a half years of insidious-onset bilateral shoulder pain. The pain is generalized in both shoulders, but worse anteriorly and in the right shoulder. He has continued to play year-round at an elite level, but he had to stop pitching due to pain. His shoulders "catch" and pain is exacerbated with rapid movements. **PHYSICAL EXAM:**

Examination in clinic demonstrated tenderness of the anterior and posterior humeral head on the right and anterior humeral head on the left. Range of motion is limited in extension, internal rotation, and external rotation, and is full in flexion and abduction. Strength is full in all ranges of motion with pain in abduction, internal and external rotation. Hawkins, O'Brien's, and Crank tests are positive for pain. He is distally neurovascularly intact. **DIFFERENTIAL DIAGNOSIS:** 1. Labral tear. 2. Proximal Humeral Epiphysiolysis. 3. Synovial Osteochondromatosis. 4. Dysplasia Epiphysialis Hemimelica. **TEST AND RESULTS:** Bilateral shoulder radiograph: Abnormal rounded ossific densities anterior to the right humeral head and metaphysis. Similar pattern of ossification anterior to the left humeral head, which is less well-defined than that seen in the right shoulder. Bilateral shoulder MR without contrast: Bilateral symmetric irregularly-shaped osteochondral fragments within the anterior glenohumeral joint spaces with evidence of erosions of the humeral head. Bilateral shoulder CT without contrast: Bony irregularity along the medial, proximal aspect of both humeri with clustered ossicles adjacent to the bony irregularity. No evidence of free intra-articular bodies. **FINAL/WORKING DIAGNOSIS:** Bilateral Synovial Osteochondromatosis of the Shoulders. **TREATMENT AND OUTCOMES:** 1. Referred for a surgical consult, where non-operative treatment was recommended. 2. Started in physical therapy (PT). 3. Continued full participation in sports despite pain. 4. 10-15% improvement after 3 months of PT. 5. Currently travelling for the winter baseball season and continuing PT at a distant site.

An Unexpected Cause For Hip Pain

Adam Stefaniak. *Resurrection Medical Center, Chicago, IL.*

(Sponsor: Poonam Thaker, FACSM)

Email: awstefaniak@gmail.com

(No relevant relationships reported)

Clinical Case Abstract

Right hip pain-Runner

Adam Stefaniak, DO Resurrection Sports Medicine Fellowship, Chicago, IL. (Sponsor: Poonam Thaker, MD, FACSM)

HISTORY: The patient is a 17 year old male who presented with his mother for right hip pain that started 4 months prior to evaluation. There was no known injury when the pain started. The pain was located anteriorly and in the groin. He described the pain as sharp with radiation down his femur. He also started limping recently because of worsening pain. The pain worsened with running, walking, and standing for long periods of time. He felt like his hip sometimes would get "stuck", but denied any snapping, popping or clicking. Pain improved with ibuprofen. He ran track during spring, but he denied participating in any sports or increase in activity prior to the pain starting. Denied back or knee pain. No previous injuries to that hip. Denied fevers, chills, night sweats, weight loss.

PHYSICAL EXAMINATION: Antalgic gait. Right Hip- No swelling or bruising. No pain over iliac crest, ASIS, AIIS, PSIS, greater trochanter, IT band. Hip flexion 120, external rotation 45, internal rotation 35. 4/5 hip flexion strength. 5/5 hip extension, knee extension, knee flexion, dorsiflexion, plantar flexion. Positive groin pain with FABER testing. Negative FADIR. Negative log roll. Pain with resisted straight leg test. Pain with jump testing. Negative Ober's test.

DIFFERENTIAL DIAGNOSIS: 1. Hip labral tear. 2. Stress fracture. 3. Snapping hip syndrome. 4. FAIS. 5. Muscle strain. 6. Osteitis pubis. 7. Athletic pubalgia

TESTS AND RESULTS:

Right Hip and Pelvis Xray: nMild osseous expansion with sclerotic and lucent areas involving the left pubic bone. Right Hip and Pelvis MRI without contrast: nMultiple aggressive appearing osseous lesions throughout the pelvis, proximal femurs, and lower lumbar spine, compatible with metastatic disease. CT biopsy performed of the right ischial bone lesion. CD20+ Diffuse B-cell Lymphoma

FINAL/WORKING DIAGNOSIS: Diffuse B-cell Lymphoma

TREATMENT AND OUTCOMES: 1. Referral to pediatric hematology/oncology. 2. 10 cycles of intrathecal R-COPADM chemotherapy (ANHL1131 protocol). 3. Activity as tolerated

2408 Board #327 May. 28 3:00 PM - 4:30 PM

Acute Blindness In An Athlete

Sarah Abdellatif, Kevin Lisman, Rehal Bhojani. *UT Health in Houston, Houston, TX.* (Sponsor: Mark Chassay, FACSM)
(No relevant relationships reported)

TITLE: Acute Blindness in an Athlete
PRESENTER: Sarah Abdellatif, DO
HISTORY: A 24 yo weightlifter with a past medical history of mitral valve prolapse and Raynaud’s syndrome experienced sudden right eye blindness about one month ago after training at the gym. She finished her session at the gym that day with no issues. Once patient returned home, she decided to sit down and read for a bit when she suddenly lost vision of her right eye. She had no precipitating symptoms. Patient took an aspirin and her vision returned in about thirty minutes. She states that the image was slightly pixelated when it returned. Patient had never had anything like this happen before and had not happened again after that episode.
PHYSICAL EXAMINATION: Height- 66 inches Weight- 112 pounds Blood Pressure- 132/76 HEENT- Extraocular movements intact. Pupils equal and reactive to light. Neck- JVP normal, carotid pulses are full and equal bilaterally without bruits
Cardiac- Regular rhythm and rate, S1 normal, S2 normal, so S3 or S4, no murmurs, no gallops, no rubs detected
Peripheral Pulses- Femoral, popliteal, dorsalis pedis, and posterior tibial pulses are full and equal bilaterally with no bruits auscultated.
Neuro- Cranial nerves 2-12 intact.
DIFFERENTIAL DIAGNOSIS: 1. Patent Foramen Ovale 2. Central Retinal Artery Occlusion 3. Carotid Stenosis 4. Hemiplegic Migraine 5. Multiple Sclerosis
TEST AND RESULTS: Complete 2D Echocardiogram-- The left ventricular systolic function is normal with an estimated EF 60-64%. Patent foramen ovale is seen with left to right shunting.- Qp:Qs ratio is 0.72.- There are no hemodynamically significant valvular abnormalities or insufficiencies noted on this study.
FINAL/WORKING DIAGNOSIS: Large bidirectional shunting via patent foramen ovale with possible aborted central retinal artery occlusion stroke
TREATMENT AND OUTCOMES: 1. Start aspirin and Plavix daily. 2. TEE and a cardiac CTA to include origin of great vessels and carotid arteries. 3. Check a seven day cardiac monitor. 4. Schedule for PFO closure once results return. Risks and benefits discussed, given patient’s level of activity. 5. Refer to stroke neurologist for multidisciplinary evaluation.

2409 Board #328 May. 28 3:00 PM - 4:30 PM

Mesenchymal Stem Cell Use For ACL Repair: A Case Report

Navid Javan¹, Andrew Blecher². ¹Dignity Health Northridge, Northridge, CA. ²Southern California Orthopedic Institute, Van Nuys, CA.
(No relevant relationships reported)

HISTORY: The subject of this case is a 41-year-old stuntman who was referred for non-surgical consultation for left knee pain and inability to return to work after being hit by a car 2 years prior. He had been treating his knee with rest and a hinged knee brace which had partially improved his pain. He did not report any instability but had not yet “tested” his knee. He had no injuries to this knee prior to that incident. He takes no medications and had no prior surgeries.

PHYSICAL EXAMINATION: He had no effusion, deformity or focal tenderness. He had full AROM and strength was 5/5. He had 1+ laxity on Lachman maneuver and anterior drawer testing. McMurray, varus stress, and valgus stress were all negative.

DIFFERENTIAL DIAGNOSIS: 1) ACL Sprain 2) ACL Rupture

TEST AND RESULTS:

KT1000 testing was performed and showed a 4 mm difference at the 15 lb. level and a 5 mm difference with quadriceps active displacement. MRI of the left knee demonstrated a grade 2 ACL sprain with only a few fibers left intact. MRI also demonstrated an impaction contusion injury of the medial tibial plateau and a small medial meniscal tear. (Figure 1a)

FINAL/WORKING DIAGNOSIS: Grade 2 ACL Sprain of the Left Knee

TREATMENT AND OUTCOMES: He first verified that he had not taken any NSAIDs within the previous 2 weeks and wouldn’t take any for the next 12 weeks. He received a centrifuged PRP intra-articular knee injection. The patient returned 2 days later for a mesenchymal stem cell (MSC) injection. Bone marrow aspirate was collected from the posterior iliac crest bilaterally and then processed, centrifuged and separated using the Regenxx technique which resulted in MSC, platelet lysate (PL), and a superconcentrated platelet solution (SCP). The PL and SCP was injected intra-articularly. The MSC were injected into the course of the ACL remnant under fluoroscopy. The patient was placed in a knee immobilizer and then received an intra-articular injection of SCP and PL 5 days later. He was evaluated twice over the next two weeks, being advanced to an ACL brace and PT. His ACL brace became pm 8 weeks later. At 6 months he had 90% improvement of his pain with discomfort during backwards running and deceleration but had no instability. He was cleared to return to his occupation as a stuntman. At 9 months he had an intact ACL on MRI (Figure 1B) and complete resolution of his pain.

2410 Board #329 May. 28 3:00 PM - 4:30 PM

Case Of A Pathologic Phalanx Fracture

Adam Thompson. *Crozer Keystone Health System, Springfield, PA.* (Sponsor: Thomas Kaminski, FACSM)
(No relevant relationships reported)

Phalanx Fracture

Adam M. Thompson, Crozer Keystone Health System, Springfield, PA. (Sponsor: Thomas Kaminski, ATC, PhD, David Webner, MD, Kevin DuPrey, DO)

HISTORY: A 24 year old right hand dominant male presented to urgent care with a hand injury sustained while moving a refrigerator. He was attempting to lift the refrigerator when he dropped it and it landed on his left hand. It landed on his middle and ring fingers. He developed pain and swelling primarily in the middle finger but with some in the ring finger as well.

PHYSICAL EXAM: Vital signs were within normal limits. Examination of the patient’s left hand demonstrated swelling and ecchymosis over the middle phalanx of the middle and ring fingers along with tenderness to palpation. There was equal range of motion in pronation, supination, wrist extension and wrist flexion bilaterally. There was decreased active flexion and full extension in those fingers as well - MP 0/85, PIP 0/75, DIP 0/35. Skin was warm and dry. Capillary refill was brisk.

DDX: 1. DIP/PIP ligament sprain 2. Phalanx fracture 3. Flexor tendon injury

TESTS AND RESULTS: X-ray demonstrated an angulated middle finger middle phalanx fracture with an underlying circumscribed lucent lesion with cortical thinning and some suggestion of internal matrix with somewhat limited evaluation secondary to fracture favored to represent a unicameral bone cyst or enchondroma.

FINAL/WORKING DIAGNOSIS: Left long finger middle phalanx cyst, consistent with bone cyst/enchondroma with pathologic fracture.

TREATMENT/OUTCOMES: The patient was referred to hand surgery for evaluation due to the fracture extending through the bone cyst. He underwent ORIF for pathologic fracture 7 days post injury. He was placed in a splint post-operatively. At initial follow-up he demonstrated good wound healing and significant improvement in pain. He was placed in a custom splint which he wore for six weeks. At this time he started in hand therapy to work on return to full function.

A Writer’s Block

Cindy Ong. *Kaiser Permanente, Los Angeles, CA.* (Sponsor: Aaron Rubin, FACSM)

Email: cindyong510@gmail.com

(No relevant relationships reported)

HISTORY: A 32-year-old male writer had right shoulder pain for four weeks without inciting injury and possibly slept awkwardly on his couch. The pain radiated with numbness/tingling along his right arm, forearm, and right thumb. His pain feels like “a bad sunburn.” His severe pain led to two prior emergency department visits and was provided a sling, Norco and lidocaine patch with minimal relief. He tried NSAIDs, acupuncture, cupping and physical therapy with mild relief. He finished a prednisone burst with improvement, however, with residual shoulder pain with overhead activities. He had also been recovering from a recent viral syndrome before his pain started.

PHYSICAL EXAMINATION: Neck: no tenderness over C-spine and paracervical muscles, normal ROM, strength decreased in right C5 4+/5, negative Spurling’s. Right Shoulder: mild forward slumping, tenderness over bicipital groove. ROM normal except internal rotation (IR) at L1 (left IR T6), pain at end arc flexion and abduction, Neer’s/Hawkin’s test positive. Scapula rotation asymmetric, mild dyskinesia, right scapula mildly more protracted than left. Sensation decreased on ulnar/radial C6 and C8 distribution. Radial pulse symmetric. **DIFFERENTIAL DIAGNOSIS:** 1. Neuralgia amyotrophy/brachial neuropathy/brachial neuritis (Parsonage-Turner syndrome) 2. Dorsal scapular nerve entrapment 3. Rotator cuff syndrome 4. Quadrilateral space syndrome 5. Cervical spinal stenosis. **TEST AND RESULTS:** Cervical Spine Radiographs:— Normal. MRI Cervical Spine No Contrast:— Degenerative changes, mild-moderate right neural foraminal narrowing at C3-C4 without spinal canal stenosis. Small central disc protrusion without stenosis at C6-C7. MRI Right Shoulder

No Contrast:— Mild supraspinatus and infraspinatus tendinosis, no tear. Edema

within teres minor without atrophy, possible denervation changes versus muscle strain. **FINAL/WORKING DIAGNOSIS:** Neuralgic amyotrophy. **TREATMENT AND OUTCOMES:** The patient had follow ups with sports medicine and orthopedics with gradual improvement with conservative therapy, including NSAIDs, steroids, rest and physical therapy. He tolerated more of his physical therapy exercises with nerve gliding, increasing range of motion and strengthening.

2411a Board #331 May. 28 3:00 PM - 4:30 PM Hand Injury

Marcin Jungiewicz, Kaleigh Suhs. *Advocate-Aurora Lutheran General Hospital, Park Ridge, IL.* (Sponsor: Mark Hutchinson, FACSM)
 Email: moi1791@gmail.com
 (No relevant relationships reported)

HISTORY: A 15 year old H.S. football quarterback sustained a right thumb injury while throwing a pass. His hand hit a defender's chest during follow through, jamming his thumb. He noted swelling and bruising over thenar eminence and his 2nd MCP joint. This resulted in limited ROM of the right thumb especially of abduction and opposition. **PHYSICAL EXAMINATION:** Examination of the right hand showed edema along the 1st MCP joint, thenar eminence with ecchymosis in 1st webspace extending into 2nd MCP joint. Skin was intact. Thumb was well vascularized. No tenderness over 2nd metacarpal or 2nd MCP joint. Thumb opposition and 1st MCP flexion and extension less than 20° were limited by edema and pain, IP ROM was within functional limits. Tenderness over ulnar aspect of 1st MCP joint. Pain and tenderness present during MCP extension with mild laxity with UCL stressing. Laxity at the CMC joint with some dorsal subluxation, reducible. Tenderness proximal to trapezium. Contralateral side thumb revealed also some laxity at the CMC. **DIFFERENTIAL DIAGNOSIS:** 1. Fracture of the right 1st Metacarpal bone 2. Fracture of the right thumb proximal phalanx 3. Fracture of the wrist bones 4. Right 1st MCP joint UCL sprain **TEST AND RESULTS:** X-rays of the right hand 3V: No bony or soft tissue abnormalities. MRI right hand ordered to rule out occult fracture(s), ligament tears: 1. Nondisplaced fracture of the trapezium. Diffuse bone marrow contusion in the 1st metacarpal with small avulsion fragment of the radial metacarpal at RCL attachment 2. Bone contusion of the distal dorsal capitate 3. Moderate grade sprain of UCL and RCL at the thumb MCP joint with partial tearing of proximal RCL at the avulsion fragment. 4. Diffuse low grade muscle strain with superimposed partial musculotendinous tear of flexor pollicis brevis muscle. **TREATMENT AND OUTCOMES:** 1. Wrist and thumb immobilization in Custom thumb spica splint to enable graduated ROM as tolerated and Occupational Therapy 2. Restriction from all contact sports for 6 weeks 3. Consultation with Hand Orthopedist to evaluate for surgical necessity determined patient to be appropriate for conservative treatment. Patient seen in Sports Medicine Clinic 39 days after initial injury. Returned to sports after 6 weeks of immobilization with thumb/wrist taped. Patient denied pain with activity.

2411b Board #332 May. 28 3:00 PM - 4:30 PM Chronic Shoulder Pain Secondary To Trampoline Injury

Johnel Mayberry¹, Terry Nicola, FACSM¹, Kevin Machino².
¹University of Illinois at Chicago, Chicago, IL. ²Rush University, Chicago, IL. (Sponsor: Terry Nicola, FACSM)
 Email: jaymayberry15@gmail.com
 (No relevant relationships reported)

HISTORY: 14 year old female with right shoulder pain and arm paresthesias after trampolining injury 17 months prior to visit. Her right arm was yanked down and she heard a pop. Pain initially improved but recurred during basketball tryouts 6 months later. At presentation she noted right shoulder "spasm" pain rated 2/10 at rest and worsened to 5/10 with repetitive activities. Most bothersome symptoms were aching, tingling sensation on the medial aspect of her right arm radiating into the 3rd-5th digits with hand weakness. **PHYSICAL EXAMINATION:** Right first rib was elevated with tenderness. The right middle scalene was notable for spasm with tenderness. Right scapula winging noted. Positive right lift-off test. Weakness in the right abductor pollicis brevis, 3/5 on motor testing. No sensory or other strength deficits. Radiating symptoms reproduced with right shoulder mobility. Negative Neers, Hawkin's and speed's. Positive Roo's maneuver on the right at 15 seconds. Negative Adson's test bilaterally, Negative Tinel's test at the right elbow and wrist. Negative Spurling's and Lhermitte's. **DIFFERENTIAL DIAGNOSIS:** #1-Neurogenic thoracic outlet syndrome #2-Brachial plexopathy #3-Vascular thoracic outlet syndrome **TEST AND RESULTS:** MRI Right brachial plexus - No mass or focal abnormality along right brachial plexus. Diminutive appearance of right internal jugular vein of uncertain clinical significance. MRI of cervical spine - No evidence of neural compromise. Electrodiagnostic exam - There was a 25% decrease in the right median motor amplitude compared to the left. No side to side difference in ulnar nerve studies. The

scapular stabilizers were not evaluated. Vascular Doppler Evaluation - Dampened plethysmography waveforms in the right arm in the Adson maneuver when compared to the left. **FINAL/WORKING DIAGNOSIS:** Arterial thoracic outlet syndrome **TREATMENT AND OUTCOMES:** Dry-needling of the right anterior and middle scalene muscles were performed. Physical therapy was prescribed with focus on stretching the scalenes and pectoralis muscles. She is no longer having symptoms at rest and her strength is significantly improved. She continues to have right 3rd-5th digit paresthesias with prolonged activities despite focused physical therapy and is undergoing surgical evaluation.

D-75 Clinical Poster/Reception - Clinicians' Reception with Poster Presentations

Thursday, May 28, 2020, 6:00 PM - 7:00 PM
 Room: Hotel-Nob Hill

2412 Board #1 May 28 6:00 PM - 7:00 PM Influence Of Injury Severity And Recovery Environment On Physical Activity And Function Following Lower-limb Amputation

Peter Laddow (Sponsor: James Betts, FACSM)¹, Thomas E. Nightingale², M. Polly McGuigan³. ¹UK Ministry of Defence, Loughborough, United Kingdom. ²University of British Columbia, Vancouver, BC, Canada. ³University of Bath, Bath, United Kingdom.
 (No relevant relationships reported)

Restoration of physical function and physical activity (PA) is considered a vital therapeutic component in the short-term rehabilitation and long-term recovery of individuals with traumatic lower-limb amputation(s) (LLA). Unfortunately, evidence suggests an increased prevalence of physical inactivity and reduced functional status in this population. **PURPOSE:** To determine the impact of free-living environment (rehabilitation vs. home) on PA and function in UK military personnel following traumatic LLA, compared to active non-injured controls (CON). **METHODS:** Sixteen LLA (8 unilateral (UNI), 30±5yrs; 8 bilateral (BI), 29±3yrs), nearing the end of their clinical rehabilitation care pathway, attended one 4-week residential rehabilitation admission and one 6-week recovery block at home. Thirteen physically active, age-matched males (28±5yrs) represented CON. Estimated daily ambulatory PA energy expenditure (PAEE) was estimated from an accelerometer (Actigraph GT3X+), worn on the hip of the shortest residual limb in each environment, using validated population specific prediction algorithms. Six minute walk distance (6MWD) was recorded at baseline and 10 weeks (general population 6MWD norms is >459m). **RESULTS:** Whilst at home, mean PA counts.day⁻¹ reduced by 17% (p=0.018) and 42% (p=0.001) in the UNI and BI group, respectively. UNI group demonstrated a similar capacity for PAEE to CON, both of which were greater (P<0.05) than BI (Table 1). No significant changes in 6MWD were demonstrated within groups (P>0.05), however, significant differences (P<0.05) were demonstrated between all groups at baseline (UNI, 574±66m; BI, 337±85m, CON, 705±32m). **CONCLUSION:** UNI group demonstrate a similar capacity for PA and function to active non-injured CON. To support and manage the long-term health and well-being of more severely injured BI LLA, future research should investigate strategies that promote regular engagement in PAEE, particularly when they return home.

Estimated daily physical activity in all groups. Data presented as mean±SD and Δ mean							
	Unilateral Amputation (n=8)	Bilateral Amputation (n=8)	Control (n=13)				
	Rehabilitation	Home	ΔChange	Rehabilitation	Home	ΔChange	Work
Days (>14 hours)	5 ± 1	5 ± 1	0	6 ± 1	6 ± 1	0	5 ± 1
Wear Time (minutes)	918 ± 41	916 ± 55	-2	918 ± 45	904 ± 42	-14	934 ± 40

2413 Board #2 May 28 6:00 PM - 7:00 PM

Does Immobilization Period Affects The Functional Outcomes After Bankart Repair?Irem Duzgun, Taha I. Yildiz, Gazi Huri, Dilara Kara, Ceyda Sevinc, Egemen Turhan, Serdar Demirci, Leyla Eraslan, Elif Turgut, Ozgur A. Atay. *Institution of Health Sciences, Ankara, Turkey.**(No relevant relationships reported)*

There is no consensus about the absolute immobilization time period and whether the rehabilitation should start in the first or in the third week after Bankart Repair.

PURPOSE: The aim of this study was to compare the clinical outcomes of 1 and 3 weeks of absolute immobilization time after the surgery and evaluate their effects on recurrent instability. **METHOD:** Forty-two patients with arthroscopic Bankart surgery were included to the study. Patients were randomly allocated into two groups. One week of absolute immobilization was performed to the patients in group-1 (n=21, age:24.7±7.1, BMI: 25.3±3 kg/cm²) and 3 weeks of absolute immobilization was performed to the patients in group-2 (n=21, age: 22.1±6.7 years, BMI: 24.8±2.8 kg/cm²). All of the patients come to the clinic once in a week and performed supervised exercise program and the rehabilitation program was progressed. They were also prescribed home exercise program. Shoulder ROM, pain level and shoulder function were assessed, according their groups at the first or third weeks, 4, 8 and 12 weeks of post-operative period. The pain level during resting, activity and at night was assessed with VAS. Shoulder ROM was assessed with standard goniometer and shoulder function was assessed using ASES questionnaire. At the average of 30. weeks after the surgery, it was questioned whether there was a re-dislocation. The demographics of the patients on both groups were analyzed with student t test. Two-way repeated measures ANOVA was used for the statistical analyses. **RESULTS:** There were no significant the "Group*time" interactions for pain at rest and activity and flexion, abduction, external rotation, internal rotation angles (p>0.05). The main effect of time was significant at rest and activity pain and all ROM measurements (p<0.05). There was a significant "Group*Time" interaction for pain at night (p<0.05). Pain at night was higher in the group-1 at post-operative 1 and 4. weeks compared to group-2. There were no statistically significant differences between the two groups in shoulder function at post-operative 12 weeks (p>0.05) and 30 weeks (p>0.05). One patient had re-dislocation in the group-2. **CONCLUSION:** One or three weeks of absolute post-operative immobilization period does not differ in terms of functional outcomes on patients with Bankart repair.

2414 Board #3 May 28 6:00 PM - 7:00 PM

The Effect Of Injuries And Pain On Athletic Identity Across NCAA DivisionsBryanna Veroneau (Sponsor: Stephen Bailey, FACSM)¹, Bailey Tadlock¹, Shefali Christopher¹, Srikant Vallabhajosula¹, Amy Knab², Chris Harnish³, Garrett Bullock⁴. *Elon University, Elon, NC. ²Queens University of Charlotte, Charlotte, NC. ³Mary Baldwin College, Staunton, VA. ⁴University of Oxford, Oxford, United Kingdom.**(No relevant relationships reported)*

There is a high prevalence of pain and injury in collegiate athletes, which can affect playing time and performance. Previous studies have observed that surgery and concussions can affect athletic identity. Currently, there is a paucity of research investigating how current pain and injury affect athletic identity.

Purpose: To determine how current collegiate athlete pain and injury affect athletic identity and how these relationships differ across NCAA divisions. **Methods:** NCAA division 1 (D1), 2 (D2), and 3 (D3) athletes were administered a questionnaire through an encrypted database. The Athletic Identity Questionnaire (AIM) and Oslo Sports Trauma Research Center Overuse Injury Questionnaire (OSTRC) were used within the survey. AIM estimates self-perceived athletic identity while OSTRC measures level of participation, training volume, performance, and pain. Athletes were further classified by OSTRC scores into overuse and substantial overuse injuries. Multivariable and logistic regressions assessed the relationship between Aim, OSTRC scores, and overuse injury. Models were adjusted for age, gender, NCAA division, history of orthopedic surgery, and history of major injury, with unadjusted and adjusted coefficients and Odds Ratios (OR) with 95% confidence intervals (95% CI). **Results:** 252 athletes (age of 19.4 years (1.2); female: 181, male: 70; D1: 101, D2: 74, D3: 77) participated. Mean AIM scores were D1: 37.98 (7.61), D2: 37.03 (37.03), and D3: 38.86 (6.98). The OSTRC median score was 0 (IQR: 0-22). 127 (50%) athletes had an overuse injury while 47 (19%) had a substantial overuse injury. Adjusted total OSTRC score was -0.67 (95% CI: -2.4, 1.1; p=0.474). Adjusted OR for OSTRC overuse injury was 1.00 (95% CI: 0.97, 1.04; p=0.589) and substantial overuse injury was 0.95 (95% CI: 0.91, 0.99; p=0.036). Similar results were observed between gender and division subgroups. **Conclusion:** After adjusting for confounding variables, it was determined that substantial overuse injuries negatively affected athletic identity, regardless of gender or NCAA division. Sports medicine professionals need to consider the

possibility of lost athletic identity when an athlete sustains an injury. Measures should be taken to ensure that athletes continue to have meaningful contribution to sport following pain or injury.

2415 Board #4 May 28 6:00 PM - 7:00 PM

Masters Athlete Screening Study: Four-Year Cardiovascular Disease and Event IncidenceBarb N. Morrison¹, Darren E. R. Warburton², Jack Taunton, FACSM². *¹SportsCardiologyBC, Vancouver, BC, Canada. ²University of British Columbia, Vancouver, BC, Canada.**(No relevant relationships reported)*

Background: Masters athletes (≥35 yrs) are not immune to elevated cardiovascular risk and cardiac events. In the first year of Masters Athlete Screening Study, 798 masters athletes were screened; 91 (11.4%) of the cohort were found to have cardiovascular disease (CVD). Coronary artery disease (CAD) was the most common diagnosis (7.9%).

Purpose: To evaluate the incidence of CVD and adverse cardiovascular events over four years of the screening study.

Methods: Masters athletes (≥35yrs) from a variety of sports without previous history of CAD underwent yearly cardiovascular screening for four years. The screen consisted of anthropometrics, resting blood pressure, resting electrocardiogram, modified American Heart Association 14-element recommendations, cardiovascular event questionnaire, physical examination (year one), and Framingham Risk Score. Participants with an abnormal screen according to the European Association of Cardiovascular Prevention and Canadian Cardiology Society Guidelines underwent further evaluations.

Results: During the following three years of study an additional 45 cases of CVD were detected, with an incidence rate of 1.9/100 (64.7±7.3yr; 79%M), 3.0/100 (65.1±7.3yr; 62%M), and 1.5/100 (65.0±5.8yr; 80%M), for years two, three, and four, respectively. Twelve participants had a new CVD diagnoses or progression of a diagnoses. The most common diagnoses over the three years was CAD (n=15; 33.3%) and atrial arrhythmias (n=14; 31.1%). An additional 9 participants were diagnosed CVD outside of the study (atrial fibrillation n=2; moderate CAD n=2; mild CAD n=4; genotype positive hypertrophic cardiomyopathy n=1). Five out of 798 (0.6%) participants had a myocardial infarction. A single CV death occurred. Three of the individuals who had a cardiac event demonstrated a negative exercise treadmill test (ETT) (mean time 15±2.9 min) and three had a positive ETT (mean time 12±1.2 min); two of which initiated cholesterol-lowering medication after confirmation of CAD via CCTA, and one declined medication after a negative MIBI.

Conclusion: Yearly cardiovascular screening of masters athletes identified ~2 new diagnoses per 100 athletes per year (primarily CAD and atrial fibrillation). Despite yearly cardiovascular screening and high fitness, myocardial infarctions still occur.

2416 Board #5 May 28 6:00 PM - 7:00 PM

Sex Differences In Patient Reported Outcomes 6 Months Following Acl ReconstructionEmily Kidwell, Cale Jacobs, Mary Lloyd Ireland, FACSM, Darren Johnson, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.**(No relevant relationships reported)*

Evidence indicating the important role psychological factors contribute to patient reported outcome (PROs) post anterior cruciate ligament reconstruction (ACLR) has been growing over the last decade. However, it is unclear whether sex-specific differences in psychological profile exist in ACLR recovery. Determining the potential psychological differences between sexes has important implications on the development of targeted intervention strategies post ACLR. **PURPOSE:** To determine whether sex differences in PROs exist at six months following ACLR.

METHODS: Forty-one subjects (23 F, BMI 24.0 ± 3.5, Age 19.2 ± 5.9, Tegner 8.8 ± 1.2) six months post ACLR completed PRO questionnaires. Subjects were administered the ACL-Return to Sport after Injury Scale (ACL-RSI), the Knee Self-Efficacy Scale (K-SES), and the Psychological Readiness to Return to Sport Scale (I-PRRS). Independent samples t-tests were used to compare PRO responses between males and females.

RESULTS: No significant differences were observed between male and female demographic information (p > 0.05). Significant differences were observed between male and female responses. Males reported higher scores on the ACL-RSI (M: 7.63 ± 1.43, F: 5.46 ± 2.17; p = 0.004, Cohen's d = 1.21), K-SES8 (M: 8.88 ± 0.85, F: 7.53 ± 2.11; p = 0.001, Cohen's d = 0.88), and I-PRRS (M: 51.58 ± 6.22, F: 36.17 ± 13.37; p < 0.001, Cohen's d = 1.54) when compared to females.

CONCLUSIONS: These results show that, six months following ACLR, males have significantly higher knee-function self-efficacy, as assessed by K-SES. I-PRRS and ACL-RSI responses show that males are more psychologically ready to resume sports participation. These results show a discrepancy between male and female psychological response following ACLR, which should be a consideration for re-injury risk. While most patients are cleared to return to activity six to nine months

post ACLR, there is a lack of consideration for patient's psychological readiness at the time, for both sexes. If females are returning to sports before being psychologically ready, they are likely to be hesitant and less confident in game situations, contributing to injury risk. Future work is needed to determine if psychologically-focused rehabilitation programs are needed to potentially reverse the reported sex differences.

Diarrhea (Infectious Disease)-Swimming And Diving

Jordan P. Hilgefert, Christina Murphy, Amy Miller, Keri Denay, FACSM. *University of Michigan, Ann Arbor, MI.*
 (No relevant relationships reported)

History: 19-year-old men's collegiate swimming athlete with PMH of anxiety & major depressive disorder presented with 3-days of nausea, vomiting & diarrhea. He reported several teammates with similar symptoms. He returned for reassessment 1 week following initial evaluation endorsing 2 days of symptom improvement followed by return of several episodes of emesis, diarrhea & fatigue.

Physical Examination:

General: Well-developed, Well-nourished, NAD

HEENT:

-Head: NC, AT

-Eyes: conjunctiva clear, EOMI, PERLL, no discharge

-Ears: hearing normal on gross assessment, TMs normal

-Nose: nares clear, no deformity

-Throat: MMM, no erythema or exudate

NECK: normal ROM, no lymphadenopathy

PULM/CHEST: CTAB, no wheezes, rales or rhonchi

CV: RRR, no MRG. CR < 2 sec

ABD: BS+, soft, non-tender, non-distended, no organomegaly

SKIN: no visualized rashes or skin lesions, skin is warm and dry

PSYCH: appropriate mood and affect

Differential Diagnosis:

- 1) Viral gastroenteritis
- 2) Bacterial gastroenteritis
- 3) Parasitic infection
- 4) Irritable bowel syndrome
- 5) Anxiety

Tests and Results: Initial CBC, BMP and TSH were remarkable only for mild thrombocytosis (447 K/mm³) and hypoglycemia (63 mg/dL). After incomplete resolution of symptoms, GI PCR panel was obtained and found to be positive for cryptosporidium.

Final Diagnosis: Cryptosporidiosis

Treatment and Outcomes:

- 1) He was treated with Nitazoxanide 500 mg PO BID x 3 days and held out of the pool for 2 weeks.
- 2) Athletes with exposure to university pools presenting with diarrhea were tested for cryptosporidium via PCR. 6 were positive and all were held out of the pool for 2 weeks.
- 3) The public health department and environmental health experts were consulted to assist with management.
- 4) Administrators from every university and local swimming clubs who shared a common pool with our athletes were notified of potential exposure to cryptosporidium. One head-to-head swimming meet was cancelled in an effort to limit potential exposure.
- 5) University pools were shut down and treated twice with a high-concentration chlorine.
- 6) Water samples were collected serially before and after treatment cycles to ensure eradication prior to re-opening the pools.

2418 Board #7 May 28 6:00 PM - 7:00 PM
Rare Case Of Avascular Necrosis In A Dodgeball Player

Steven Liu¹, Alpha Anders², Kenneth Vitale, FACSM². ¹*Eastern Virginia Medical School, Norfolk, VA.* ²*UCSD School of Medicine, San Diego, CA.*
 (No relevant relationships reported)

History:

A 27-year-old male presented with left anteromedial hip/groin pain for 2 weeks. He competes in a dodgeball league and plays occasional racquetball as well. After a dodgeball game, he noted onset of hip and groin pain, which became progressively severe, and went to a local Emergency Department. He had x-rays and were told they were normal, however he had significant pain even with weightbearing at this point. No past history of hip dysplasia, dislocation, hip surgery.

Physical Examination:

Hip flexion was 110°, internal rotation 20°, external rotation 60°, abduction 45°; significant pain with flexion, adduction, and internal rotation, and positive FABER. He was able to ambulate without assistance.

Differential Diagnosis:

- Labral tear
- Femoroacetabular impingement
- Femoral neck stress fracture
- Loose body
- Chondral defect
- Athletic pubalgia

Tests and results:

X-rays were obtained and suggested minimal left femoral head collapse, and did suggest mild right femoral head sclerosis; an MRI showed large areas of grade 2 avascular necrosis bilaterally. The left had a joint effusion, edema in addition to necrotic fatty signal in the femoral head compatible with early collapse.

Final/Working Diagnosis:

Bilateral hip avascular necrosis with early left collapse.

Treatment/Outcome:

- Internal Medicine and Rheumatology referral for serological work up.
- Referred to Orthopedic Surgeon; recommended toe-touch weightbearing, counseled on risk of progression. Alendronate was considered as with precollapse Ficat stages 0-II.
- At 8 months, left hip pain was progressing, and noted onset of right hip pain. X-rays showed visible left AVN on the entire weightbearing surface with collapse and flattening of the superior articular surface; right hip now showed subtle sclerosis.
- His only pertinent history included a brief course of oral corticosteroids when he got his wisdom teeth removed, which he did not initially disclose. This case reports an unusual etiology of an avascular necrosis after taking a short-term dose of corticosteroids. Case raises awareness to counsel health providers about collaborating to provide patients with optimal care and avoid potential serious side effects.

2419 Board #8 May 28 6:00 PM - 7:00 PM

Bilateral Hip Pain - Soccer Player

Samantha Lucrezia (Sponsor: Dilipkumar R. Patel, FACSM), Danielle Hirsch, Patrick Mularoni. *Johns Hopkins All Children's Hospital, St. Petersburg, FL.*
 (No relevant relationships reported)

History: A 16-year-old Asian male presented with 2 weeks of worsening groin pain. Pain began after a difficult soccer practice, without a specific inciting injury. Patient was evaluated by team's athletic trainer and was referred to orthopedic surgery where x-rays were negative. One week later, patient presented to local pediatric emergency center with intermittent fevers, worsening pain and inability to ambulate. He denied any recent travel outside the US or new exposures.

Physical Exam: afebrile in no acute distress with tenderness to palpation over paraspinal muscles, costovertebral processes L3-L4 and quadriceps musculature. Patient walked with antalgic gait and found to have 2/5 strength hip flexion bilaterally with 5/5 strength in all other muscle groups. Cardiac, pulmonary and abdominal exam were unremarkable. There was no lymphadenopathy present on exam.

Differential Diagnosis:

1. Ankylosing Spondylitis
2. Iliopsoas Abscess
3. Epidural abscess
4. Osteomyelitis
5. Malignancy

Test and Results:

- ESR: elevated at 94 mm/hr, CRP: elevated at 4.57 mg/dL
- CBC: mild normocytic anemia without leukocytosis or thrombocytopenia
- CK, CMP, Uric Acid, LDH within normal limits
- Blood culture: negative
- Rheumatologic studies: ANA, adolase, ANCA were negative
- Testicular US: negative

-MRI of lumbar spine and pelvis: signal enhancement within the bones of pubis symphysis with significant surrounding soft tissue edema
 -Bone biopsy: focally degenerated bone, mixed chronic inflammation, fibrosis with reactive changes. No microorganisms present on special stains

- Bone aerobic/anaerobic cultures: negative
- Quantiferon gold: POSITIVE, mycobacterium sputum PCR: POSITIVE
- Chest x-ray: negative

Final/Working Diagnosis:

Tuberculosis osteomyelitis of the pelvis

Treatment and Outcomes:

1. Treatment with ethambutol, isoniazid, pyrazinamide, and rifampin daily until cleared by infectious disease
2. Close follow up with Infectious disease clinic with monitoring labs every 2 weeks
3. Indomethacin PRN for pain
4. Range of motion and strengthening exercises for bilateral hip flexors with physical therapy
5. Regular follow up with local department of health

2420 Board #9 May 28 6:00 PM - 7:00 PM

Head Injury - Soccer

Mark Sederberg (Sponsor: Stanley Herring, FACSM), Melinda Loveless. *University of Washington, Seattle, WA.*
(No relevant relationships reported)

HISTORY:

A 16 year-old male presented to an outpatient sports medicine clinic one month after a head-to-head collision during a soccer match with concern for concussion. There was no loss of consciousness, and he continued to play the rest of the game with a mild headache. He felt normal and asymptomatic that evening and was able to complete homework. The following morning he felt tired, but was able to perform adequately at school. Over the coming weeks, he noticed progressive worsening of his cognitive symptoms and tiredness. His athletic trainer became concerned for a concussion and held him from practice. One week prior to presentation he noted midline lower lip numbness, teeth pain while chewing, hearing his pulse in his left ear, and poor sleep due to sweatiness. He also felt progressive lethargy and difficulty concentrating and missed the last three days of school due to these symptoms. His medical history was significant only for a recently diagnosed inguinal hernia.

PHYSICAL EXAMINATION:

Mild cognitive deficits in attention and memory, impaired balance on BESS, normal motor strength. Cranial nerve exam showed ptosis of the left eye, mild left facial nerve palsy, decreased hearing in the left ear, and altered sensation to light touch over the middle lower lip. There was no focal tenderness or deformity of the skull or scalp.

DIFFERENTIAL DIAGNOSIS:

Mild traumatic brain injury

Intracranial hemorrhage

Cerebral mass

Bell's palsy

TESTS AND RESULTS:

MRI Brain with and without contrast: Asymmetric enhancement of the left 7th cranial nerve, asymmetric nodular enhancement along the left 5th nerve with enhancement of muscles of mastication, diffuse bilateral pachymeningeal enhancement.

Complete Blood Count: WBC 19k, platelets 80, hematocrit 30.4

CT Chest, Abdomen, Pelvis: Large abdominal soft-tissue mass herniating through the inguinal canal, most consistent with a lymphoma

CSF Cytology: Enlarged B-cells most consistent with Burkitt lymphoma.

FINAL DIAGNOSIS:

Stage IV Burkitt lymphoma, with primary lesion in abdomen, and perimeningeal spread, causing cranial nerve V and VII palsies.

TREATMENT AND OUTCOMES:

1. Admitted for prompt initiation of chemotherapy.
2. Cranial nerve symptoms resolved with chemotherapy and steroids.
3. After multiple rounds of chemotherapy, there is no evidence of residual lymphoma.

2421 Board #10 May. 28 6:00 PM - 7:00 PM

Do Different Wet Bulb Globe Temperature Reading Cutoffs Change Outdoor Heat Injury Frequency And Severity?

Christina S. Gutta (Sponsor: Dr. Franklin Sease, FACSM)¹, Ellen E. Shanley², Vicki R. Nelson¹. ¹*Prisma Health, Greenville, SC.*
²*ATI Physical Therapy, Greenville, SC.*
(No relevant relationships reported)

PURPOSE: To evaluate differences in injury frequency and severity between two different heat participation policies in South Carolina high school and collegiate athletics.

METHODS: Retrospective cohort study of Division II collegiate & high school athletes looking at injury frequency & severity between 2 different heat participation policies. Fifty middle & high schools as well as 2 Division II colleges with a total of 16,832 athletes were investigated over 3 years. Inclusion criteria were reported heat illnesses between July 1 & November 30th for 12 outdoor sports resulting in 86 injuries that were analyzed. Chi square analysis was used to compare injury frequency & severity between no outdoor workouts with a wet bulb globe temperature (WBGT) > 90 (policy 1) versus WBGT > 92 (policy 2).

RESULTS: For policy 1 there was a mean of 31 heat illnesses/year with an average of 16 days for illness resolution. For policy 2 there was a mean of 24 heat illnesses/year but the average of 41 days for illness resolution was significantly higher (p=0.02). Grading heat illness severity was based on guidelines developed by Rauh et al. Mild to moderate injury was defined as 0-21 days for return to activity while severe injury >21 days for return to activity. With policy 1, 4.8% of heat illnesses met severe criteria while 20.8% of heat illnesses in policy 2 were severe showing an odds ratio of heat illness with policy 2 is 5.2 times higher than policy 1 (OR 5.2, 95% CI 1.1-23.7). Conversely the percentage of mild to moderate illness was statistically lower with policy 2 compared to policy 1 (p=0.022) suggesting that policy 2 resulted in more severe heat illness. Policy 1 was in place for several years with no record of EMS transport for heat illnesses however within the first season of policy 2, there

was 3 athletes transported. The average age at time of injury was 16 years old & not statistically different between policies. There was an average of 45 minutes of practice per week lost with the WBGT cutoff of 90 compared to cutoff of 92.

CONCLUSIONS: Although the total number of heat illnesses did not change between policies, there was a statistically significant increase in severity of illness & time for return to sport with raising the WBGT participation cutoff from 90 to 92. Our data suggests that a cutoff of 90 reduces the frequency of severe heat illness in athletes.

2422 Board #11 May 28 6:00 PM - 7:00 PM

International Clinical Scholar Award - Results From The Fifa Sudden Death In Football Registry (FIFA-SDR) — Sport-specific Data Of 5 Years

Florian Egger¹, Jürgen Scharhag, FACSM², Andreas Kästner³, Jiri Dvorak⁴, Philipp Bohm⁵, Tim Meyer, FACSM¹. ¹*Saarland University, Saarbrücken, Germany.* ²*University of Vienna, Vienna, Austria.* ³*University Heart Center Freiburg, Bad Krozingen, Germany.* ⁴*Schulthess Clinic, Zurich, Switzerland.* ⁵*University Heart Center of Zurich, Zurich, Switzerland.*
(No relevant relationships reported)

PURPOSE: Large population-based studies about sudden cardiac deaths (SCD) and survived sudden cardiac arrests (SCA) in athletes from the USA and Europe indicate regional differences in the underlying causes. A different ethnic and genetic mix between these regions may lead to such a heterogeneous distribution. It is of great relevance to investigate these regional patterns to possibly optimize existing screening and prevention procedures and reduce fatalities. This registry aims to investigate SCD and SCA in football (soccer) players worldwide, both at professional and recreational level.

METHODS: From 2014 to 2018 cases of SCDs and SCAs were mainly recorded by media monitoring (Meltwater®), a confidential web-based data platform and data synchronization with existing national SCD registries (n=16). Inclusion criteria were met when SCD or SCA occurred during football-specific activity or up to one hour afterwards. Death during other activities was excluded.

RESULTS: A total of 632 players (mean age 34 ± 16 years, 96% males) was reported from 70 countries; 150 players (24%) survived. Elite players represented a small portion (6%). A diagnosis by autopsy or definite medical reports could be established in 219 cases (35%). The leading causes over the age of 35 years were coronary artery disease (CAD, 74%) and ≤35 years sudden unexplained death (22%), cardiomyopathy (CM, 17%) and CAD (11%). Hypertrophic CM and coronary artery anomalies showed the highest fraction in North America with 15% and 36%, respectively. Myocarditis was most frequently reported from Europe (7%). CAD ≤ 35 years prevailed in Africa (38%) and CM (42%) in South America. Commotio cordis occurred infrequently (3%). In North America and Australia survival rates were the highest (53% and 47%, respectively). Early use of an automated external defibrillator was associated with a higher survival rate (86%) compared to manual cardiopulmonary resuscitation (35%). **CONCLUSIONS:** Differences between countries in the underlying cardiac diseases for SCA and SCD have to be taken into account to possibly improve and modify primary and secondary prevention measures in football players. The percentage of autopsied cases is difficult to increase because this reflects the law in most countries. Therefore, an expansion of national SCD registries is urgently needed.

2423 Board #12 May. 28 6:00 PM - 7:00 PM

Lisa S. Krivickas Clinician/Scholar Travel Award: The Diagnostic And Prognostic Utility Of Dual-task Tandem Gait For Pediatric Concussion

Katie A. Van Deventer, Corrine N. Seehusen, Gregory A. Walker, Julie C. Wilson. *Children's Hospital Colorado, Aurora, CO.*
(No relevant relationships reported)

Background: Tandem gait performance is part of the Sports Concussion Assessment Tool (SCAT), but its diagnostic and prognostic value has not been fully assessed in pediatric concussion. **Purpose:** To determine the diagnostic and prognostic value of single-task and dual-task tandem gait by comparing performance of subjects with concussion relative to controls, as well as subjects who developed Persistent Post Concussion Symptoms (PPCS) and those who did not (No PPCS). **Methods:** Subjects seen within 21 days of concussion and uninjured controls completed a single/dual-task tandem gait test battery and modified Balance Error Scoring System (mBESS) test. During the tandem gait test, subjects walked in a heel-toe manner along a 3m strip of fabric down and back as fast as possible. During dual-task trials, they completed a concurrent cognitive task. Outcomes included tandem gait time to completion, cognitive accuracy, and mBESS errors. Subjects with concussion were followed until symptom resolution and sub-grouped into those who developed PPCS (>28 d time to symptom resolution) vs. No PPCS. **Results:** We evaluated 29 subjects with concussion who developed PPCS (mean age=15±2 years; 62% female; tested 12±6 days post-injury), 58 subjects with concussion who did not develop PPCS (mean age=14±3 years; 36% female; tested 8±5 days post-injury), and 58 controls (mean age= 16±1 years; 42% female). Subjects with concussion performed significantly worse than

healthy controls on single-task tandem gait (24.4 ± 12.6 vs. 14.9 ± 3.6 s; $p < 0.001$; area under curve [AUC]=0.85), dual-task tandem gait (33.3 ± 14.9 vs. 20.6 ± 7.1 s; $p < 0.001$; AUC=0.84), dual-task cognitive accuracy (82.1 ± 12.5 vs. 89.1 ± 18.9 %; $p = 0.01$; AUC=0.61), and mBESS (6.5 ± 4.9 vs. 3.8 ± 3.4 errors; $p = 0.001$; AUC=0.68). The PPCS sub-group performed dual-task tandem gait significantly slower than the No PPCS group (38.8 ± 17.7 vs. 30.6 ± 12.7 s; $p = 0.016$; odds ratio=1.04), but PPCS and No PPCS groups were not significantly different on other measures. **Conclusions:** Pediatric patients with concussion have impaired performance on balance and gait measures compared to healthy controls. Dual-task tandem gait test specifically showed diagnostic value for pediatric concussion and prognostic value in differentiating subjects who developed PPCS compared to those who did not.

E-06 Thematic Poster - Buffers

Friday, May 29, 2020, 9:30 AM - 11:30 AM

The Efficacy Of Topical Sodium Bicarbonate Application On Blood Buffering Capacity And Exercise Tolerance

Rebecca L. Cross¹, Alannah McKay², Peter Peeling², Martyn Binnie³, Paul Goods², Marc Sim⁴, Jason Siegler, FACSM¹.
¹Western Sydney University, Penrith, Australia. ²University of Western Australia, Crawley, Australia. ³Western Australian Institute of Sport, Mt Claremont, Australia. ⁴Edith Cowan University, Western Australia, Australia. (Sponsor: Jason Siegler, FACSM)
Email: r.cross@westernsydney.edu.au
Reported Relationships: **R.L. Cross:** Industry contracted research; AMP Human.

The ingestion of sodium bicarbonate (NaHCO₃) to improve short duration, high intensity exercise performance is widely practiced in elite athletics, rowing and track cycling. However, gastrointestinal (GI) distress is a common side-effect of NaHCO₃ supplementation which has been suggested to mitigate the performance-enhancing potential of NaHCO₃ supplementation. With this in mind, a method of NaHCO₃ administration that bypasses the GI tract may be a favourable alternative to oral supplementation. **PURPOSE:** The purpose of this study was to compare the blood buffering profile and exercise responses between a commercially available topical NaHCO₃ lotion and a typical, orally ingested amount (0.3 g/kg body weight (BW) NaHCO₃). **METHODS:** 10 recreationally active participants completed two experimental trials (randomised and counterbalanced); oral NaHCO₃ (0.3g/kg BW + placebo lotion) or topical NaHCO₃ lotion (0.9036 g/kg BW + oral placebo) applied or ingested 90 min prior to a cycling task to exhaustion (repeat 30 s cycling efforts at 120% peak power output with 30 s rest). Capillary blood was collected and analysed for pH, bicarbonate (HCO₃⁻) and lactate every 10 min throughout the 90 min loading period and post-exercise at 5, 10 and 15 min. **RESULTS:** pH and [HCO₃⁻] were significantly elevated from baseline after 10 min in the oral NaHCO₃ condition and throughout recovery compared to the topical lotion ($p < 0.001$). No differences in cycling performance (e.g. cumulative time) were observed between the oral NaHCO₃ condition (363±80s) and topical NaHCO₃ lotion condition (349 ± 119 s; $p = 0.697$). **CONCLUSION:** Topical NaHCO₃ lotion (0.9036 g/kg BW) did not significantly increase blood buffering capacity, suggesting that concentrations used in the present study have limited transdermal absorption capacity into the wider circulation.

2447 Board #2 May 29 9:30 AM - 11:30 AM
Effects Of Chronic Bicarbonate Supplementation On Kicking Performance In Highly Trained Taekwondo Athletes

Gloria Velasquez¹, Oscar Cajbon², Manuel Alvarez², Tanuj Wadhi³, Luis del Valle¹. ¹Confederación Deportiva Autónoma de Guatemala, CDAG/Comité Olímpico Guatemalteco, COG, Guatemala, Guatemala. ²Federación Nacional de Taekwondo de Guatemala, Guatemala, Guatemala. ³University of Tampa, Tampa, FL.
Email: gloriavelasquez@yahoo.com
(No relevant relationships reported)

It has previously been observed that a competitive full-contact Taekwondo combat simulation produced progressively increasing blood lactate concentrations up to 12.3 mmol·L⁻¹ by the third round, resulting in an increment of hydrogen ions (H⁺) which causes fatigue and performance impairment. Chronic bicarbonate (BI) ingestion has been shown to act as an extracellular buffer agent of H⁺, improving performance during intense exercise. **PURPOSE:** Determine the effect of chronic BI supplementation on kicking performance in highly trained athletes during a taekwondo intermittent kick field test (TIKT). **METHODS:** A single-blinded, randomized, crossover study was conducted over 6 weeks on 14 athletes from the Guatemalan national taekwondo team (ages: 17.2±3 yrs). Athletes performed TIKT in pairs, with heart rate monitors and electronic chest protectors. During TIKT, athletes strived for the maximal number of kicks (NK), alternating with their partner for 10s, interspersed with 10s of active

recovery, all during 4 rounds of 2 min x 1 min of rest. Five days before the trials, athletes took 0.3g/kg of either BI or placebo (PL) (maltodextrin + NaCl) divided in 3 doses taken 90, 60 and 30 min before a training session and before TIKT. **RESULTS:** For kicking performance, there was a significant main condition effect ($p \leq 0.05$) in which BI increased NK compared to control (CL) (estimated differences (ED): 16.1). The same was true for the theoretical score, BI vs CL (ED: 32). Although there was a greater NK with BI, there were no significant differences ($p \geq 0.05$) between BI vs PL (ED: 7.5). There was a main condition effect ($p \leq 0.05$) in which BI and PL produced lower mean heart rate compared to CL (BI, ED: 10.9 and PL, ED: 9.8). Post TIKT lactate values were similar ($p \geq 0.05$) in both BI and PL. There were no significant differences between groups ($p \geq 0.05$) in kicking effectiveness (combat score divided by theoretical score times 100). **CONCLUSION:** Our data indicate that kicking performance was enhanced in highly trained taekwondo athletes when chronically supplementing BI by increasing number of kicks but not effectiveness during a TIKT. Furthermore, from a practical point, while not significant, the improvement in other variables with BI (especially the combat score), could potentially be the difference between standing on the podium or not.

2448 Board #3 May 29 9:30 AM - 11:30 AM
Changes In Cognition During A 24-h Simulated Military Operation. Role Of Classical Monocytes And Beta-alanine.

Adam J. Wells¹, Alyssa N. Varanoske¹, Nicholas A. Coker¹, Gregory J. Kozlowski¹, Yftach Gepner², Cheyanne L. Frosti¹, David Boffey¹, Idan Harat¹, Jay R. Hoffman, FACSM³.
¹University of Central Florida, Orlando, FL. ²Tel Aviv University, Tel Aviv, Israel. ³Ariel University, Ariel, Israel.
(Sponsor: Jay Hoffman, FACSM)
(No relevant relationships reported)

Cognitive dysfunction during sustained military operations (SUSOP's) may be related to the recruitment and infiltration of classical monocytes into the brain. Beta-alanine (BA) supplementation may attenuate cognitive dysfunction and improve resilience to stress exposure, which may be relevant during a SUSOP. **PURPOSE:** To examine the effect of BA on serum monocyte chemoattractant protein-1 (MCP1), C-C chemokine receptor 2 (CCR2), macrophage-1-antigen (CD11b) and cognition (COG), and to examine the relationships between these variables during a SUSOP. **METHODS:** Nineteen recreationally active men ingested 12g·day⁻¹ BA ($n = 10$) or placebo (PL; $n = 9$) for 14-days prior to completing a simulated 24-h SUSOP. MCP1 was assessed via multiplex assay. Classical monocyte CCR2 and CD11b expression were assessed via flow cytometry. Throughput (TP) scores were extracted from seven cognitive subtests administered via Automated Neuropsychological Assessment Metric (ANAM) software. The relative weight of each ANAM subtest was determined by dividing its outer weight by the standard deviation of all TP scores for that subtest. TP scores were multiplied by their relative weights, and the values summed to provide a value for COG. Assessments occurred at baseline (0H), 12-hours (12H), 18-hours (18H) and 24-hours (24H). A two-way mixed ANOVA was used to assess differences between BA and PL. The statistical significance of pathway (β) coefficients derived from partial least squares structural equation modeling were used to evaluate relationships between MCP1, CCR2, CD11b and COG. **RESULTS:** MCP1 was significantly greater at 12H, 18H and 24H relative to 0H ($p < 0.001$). CCR2 expression was significantly lower at 12H ($p = 0.031$), 18H and 24H ($p < 0.001$), while CD11b expression was significantly greater at 12H ($p = 0.039$) and 24H ($p = 0.003$) relative to 0H. COG was significantly lower at 18H and 24H compared to 0H and 12H ($p \leq 0.001$). No significant differences were noted between BA and PL for any variable ($p > 0.05$). MCP1 had a direct negative relationship with cognition ($\beta = -0.395, p = 0.002$). CCR2 and CD11b were not directly related to cognition ($p > 0.50$). **CONCLUSIONS:** Greater serum MCP1 concentrations were associated with increased cognitive dysfunction during the SUSOP. BA did not affect MCP1, CCR2, CD11b or COG compared to placebo.

2449 Board #4 May 29 9:30 AM - 11:30 AM
Effect Of Beta-alanine Supplementation On Transporters Gene Expression And Long Distance Runner Performance.

Gabriel S. Franco, Bruno A. F. de Oliveira, Flávia C. Ferreira, Natalia Y. Noronha, Ana Paula Pinto, Camila F. C. Brandao, Carla B. Nonino. *University of São Paulo, Ribeirão Preto, Brazil.*
Email: gabriel_franco85@hotmail.com
(No relevant relationships reported)

Purpose: To evaluate the effect of beta-alanine supplementation in carnitine transporters gene expression (*TauT* and *PATI*) and physical performance in athletes (long-distance runners). **Methods:** This double-blind randomized study enrolled sixteen males athletes (37 ± 8 years) divided into two groups: Placebo group (PLA), received starch (6 capsules/day) and Beta Alanine group (BA), received beta-alanine

(4.8 g per day fractionated into 6 capsules/day) for 4 weeks. Before intervention, anthropometry (weight and height), body composition (seven skinfold protocol), food intake (24-hour recall) and maximal treadmill test (Vo2Max) data were evaluated. Before and after intervention, the athletes were submitted to physical performance test (5-km race time trial), venous blood was collected for analysis of *TauT* and *PAT1* gene expression (*RT-qPCR*) and ear lobe capillary blood was collected for lactate and glucose analysis before (T_0) and post-test (T_1), three (T_3), five (T_5) and seven (T_7) minutes after the end of the test. Data are expressed as mean \pm standard deviation. Statistical analysis was performed using normality test (Shapiro-Wilk), t-tests (paired and independent), and repeated measures analysis of variance (ANOVA). Significance was accepted at p value lower than 0.05. **Results:** In the beginning of the study BA group presented higher body fat than PLA group (11.5 ± 2.8 vs. $8.7 \pm 2.2\%$, $p=0.04$). No differences in others parameters was observed. After supplementation, there was an increase in *PAT1* expression in BA group when compared to PLA group (1.17 ± 0.47 vs. 0.77 ± 0.18 , $p=0.04$). No changes were observed for *TauT* expression (0.68 ± 0.33 vs. 0.39 ± 0.17 , $p=0.08$). No statistical differences were found in performance 5km tests time in BA group (1107 ± 95 vs. 1093 ± 86 seconds) and PLA group (1128 ± 72 vs. 1123 ± 72 seconds). However, there was 14 seconds decrease in the BA group. There was an increase in lactate and blood glucose between T_0 and the other times in both groups. **Conclusion:** Beta-alanine supplementation for four weeks increases *PAT1* gene expression. No statistical significance in performance improvement in 5-km test performance was observed. However, the 14 seconds time improvement in performance, suggests that some competitive athletes could benefit from supplement intervention.

No relationships reported.

2450 Board #5 May 29 9:30 AM - 11:30 AM
Does Acute Beta-alanine Supplementation Improve Performance, Rating Of Perceived Exertion And Heart Rate During Hiking?

Bryson Carrier. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: James Navalta, FACSM)
 (No relevant relationships reported)

Beta-Alanine (BA) is a common performance supplement and is thought to work by increasing the muscle buffering capacity by increasing carnosine levels, thereby decreasing muscle fatigue. The performance benefits of chronic BA supplementation has been well established while the acute effects are less resolved. It has been hypothesized that BA has a stimulatory effect, a common justification of its use in pre-workout supplements, though this has yet to be established in the published literature. **PURPOSE:** To determine if acute supplementation with BA improves performance, decreases ratings of perceived exertion, or stimulates the sympathetic nervous system during a short hike. **METHODS:** 11 subjects (2 female, 9 male, 26.18 ± 8.17 yrs [mean \pm stdev], 78.68 ± 11.95 kg, 176.18 ± 10.67 cm) participated in a double-blind crossover study, taking either a homogeneous solution of 6.4g BA and crystal light (placebo) or the placebo (PLA) in 8oz of water. After the solution was consumed, a 45-min interim was observed to ensure proper metabolism of the supplement. The participants then completed a 0.81 km (0.5 mile) hike on the Lightning Switch trail (Cedar City, UT, elevation gain = 66m, 217 ft) as fast as possible, without running. RPE and HR were recorded at the start and end of the hike, using the Borg 6-20 scale for RPE. The participants completed the alternate supplementation on the following day. A random number generator was utilized to assign which day participants would receive BA or the PLA. Data analysis was completed looking at performance under each supplement condition using a 2 tailed paired t-test for time and bottle. HR and RPE analysis was completed utilizing a 2x2 repeated measures ANOVA. Significance was accepted at an alpha of 0.05. **RESULTS:** There was no difference found in performance between supplement conditions (BA hiking time = 8.39 ± 1.34 , PLA Hiking Time = 8.58 ± 1.57 , $p=0.26$). For all dependent variables, no interaction was observed (HR $p=0.27$; RPE $p=0.63$; Time $p=0.26$). For HR and RPE, there was a main effect in regards to time (HR Pre = 80.73 ± 15.17 , HR Post = 150.86 ± 22.13 , $p<0.001$; RPE Pre = 6.68 ± 0.99 , RPE Post = 14.27 ± 1.98 , $p<0.001$); **CONCLUSION:** Changes in response variables (HR, RPE) are expected due to the exercise. Acute BA supplementation 45-min prior to hiking does not have an effect on performance, RPE or HR.

Acute Beta-alanine Supplementation And Pain Perception Before And After Hiking

James W. Navalta, FACSM¹, Graham R. McGinnis¹, Jacob W. Manning², Robert W. Salatto¹, Bryson Carrier¹, Dustin W. Davis¹, Jacquelyn V.L. Sertic¹, Peyton C. Cater¹, Brenna Barrios¹, Elias M. Malek¹, Caitlin K. Reynolds¹, Mark DeBeliso, FACSM². ¹University of Nevada, Las Vegas, Las Vegas, NV. ²Southern Utah University, Cedar City, UT.
 Email: james.navalta@unlv.edu
 (No relevant relationships reported)

Beta alanine (B-ALA) is a non-essential amino acid thought to increase muscle buffering capacity and decrease muscle fatigue. Supplementation with B-ALA is known to commonly cause paresthesia in some individuals, an unpleasant sensory symptom. It is unknown whether B-ALA supplementation affects pain perception in a natural environment or hiking performance. **PURPOSE:** The aim of this study was to determine if supplemented B-ALA affected participants' perceived pain before and after a bout of hiking. **METHODS:** Participants (N = 11) completed a double-blind crossover study. B-ALA (6.2 g) or placebo (PLA) was administered, followed by 45-min of seated immersion in nature. Participants completed the McGill Pain Questionnaire short form and then completed a 0.81 km (0.5 mile) hike on the Lightning Switch trail (Cedar City, UT) as fast as possible (elevation gain = 66m, 217 ft) before filling out the questionnaire again. Participants completed the alternate supplementation on a separate day. Data was analyzed using a 2 x 2 repeated measures ANOVA with significance accepted at $p<0.05$. **RESULTS:** No interaction was noted for total pain score (PLA pre = 0.6 ± 1.0 , post = 2.8 ± 3.0 ; B-ALA pre = 2.6 ± 3.1 , post = 3.2 ± 4.2 ; $p = 0.08$) or treatment main effect ($p = 0.07$). No interaction was present for the sensory component of pain (PLA pre = 0.4 ± 0.8 , post = 1.7 ± 2.0 ; B-ALA pre = 2.0 ± 2.1 , post = 2.2 ± 2.9 ; $p = 0.13$) but a main effect for treatment was observed ($p = 0.02$). Hiking performance was not different between treatment days (PLA = 8.4 ± 1.3 min, B-ALA = 8.6 ± 1.6 min, $p = 0.27$). **CONCLUSION:** While acute B-ALA increases the sensory perception of pain when administered in a natural environment, it does not affect hiking performance.

Chronic Muscle Inactivity Does Not Affect Muscle Carnosine Loading Induced By Beta-Alanine Supplementation

Kleiner Nemezio¹, Guilherme Yamaguchi², Ana Ramkrapes³, Luiz Riani², Mariane Schulz², Marisa Medeiros², Guilherme Artioli². ¹Estácio-Fal, Maceió, Brazil. ²University of São Paulo, São Paulo, Brazil. ³University of Campinas, Campinas, Brazil.
 (No relevant relationships reported)

PURPOSE: to study the impact of the extremes of muscle activity and inactivity on muscle carnosine content (M_{car}) and M_{car} loading in response to beta-alanine supplementation. **METHODS:** 16 trained male with spinal cord injury (SCI) (ASIA scale: AIS A or AIS B) were divided into 2 groups: beta-alanine (BA) (N = 11) and placebo (PL) (N = 5). Muscle biopsies samples were obtained from active deltoid and paralysed vastus lateralis at baseline and after 28 days of beta-alanine supplementation ($6.4 \text{ g} \cdot \text{day}^{-1}$). Unpaired t-tests were applied to compare M_{car} at baseline and the absolute pre-post change in vastus lateralis and deltoid. Mixed model was used to compare M_{car} values within- and between-subjects. **RESULTS:** (mean \pm SD): Baseline M_{car} concentration in vastus lateralis was significantly higher than in deltoid (32.0 ± 12 vs. $20.5 \pm 6.1 \text{ mmol} \cdot \text{kg}^{-1}$ dry muscle; $p=0.02$). Absolute changes in M_{car} was significantly higher in the BA group in comparison with PL for both vastus lateralis (BA: $17.6 \pm 10.4 \text{ mmol} \cdot \text{kg}^{-1}$ dry muscle; PL: $2.5 \pm 2.3 \text{ mmol} \cdot \text{kg}^{-1}$ dry muscle; $p=0.002$) and deltoid (BA: $15.7 \pm 6.8 \text{ mmol} \cdot \text{kg}^{-1}$ dry muscle; PL: $1.4 \pm 2.7 \text{ mmol} \cdot \text{kg}^{-1}$ dry muscle; $p<0.001$). Absolute changes in M_{car} following BA supplementation between inactive vastus lateralis and active deltoid was not different (vastus lateralis: 17.6 ± 10.4 ; deltoid: $15.7 \pm 6.8 \text{ mmol} \cdot \text{kg}^{-1}$ dry muscle; $p=0.6$). **CONCLUSION:** chronic muscle inactivity due to paralysis in SCI does not affect M_{car} at baseline and does not affect M_{car} loading in response to BA supplementation. These results suggest that muscle activity or training status does not influence M_{car} synthesis capacity in response to beta-alanine supplementation. Supported by CEPID-Redoxoma (São Paulo Research Foundation FAPESP: Proc. 2013/07937-8, and CAPES- PROEX 1888/2016), and FAPESP thematic grant (13/14746-4).

 (No relevant relationships reported)

A recent review has addressed a number of practical issues associated with traditional sodium bicarbonate (NaHCO₃) supplementation approaches, identifying ingestion timing as critical to maximising the potential of this ergogenic medium. Furthermore, contemporary empirical studies have also suggested that adjusting the start of exercise to commensurate with an individual's peak blood buffering response may result in better outcomes in terms of GI distress and exercise performance, however this concept has yet to be investigated in international level athletes. **PURPOSE:** The following study addressed the question of whether or not ingestion timing is critical to time-trial performance (2,000 m rowing time-trial) in elite-level rowers including Pan American, World Champion and Olympic team members) adhering to their own individualised pre-race strategies (e.g. nutrition, warm-up, etc.). **METHODS:** Twenty three (n = 23) elite rowers across two research centres (Canadian Sport Institute Pacific and the New South Wales Institute of Sport) completed three trials (one NaHCO₃ loading profile to determine the individual's time-to-peak blood buffering capacity followed by two randomized experimental trials (Consensus Standard (CON): 2,000 m rowing time trial (TT) performed 60 min post 0.3 g·kgBW⁻¹ NaHCO₃ ingestion; and Individualised Peak (IP): 2,000 m rowing TT performed at the rower's individual peak bicarbonate concentration [HCO₃⁻] (determined from the profiling trial) after ingesting 0.3 g·kgBW⁻¹ NaHCO₃)). **RESULTS:** Significant interaction effects and post hoc comparisons revealed differences between CON and IP at pre-warm up for HCO₃⁻ (mean difference of 2.9 ± 0.4 mmol·L⁻¹ (95% CI 2.0 to 3.8 mmol·L⁻¹); p = 0.02) but not at pre-TT. Performance times were significantly different between CON (369.0 ± 10.3 s) and IP (367 ± 10.5 s) (mean difference 1.5 ± 2.4 s (95% CI 0.5 to 2.6 s); p = 0.007), however given the effect size this difference was likely trivial. **CONCLUSIONS:** The findings of the present study do not support the recent claims that targeting the onset of exercise to commence with an individual's peak blood buffering capacity after NaHCO₃ supplementation is essential to maximise the ergogenicity of this supplement.

E-07 Thematic Poster - Microbiome and Immunity Across the Healthspan

 (No relevant relationships reported)

High-intensity and volume exercise has been associated with decreased immune cells function enhancing viral infections susceptibility. Probiotic supplementation emerges as a strategy to treat metabolic and inflammatory diseases, playing an immune stimulatory role. **PROPOUSE:** We hypothesized that 30 days of probiotic supplementation could strengthen the immune system of marathonists. **METHODS:** 27 male marathonists were double-blind randomized in probiotic (*Bifidum Lactise* (10x10⁹) and *Lactobacillus Acidofilus* (10x10⁹) + 5g maltodextrin/ sachet) and placebo group (5g maltodextrin/ sachet) each athlete took 1 sachet/day for 30 days pre-race. Blood samples were collected 30 days before the race, 1 day before, 1 hour after and 5 days after.

Lymphocytes population were evaluated by immunophenotyping. **RESULTS:** CD3⁺ T cells decreased to both group 1h after and restored to probiotic group at 5 days after (Fig A). CD8⁺ T cells were significant decreased only to placebo group at 1h after (Fig C). CD3⁺CD4⁺CD8⁺ T cells were increased to both groups at 1 day before, decreased after the run and increased again at 5 days after (Fig D), they also presented a negative correlation with age (Fig L), which could be an indicative of MAIT cells. Promyelocytic leukemia zinc finger protein (PLZF) mRNA, the transcription factor higher expressed in MAIT cells, showed similar response as CD3⁺CD4⁺CD8⁺ T cells and RORγt mRNA followed the same pattern (Fig E and F). Probiotic group presented higher IFNγ, IL-1β, IL-6 and TNFα production, under PMA stimulation 30 days before, however it was not maintained among the other times. IL-8 increased to both groups at 1 hour and decreased only in placebo group at 5 days after (Fig G-K). Neither placebo nor probiotic group presented URTI and difference to symptoms incidence or severity. **CONCLUSION:** In conclusion probiotic supplementation have minor impact on lymphocytes, however the marathon race modulates an important class of double negative T cells.

 (No relevant relationships reported)

Mucosal Associated Invariant T (MAIT) cells have properties of both innate and adaptive immunity and are dysregulated in overweight/obese (OW) populations. MAIT cell proportion and number increase after acute exercise in healthy young men, but the effect of acute exercise on MAIT cells in OW women is unknown. **PURPOSE:** To investigate MAIT cell frequency and function after acute exercise, in OW, older women compared to lean controls. **METHODS:** Sedentary, OW women (n=15, 64 y ± 4, 32.9 kg/m² ± 3.69, 21.7 ml/kg/min ± 3.40) completed 25 min of walking at 70-80% heart rate reserve and 2 sets of 8 resistance training exercises. Immune cells were isolated at rest, 0h and 1h post exercise. Cells were stimulated with PMA/ionomycin. Cell frequency and intracellular cytokine expression were determined using flow cytometry. A reference group of lean women (n=8, 64y ± 7, 21.5 kg/m² ± 2.0, 29.8 (ml/kg/min) ± 5.06) provided a resting blood sample. **RESULTS:** Lymphocyte number increased at 0h by 44% ± 41 (p < 0.001) before returning to resting levels at 1h. Compared to lean women, OW women had greater MAIT cell counts (OW 97 ± 99 cells/uL, Lean 27 ± 18, p=0.048) but lower MAIT cell frequencies at baseline (OW 0.4% ± 0.9, Lean 4.1 ± 2.1%, p<0.001). TNFα expression in stimulated MAIT cells was also lower in OW women (OW 79% ± 16%, Lean 98% ± 5% p<0.001). Following acute exercise, there was no change in MAIT cell frequency or absolute number in OW women. TNFα expression increased by 14% ± 34% (p=0.006) at 0h in the OW group. There were no differences in IFNγ expression between groups or with acute exercise. **CONCLUSIONS:** Obesity appears to attenuate the MAIT cell function and increase counts in OW women. Lower baseline TNFα expression suggests these cells have a reduced capacity to respond to stimulation with greater resting MAIT counts potentially being a compensatory response. Acute exercise did not alter MAIT cell counts or frequencies. However, TNFα expression increased with acute exercise, suggesting that exercise may increase MAIT cell sensitivity to mitogenic stimulation. This temporary increase in cell functionality may offset some of the detrimental effects of obesity on MAIT cells but the long-term training effects still need to be determined.

Cellular Immune Response To Acute Endurance Vs. Resistance Exercise—A Randomized Crossover Study

David Walzik, Marit Lea Schlagheck, Niklas Joisten, Christine Koliyama, Wilhelm Bloch, Alexander Schenk, Philipp Zimmer.
German Sport University Cologne, Cologne, Germany.
(No relevant relationships reported)

Exercise-induced alterations of circulating immune cells are well investigated in both healthy and clinical populations. In healthy individuals these alterations are mainly used to depict immunological recovery, while in clinical context the mobilization of immune cells is suspected to improve the course of various diseases (e.g. neoplastic diseases). Therefore, exercise might serve as add-on therapy to conventional therapeutic approaches. Since direct comparisons of the cellular immune response to different exercise types remain sparse, we compared two exercise sessions of clinical application in healthy subjects, to provide basic knowledge of potential differences. **PURPOSE:** To compare the cellular immune response to an acute bout of endurance exercise (EE) and resistance exercise (RE). **METHODS:** 24 healthy men conducted an acute EE (cycling at 60 % of peak power output) and RE session (5 exercises, 4 x 8-10 repetitions at 70 % of 1-repetition maximum) lasting 50 min on separate days. Blood was drawn before (t_0), after (t_1) and 1h after exercise cessation (t_2). Outcomes included counts of leukocytes (LEUK), neutrophils (NEUT), lymphocytes (LYM), LYM subsets (T, B, NK cells) as well as NK cell subsets (CD56^{dim}, CD56^{bright}). Baseline-adjusted ANCOVAs were performed. **RESULTS:** Compared to RE, values of EE were significantly higher at t_1 for LEUK (mean difference between groups (Δ_g) 1.53, $p \leq .001$), LYM (Δ_g 1.04, $p \leq .001$), NEUT (Δ_g 0.19, $p \leq .001$), T cells (Δ_g 0.49, $p \leq .001$), NK cells (Δ_g 0.45, $p \leq .001$), CD56^{dim} (Δ_g 0.4, $p \leq .001$) and CD56^{bright} (Δ_g 0.05, $p \leq .001$). Regarding LYM subsets, EE caused a significant increase from t_0 to t_1 in T cells (mean difference between time points (Δ_t) 0.59, $p \leq .001$) and B cells (Δ_t 0.05, $p = .001$), while NK cells increased after both, EE (Δ_t 0.58, $p \leq .001$) and RE (Δ_t 0.16, $p = .019$). **CONCLUSION:** An acute bout of EE is superior to RE in mobilizing immune cells. While the cellular immune response of T and B cells seems to be reserved to EE, RE does represent an appropriate stimulus for NK cell mobilization. Thereby, our results indicate that especially in neoplastic diseases where NK cell mobilization is crucial, RE might represent a suitable alternative to EE as potential add-on therapy to conventional therapeutic approaches. However, validation of our results in diseased populations is warranted.

Simpson, FACSM¹. ¹University of Arizona, Tucson, AZ. ²Huntsman Cancer Institute, Salt Lake City, UT. ³University of Texas MD Anderson Cancer Center, Houston, TX. ⁴University of Houston, Houston, TX. (Sponsor: Dr. Richard J Simpson, FACSM)
 Email: graceniemi@email.arizona.edu
(No relevant relationships reported)

Aging causes changes in the peripheral T-cell compartment that may increase susceptibility to cancer and lower immune responses. Fitness is associated with lower frequencies of highly differentiated T-cells, increased naïve T-cells, and elevations in myokines such as IL-7 that contribute to naïve T-cell output, indicating that exercise may help preserve immunity. **PURPOSE:** Examine the impact of exercise training on the differentiation status of CD4+ and CD8+ T-cells, recent thymic emigrants (RTE), and plasma levels of IL-7 in older women with an elevated risk of breast cancer (obesity status, postmenopausal, elevated Gail and/or lifetime risk score or history of non-invasive breast cancer).

METHODS: 44 women (VO_{2max} = 19.58±3.37 ml/kg/min) were randomized to: high-intensity interval training (HIIT; n=16; 63.73±6.86yrs); moderate continuous exercise (MCE; n=14; 64.62±12.21yrs); or control (CNT; n=14; 63.35±6.99yrs). Participants completed clinically supervised treadmill exercise 3x/week for 12 weeks using heart rate training. Naïve (NA), central memory (CM), effector memory (EM) and CD45RA+ effector memory (EMRA) CD4+ and CD8+ T-cells, and RTE (CD4NA or CD8NA CD31+CD103+) in blood were quantified before and after training. Fold changes (cells/ul) were calculated by (post-pre)/pre and compared across groups via ANOVA with $p < .05$ considered significant.

RESULTS: 11, 10, and 11 participants completed the HIIT, MCE, and CNT training, respectively. Compared to HIIT, MCE increased total lymphocytes (-0.05±0.13 vs. 0.12±0.12), CD4 (-0.29±0.24 vs. 0.21±0.30), CD4 CM (-0.23±0.20 vs. 0.36±0.27), CD4NA (-0.33±0.32 vs. 0.31±0.39), and CD8EM (-0.16±0.31 vs. 0.32±0.31). The change in number of CD4CM was higher in MCE compared to CNT (0.36±0.27 vs. -0.24±0.42). No changes were found for IL-7 or RTEs.

CONCLUSION: Immune responses to exercise training in women with an elevated risk of breast cancer are likely to vary depending on the intensity of exercise. Future research should focus on investigating the potential that exercise may have on T-cell phenotypes and their relation to breast cancer risk.

(No relevant relationships reported)

PURPOSE: The gut microbiota regulates metabolic function and energy balance, and an altered microbial ecology contributes to the development of several metabolic diseases including obesity. To examine the association between obesity and the human gut microbiota composition in Japanese children, fecal concentrations of Bacteroidetes, Firmicutes, Actinobacteria, Proteobacteria and Firmicutes/Bacteroidetes ratio were analyzed in 42 young children.

METHODS: The subjects were 42 young children (6 obese, 36 non-obese) aged 4.5-6.5 years. Obesity was determined upon an obesity index score ((real weight - standard weight) / standard weight×100) of more than +15%. To extract enterobacterial DNA, 0.2 g of feces was used to crush cells, centrifuge several times, and collect precipitates to prepare a DNA solution. Next, RNAase treatment was performed on the DNA solution to prepare a PCR solution. Submit the amplified DNA to the next-generation sequencer team of the Faculty of Applied Biological Sciences, Gifu University, and perform metagenomic analysis using the Illumina MiSeq(TM)II system by quantitative RT-PCR targeting bacterial 16S rRNA. It was. The items to be detected were phylum classification, bifidobacteria, lactic acid bacteria, and F/B ratio. **RESULTS:** The fecal concentrations of Bacteroidetes, Firmicutes, Actinobacteria and Proteobacteria in 42 young children were 31.9±9.4%, 58.6±10.5%, 7.0±4.8% and 1.7±1.4%. The obtained data indicate that obese children have a significantly higher level of Firmicutes (Effects size=1.08) and lower level of Bacteroidetes (Effects size=1.13) compared to non-obese children ($p < .05$). The Firmicutes to Bacteroidetes ratio was higher in obese children compared with non-obese subjects ($p < .05$, Effects size=0.74). However, the gut microbiota diversity, bifidobacteria and lactic acid bacteria were not different between the obese and non-obese groups.

CONCLUSIONS: Gut microbial properties differ between obese and non-obese subjects in Japan, suggesting that gut microbiota composition is related to obesity.

Exercise Preconditioning-induced Attenuation Of Acute Colitis Is Associated With Gut Microbiota Symbiosis In Wild Type Mice

Jinkyung Cho, Donghyun Kim, Minjung Kang, Hyunsik Kang.
 Sungkyunkwan University, Suwon, Korea, Republic of.

Email: lovebuffalo@gmail.com

(No relevant relationships reported)

PURPOSE: To investigate the therapeutic effect of exercise preconditioning against acute colitis induced by high-fat diet (HF) plus mild dextran sulfate sodium (DSS) treatment in wild type mice.

METHODS: C57BL/6 male mice aged at 6 weeks were assigned to standard chow (SC, n=10) or HF (n=10) or HF plus DSS (HF+DSS, n=10) or exercise preconditioning (EX) with HF+DSS (EX+HF+DSS, n=10), and the mice were subjected to 15 weeks of dietary treatments, with 12 weeks of a moderate treadmill running (50 minutes per session and 5 days per week) and 2 cycles of 5-day DSS (2% w/v) administration included. Measured parameters included clinical symptoms of acute colitis, pro- and anti-inflammatory and chemotactic cytokines, gut barrier proteins, and immunity cells. Gut microbiota was explored by 16S ribosomal RNA amplification sequencing in fecal samples.

RESULTS: Chronic exposure to HF resulted in colitis symptoms (significant weight gain, enlargement of the spleen, and shortening of colon length) and histological changes in the colon, decreased gut barrier proteins (zonula occludens-1 and heat shock protein 70), infiltration of immunity cells (neutrophils and monocytes in the colon and blood), increased expression of toll-like receptor 4 in the colon, and increased pro-inflammatory and chemotactic cytokines (interleukin-6, growth-regulated oncogene- α , and monocyte chemoattractant protein-1) and decreased anti-inflammatory cytokine (adiponectin) in the colon and blood, and those pathologic

markers of acute colitis were exacerbated by DSS treatment. Exercise preconditioning alleviated the severity of HF+DSS-induced acute colitis and caused symbiotic modifications in gut microbiota, as shown by a lesser abundance of *Bacteroides vulgatus* ($p=0.050$) and a greater abundance of *Akkermansia muciniphila* ($p=0.050$). **CONCLUSIONS:** The current findings suggest that exercise preconditioning alleviates the severity of HF+DSS-induced colitis in conjunction with gut microbiota symbiosis in wild-type mice, implying a preventive/therapeutic potential of promotion of physical fitness via regular exercise against this experimentally-induced acute colitis. This study was supported by the National Research Foundation Grant funded by the Korean Government (NRF-2018R1D1A1B07048153 and 2019R111A1A01052817).

Frequency And Mode Of Physical Activity Influence Gut Microbial Composition In Overweight And Obese Adults

Stephanie M. Wilson, Nicholas V. Pinkham, Sarah E. Bronsky, Seth T. Walk, Carl J. Yeoman, Mary P. Miles, FACSM. *Montana State University, Bozeman, MT.*
 Email: stephanie.keene@montana.edu
 (No relevant relationships reported)

Chronic diseases are linked to adverse phylogenetic and functional alterations in the gut microbiota. Physical activity (PA) regimens may provide a low-cost and practical means to improve "gut health" in individuals at-risk of developing chronic disease. Endurance exercise has been shown to alter gut microbial composition in heavier sedentary individuals but it is not known how other PA modes impact the gut microbiota. It is hypothesized that PA mode and frequency may underlie differences in the gut microbiota in heavier adults.

PURPOSE: To examine the relationship between PA measures and gut microbial richness and evenness and composition in overweight and obese adults. **METHODS:** Adults ($n=38$), 28-55 years old with BMI 27-36 kg·m⁻² were asked about their frequency of aerobic, strength, and stretching exercise during one week. Participants were measured for their age-predicted $\dot{V}O_2$ max using a modified Bruce protocol on a treadmill. DNA was extracted from self-collected fecal samples for Illumina MiSeq amplicon sequencing of 16S rRNA V4. Sequencing reads were processed according to MOTHUR standard operating procedures, with operational taxonomic unit assignment at the 97% similarity threshold. General linear models were used to test effect of PA measures on alpha diversity indices. Distance-based redundancy analyses were used to evaluate community composition in relation to PA measures.

RESULTS: Shannon and Simpson indices did not differ by estimated $\dot{V}O_2$ max nor by PA frequency and mode ($p > 0.05$). Frequency and mode of PA explained more variability in the gut microbial community (11.6%) than estimated $\dot{V}O_2$ max (1.9%). Community patterns were not explained by estimated $\dot{V}O_2$ max ($p = 0.81$). However, PA frequency and mode did explain community patterns with the frequency of strength training during the week showing a greater impact ($p < 0.01$) than aerobic ($p = 0.66$) and stretching exercise ($p = 0.72$).

CONCLUSIONS: PA frequency and mode exhibit greater impacts on the gut microbial community structure than cardiorespiratory fitness in overweight and obese adults. In particular, the incorporation of strength exercise may have a larger impact on the gut microbial community than previously thought. Supported by Montana State University Research Initiative 51040-MUSRI2015-03 and USDA-NIFA 2017-67018-26367.

Exercise Training Restores Age-impaired Nrf2 Signaling And Redox Capacity

Ethan L. Ostrom, Savannah Berry, Ciara Terry, Nadja Jones, Hannah Beskind, Tinna Traustadóttir. *Northern Arizona University, Flagstaff, AZ.*
 Email: elo42@nau.edu
 (No relevant relationships reported)

Purpose Nuclear erythroid-2-p45-related factor 2 (Nrf2) is an inducible transcription factor and the master regulator of antioxidant defenses. We have previously shown that older men have blunted Nrf2 signaling in response to a single exercise stimulus, compared to young. The present RCT tested the hypothesis that moderate exercise training would improve Nrf2 signaling in older, inactive individuals and this would translate to greater redox capacity against non-exercise oxidative stress challenge.

Methods Young (18-28y, $n=21$) and older ($\geq 60y$, $n=24$) men and women were randomized to an 8-week aerobic exercise intervention (EX) or a non-exercise control group (CON). EX performed supervised aerobic exercise 3d/wk for 45-min/d. $\dot{V}O_2$ peak was measured on a cycle ergometer. Nrf2 nuclear localization and GCLC protein were measured in response to acute exercise (30-min cycling at 70% $\dot{V}O_2$ peak) in peripheral blood mononuclear cells at 7 time points (Pre, +10m, +30m, +1h, +4h,

+8h, +24h). Plasma F_2 isoprostanes were measured in response to forearm ischemia-reperfusion (I/R trial) as a marker of redox capacity. All measures were performed pre- and post-intervention

Results EX improved $\dot{V}O_2$ peak by 15%, while CON did not change ($p < 0.001$), with no differences between age-groups or sexes. Nrf2 signaling response to acute exercise increased in EX compared to CON ($p < 0.001$), in both young and older, in support of aerobic exercise restoring Nrf2 signaling in previously inactive individuals. GCLC protein content was increased in EX with no change in CON ($p = 0.03$). Interestingly, CON had higher basal levels of nuclear Nrf2 after the intervention but did not respond to the acute stimulus indicating impaired signaling responses. Redox capacity was improved in EX compared to CON ($p < 0.05$) as shown by lower F_2 -isoP responses to the I/R trial. Furthermore, there was a significant association between improvements in $\dot{V}O_2$ peak and improvements in the I/R response ($r = -0.46$, $p < 0.01$).

Conclusion To our knowledge, this is the first study to show increased Nrf2 activation in healthy humans, in response to an exercise intervention. These data support our hypothesis and demonstrate that older individuals can improve their cell signaling in response to exercise and systemic response to a non-exercise oxidative challenge.

E-08 Thematic Poster - Sleep and Physical Activity: Health and Behavioral Outcomes

Physical Activity And Sleep Quality In Community-dwelling Older Adults

Inaam El-Rajab, Daniel Niederer, Oliver Vogel, Jan Wilke, Lutz Vogt. *Goethe-University Frankfurt, Frankfurt/Main, Germany.*
 (No relevant relationships reported)

Increasing life expectancy has implications for the health system. There is strong evidence that health is dependent on peoples' lifestyle. Sufficient and regular physical activity as well as a good sleep quality are major factors for improved health. Despite health benefits, the majority of older adults do not meet evidence-based physical activity recommendations. Moreover, the prevalence of sleep disorders in this age group is high. **PURPOSE:** To determine the association between physical activity and sleep quality in community-dwelling older adults (>65 years). **METHODS:** This cross-sectional study is based on 64 community-dwelling older adults (82.1 ± 6.4 years (MD ± SD); females 42). Barthel-Index was used for physical disability rating. The average amount of physical activity was assessed by means of accelerometer (MyWellnessKey), measured on 4 out of 7 consecutive days. Self-reported sleep quality, duration and bed rest time were obtained using the Pittsburgh Sleep Quality Index (PSQI). Bivariate correlations (Spearman-Rho) were used to explore relationships between physical activity and sleep quality. In order to analyze differences between subgroups (≥ 7 , 6-7, 5-6, <5 hours of sleep; Barthel Index <90 vs. ≥ 90 pts) univariate ANOVAs were applied; in case of significance followed by Tukey-HSD post-hoc analyses. **RESULTS:** Physical activity levels among community-dwelling older adults ranged from 561.2 to 5335.7 moves per week. No linear association between physical activity and sleep quality was found ($p > .05$). In subgroup analyses ($n = 41$, Barthel Index ≥ 90 pts, free of pre-existing conditions) physical activity levels (2251.6 ± 1119.1, 2516.4 ± 644.5, 3528.7 ± 1461.9, 2019.2 ± 1105.2 moves per week) differed significantly ($p = .037$) between groups of different sleep duration. The association between physical activity and sleep quality was confined to older adults reporting ≥ 7 hours of sleep and older adults reporting 5-6 hours of sleep ($p = .049$). **CONCLUSION:** Present data indicate comparable low to very low physical activity levels in community-dwelling older adults. There is no accordance between higher activity levels and better sleep quality in the investigated cohort per se. However, a sleep duration of 5-6 hours seems to be associated with 7.6 hours bed rest time and a higher level of physical activity.

Associations Of Sleep, Physical Activity, And Sedentary Behavior Across Pregnancy TrimestersKara M. Whitaker¹, Christopher E. Kline², Janet Catov², Bethany Barone Gibbs². ¹University of Iowa, Iowa City, IA. ²University of Pittsburgh, Pittsburgh, PA.

Email: kara-whitaker@uiowa.edu

(No relevant relationships reported)

PURPOSE: Sleep and physical activity are altered in pregnancy and may affect pregnancy health; however, whether these behaviors influence each other is not well understood. In this study, we describe self-reported sleep parameters across pregnancy trimesters and examine associations with objectively measured moderate-to-vigorous physical activity (MVPA) and sedentary behavior (SB). **METHODS:** Women were recruited from Iowa City, IA and Pittsburgh, PA to assess sleep, MVPA, and SB in each trimester of pregnancy. Sleep was measured using the Pittsburgh Sleep Quality Index. MVPA and SB were estimated using a waist-worn ActiGraph GT3X and thigh-worn activPAL3 micro, respectively; data were considered valid with ≥ 4 days of ≥ 10 hours of wear. Mixed effects models were used to examine changes in sleep parameters (global sleep score, poor sleep quality, sleep efficiency, sleep duration) across trimesters. Associations of MVPA and SB trajectories with sleep parameters were also examined using mixed effects models. **RESULTS:** Women (n=120) averaged 31.1 ± 4.7 years of age with a pre-pregnancy BMI of 26.8 ± 6.7 kg/m². As seen in the Table, differences were found for all sleep parameters across pregnancy trimesters, with adverse changes occurring in the third trimester compared to the first and second trimesters. MVPA trajectory was not associated with any of the sleep parameters. Women in the high SB trajectory had greater sleep efficiency ($\beta=4.78\%$, 95% CI: 0.07, 9.49) and women in the moderate and high SB trajectories also had longer sleep duration ($\beta=0.79$ hours, 95% CI: 0.23, 1.35; $\beta=0.80$ hours, 95% CI: 0.26, 1.33, respectively), compared to those in the low SB trajectory. **CONCLUSIONS:** Few studies have examined self-reported sleep measures across pregnancy trimesters. Findings indicate that sleep quality, efficiency, and duration are adversely affected in the third trimester. Contrary to our hypotheses, high SB but not MVPA was favorably associated with sleep parameters.

Table: Sleep across pregnancy trimesters and associations of moderate-to-vigorous intensity physical activity (MVPA) and sedentary behavior (SB) trajectories with sleep

Trimester	PSQI Global Sleep Score*	Poor Sleep Quality ^b	Sleep Efficiency %	Sleep Duration Hours
	Mean \pm SD	n(%)	Mean \pm SD	Mean \pm SD
First (n=120)	6.1 \pm 3.0	58 (48.7)	83.9 \pm 13.4	7.1 \pm 1.4
Second (n=116)	6.0 \pm 3.3	56 (49.6)	85.0 \pm 12.4	7.1 \pm 1.5
Third (n=114)	7.3 \pm 3.4	75 (66.4)	80.8 \pm 12.6	6.5 \pm 1.2
p-value	<0.001	0.006	0.006	<0.001
Trajectories ^c	β (95% CI)	OR (95% CI)	β (95% CI)	β (95% CI)
MVPA				
Low (n=35)	0.65 (-0.70, 2.00)	-0.62 (-1.51, 0.27)	-0.54 (-5.47, 4.39)	-0.40 (-0.97, 0.17)
Medium (n=59)	-0.08 (-1.32, 1.15)	-0.17 (-1.00, 0.63)	-0.10 (-4.41, 4.60)	-0.36 (-0.89, 0.16)

Physical Activity And Sleep Quality Differ In LGBTQ Compared To Non-LGBTQ College Students

Ginny M. Frederick, Isaura M. Castillo-Hernandez, Ewan R. Williams, Anneliese A. Singh, Ellen M. Evans, FACSM. University of Georgia, Athens, GA. (Sponsor: Ellen M. Evans, FACSM)

Email: vmf04863@uga.edu

(No relevant relationships reported)

PURPOSE: Disparities in health outcomes exist for members of the lesbian, gay, bisexual, transgender, and queer (LGBTQ) community across the lifespan. Regarding sleep quality (SQ) specifically, obtaining adequate restorative sleep is a challenge for many individuals, especially college students. Although it is well established that habitual physical activity (PA) is associated with improved SQ in many cohorts, the relationship between PA and SQ among LGBTQ college students remains unstudied. This study aimed to compare PA and SQ, and their associations, in LGBTQ and non-LGBTQ college students. **METHODS:** Self-identified LGBTQ (n = 84; 20.6 ± 2.2 yo) and non-LGBTQ college students (n = 456; 20.8 ± 2.0 yo) completed online surveys: a) Pittsburgh Sleep Quality Index (PSQI) and b) International Physical Activity Questionnaire (IPAQ)

with subsequent MET-min/wk and days of resistance training (RT) being calculated. T-tests were used to compare SQ and PA levels of LGBTQ and non-LGBTQ students. Bivariate correlations explored relationships between SQ and PA within groups. **RESULTS:** LGBTQ students reported less aerobic PA (2226.1 ± 1478.9 vs. 2641.9 ± 1643.5 MET-min/wk) and less frequent RT (1.3 vs 1.9 days/wk) than non-LGBTQ students (all p \leq 0.05). Global PSQI scores indicated poor SQ for both LGBTQ and non-LGBTQ students (6.85 and 5.79, respectively); however, LGBTQ students reported 16.7% higher scores indicating poorer SQ (p \leq 0.05). Among LGBTQ students, higher aerobic PA was associated with improved SQ (r = -0.24, p \leq 0.05) whereas no association was observed in non-LGBTQ students (r = -0.05, p = 0.25). No associations between RT and SQ were observed in either group (both p \geq 0.05). **CONCLUSIONS:** Disparities exist between LGBTQ and non-LGBTQ college students regarding self-reported PA and SQ. Although causality cannot be determined, our findings suggest that increasing PA could improve SQ, particularly among LGBTQ college students. Future research should explore the utility of PA to enhance SQ using more robust methodologies toward the end of informing effective health promotion programming.

2467 Board #4 May 29 9:30 AM - 11:30 AM

The Combined Associations Of Physical Activity And Sleep With Depressive Symptoms In Women With Young Children.

Marquis S. Hawkins, Daniel J. Buyssee, Kaleab Z. Abebe, Judy C. Chang, Kathleen M. Mctigue, Michele D. Levine, Esa M. Davis. University of Pittsburgh, Pittsburgh, PA. (Sponsor: Andrea Kriska, FACSM)

Email: mah400@pitt.edu

(No relevant relationships reported)

PURPOSE: To examine the combined associations of PA and sleep with depressive symptoms in women with young children. **METHODS:** We analyzed data from the National Health and Nutrition Examination Survey (2007-2014). We included women with children < 5 years of age, not pregnant, with complete data on physical activity, sleep, and depressive symptoms (n=1,222). The primary exposures were self-reported physical activity (some vs. none) and sleep duration (> 6 vs. < 6 hours/night). The primary outcome was moderate-to-severe depression (referred to as "depression" going forward). Multivariable logistic regression was used to compare odds of depression by engagement in PA and sleep individually or in combination. No PA and short sleep duration (< 6 hours/night) was the reference group. **RESULTS:** Participants had a mean age of 31.2 yrs and their youngest child had a mean age of 2.33 yrs. Approximately 48%, 82%, and 40% performed some PA, slept > 6 hours/night, and both respectively. Depression was prevalent in 10% of the sample. Engaging in some PA and sleeping > 6 hours/night were associated with an unadjusted 0.41 (95% CI 0.26 to 0.64) and 0.40 (95% CI 0.25 to 0.64) odds of depression. The combined associations of engaging in some PA and sleeping > 6 hours/night were more strongly associated with depression (OR = 0.16, 95% CI 0.09 to 0.29) than either behavior alone. This relationship persisted after adjustment for education, race/ethnicity, marital status, obesity, poverty status, and the child's age (OR = 0.19, 95% CI 0.10 to 0.38). **CONCLUSIONS:** PA and sleep, considered separately and in combination, were associated with fewer depressive symptoms in women with young children. The combination of adequate PA and sleep may have greater mental health benefits than either behavior alone. Future studies should examine the effects of promoting PA and sleep on postpartum depression in women.

Impact Of Increased Sleep Duration On Physical Activity And Mood In Adolescents

Andrea M. Spaeth, Emily E. Glavin. Rutgers, The State University of New Jersey, New Brunswick, NJ. (Sponsor: Sara Campbell, FACSM)

Email: ams853@kines.rutgers.edu

(No relevant relationships reported)

PURPOSE: The majority of adolescents are chronically sleep deprived and exhibit low levels of physical activity. Greater physical activity has been associated with improved sleep in teens; however, the effect of a sleep extension intervention on physical activity has not been assessed. The purpose of this study is to determine if increasing a high-school student's sleep opportunity to 10h per night for one week leads to greater physical activity and improvements in mood. **METHODS:** Ten high school students (14-17y) exhibiting habitual short sleep (< 7.5 h/night) were enrolled in the study. During orientation and follow-up visits, participants completed the Profile of Mood States. For one week between orientation and follow-up visits, participants were prescribed a bedtime and wake time, provided with time management and sleep hygiene strategies, and received payment contingent upon adherence to the assigned sleep schedule. During this week, sleep and physical activity were measured daily using the Phillips Respironics Actiwatch Spectrum Plus worn on

the wrist 24h per day and Actigraph GT3x worn on the hip during waking hours for at least 8h a day, respectively. Data were analyzed using repeated-measures ANOVA (SPSS 26.0).

RESULTS: Eight participants completed the study (50% female). Prior to the sleep intervention, participants self-reported sleeping 420.6 min (7.0h) per night. During the intervention, participants increased sleep duration to 502.8 min (8.4h) per night. Mood was significantly improved (total mood disturbance: $p=0.01$, confusion: $p=0.04$, fatigue-inertia: $p=0.01$, vigor-activity: $p=0.03$). Time spent in sedentary and light physical activity did not significantly change during the intervention; however there was a non-significant ($p=0.16$) increase in the proportion of time spent in moderate-to-vigorous activity from the first-2 days (6.5%) to the last-2 days (8.5%) of the intervention. When asked if they perceived any changes in physical activity, the majority of participants ($n=7$) reported that they became less sedentary because they did not have time to engage in sedentary activities (e.g., watching television).

CONCLUSIONS: Increasing sleep duration is a promising approach to increasing physical activity and improving the physical and mental health of adolescents.

Poor Sleep Quality Increases Sedentary Time In A College Student Cohort

Trent A. Hargens, FACSM, Matthew C. Scott, Valerie C. Olijar, Matthew B. Bigman, Elizabeth S. Edwards, FACSM. *James Madison University, Harrisonburg, VA.*

Email: hargenta@jmu.edu

(No relevant relationships reported)

Quality sleep is essential for health and quality of life, and can impact academic performance. Prior research has shown a reduced sleep time in college students. A relationship has been shown between sleep quality and physical activity (PA), but has not been examined extensively in a college cohort, nor has sedentary behavior been factored in.

PURPOSE: To examine the effect of sleep quality on sedentary and PA behavior in college students. **METHODS:** Eighty-one female ($n = 53$) and male ($n = 28$) college students (age = 20.2 ± 1.5 yr; BMI = 25.1 ± 4.7 ; % body fat = 31.8 ± 10.2) underwent 7-day objective PA and sleep assessment via ActiGraph accelerometer. Poor sleep quality was defined as total sleep time (TST) < 6 hours or sleep efficiency (SE; TST / Total time in bed) $< 85\%$. One-way ANOVA was utilized to assess mean differences in PA and sedentary behavior between poor sleep (PS) and normal sleep (NS). **RESULTS:** Based on weekly averages, 22 subjects had poor sleep quality by TST criteria, and 43 subjects had poor sleep quality by SE criteria. Based on TST, PS resulted in greater number of sedentary bouts per day (20.6 ± 2.8) vs. NS (18.5 ± 3.8 , $P = 0.02$), fewer minutes per sedentary break per day (45.2 ± 9.1 and 53.5 ± 14.5 , for PS and NS, respectively, $P = 0.02$), and greater average sedentary minutes per day (701.4 ± 79.4 and 645.1 ± 106.6 for PS and NS, respectively, $P = 0.03$). Average moderate-to-vigorous PA minutes (MVPA) did not differ between PS (65.0 ± 30.0) and NS (57.6 ± 23.9 , $P = 0.25$), nor did any other PA variable. Based on SE, the PS (65.3 ± 27.2) had greater MVPA minutes compared to NS (53.2 ± 22.7 , $P = 0.04$). No other PA variable differed. There was no difference in body composition between groups when analyzing by TST or SE criteria. **CONCLUSION:** Poor sleep quality, defined as less than 6 hours of TST, appears to have a greater impact on sedentary behavior than PA behavior in a college student population. When sleep quality is poor, college students experience a greater amount of sedentary behavior, while PA variables did not change. This may be a result of the college lifestyle, where walking on campus to classes and other PA is needed regardless of daytime sleepiness as a result of poor sleep. This is one of the first studies to show a relationship between sleep quality and sedentary time in a college-age population.

Lifestyle Characteristics As Predictors Of Adolescent Sleep Duration: Evidence From A National Survey

Christopher D. Pfledderer, Qingqing Hu, Rachel L. McCarty, Ryan D. Burns. *University of Utah, Salt Lake City, UT.*

Email: chris.pfledderer@utah.edu

(No relevant relationships reported)

Chronic sleep deprivation is frequent among adolescents with only about a quarter of high school students in the United States reporting getting the 8 to 10 hours of sleep per night that is recommended for their age group. While some behaviors associated with adolescent sleep duration have been established, most studies have only examined a small subset of risk factors and have not utilized a nationally representative sample of adolescents.

PURPOSE: The purpose of this study was to examine patterns of adolescent sleep from a large sample of high school students throughout the U.S using data from the 2017 National Youth Risk Behavior Survey (YRBS) and to identify lifestyle factors that associate with meeting sleep recommendations.

METHODS: A multi-stage cluster sampling procedure was employed to yield a representative sample of US adolescents recruited from the 9th through 12th

grade. The number of sampled adolescents was 18,324 with 7,640 students submitting questionnaires with usable data for this study. Backward selection and weighted logistic regression models were employed to examine the predictive utility of independent health behaviors associating with adolescents meeting sleep recommendations, adjusting for age and BMI percentile. The final model included physical activity, alcohol use, and screen time as salient predictors of sleep duration. **RESULTS:** A total of 1,948 (25.5%) adolescents reported sleeping 8 hours or more per night. Meeting physical activity guidelines (OR = 1.18, 95% CI: 1.02-1.38, $p = 0.03$) associated with higher odds of meeting sleep recommendations. Using a computer more than two hours per day (OR = 0.62, 95% CI: 0.54 - 0.71, $p < 0.01$) and consuming alcohol (OR = 0.66, 95% CI: 0.54 - 0.71, $p < 0.01$) independently associated with lower odds of meeting sleep recommendations. These associations held after controlling for age and BMI percentile.

CONCLUSION: The majority of adolescents in the United States do not meet current sleep recommendations for their age group and multiple health behaviors associate with the odds of meeting these recommendations. Programs that aim to promote sleep hygiene among adolescents should focus on multiple lifestyle behaviors in an effort to improve sleep duration among youth.

Relationship Between The 24-hour Movement Guidelines And Fundamental Motor Skills In Preschoolers

Chelsea L. Kracht¹, E. Kipling Webster², Amanda E. Staiano¹.
¹Pennington Biomedical Research Center, Baton Rouge, LA.

²Augusta University, Augusta, GA.

Email: chelsea.kracht@pbrcc.edu

(No relevant relationships reported)

The 24-hour movement guidelines recognize the collective influence of child physical activity (PA), sleep, and screen-time on development. An important part of child development is fundamental motor skills (FMS), as higher FMS competency in preschool is related to greater PA in adolescence. It is unknown whether meeting preschool movement guidelines are associated with FMS. **PURPOSE:** To examine the association among 24-hour movement guidelines and FMS in preschoolers. **METHODS:** Children ages 3-4 years of age were recruited from childcare centers. Parents reported child age, sex, race, and time spent viewing screens (hours/day). Child PA and sleep were measured using accelerometry. The 24-hour movement guidelines were examined (≤ 1 hour/day of screen-time, ≥ 3 hours/day total PA of which ≥ 1 hour/day is moderate-to-vigorous, and 10-13 hours/day of sleep). To measure FMS, trained researchers administered the Test of Gross Motor Development - Third Edition (TGMD-3). Raw score of the two subscales (Locomotor and Ball skills) and total TGMD-3 score were used for analysis. Linear regression was used to assess individual and number of guidelines met with total, locomotor, and ball skill scores. Crude models and models adjusting for age, sex, and race were conducted. **RESULTS:** Of the 112 participants, 86 provided complete measures (76%). Preschoolers were 3.4 ± 0.5 years old, 53% were male, 52% were White, and the sample was below average in the age-and-sex adjusted total score percentile (41 ± 21). Most children met the PA guideline (94%) and sleep guideline (87%), but few met the ST guideline (12%) or all three guidelines (10%). In crude models, those who met the PA guideline had a higher total ($p=0.04$) and ball skills scores ($p=0.01$), and those who met the ST guideline had a lower ball skills score ($p=0.04$). However, these associations were not significant in adjusted models ($p>0.05$). No other relationships between individual or number of guidelines and FMS scores were found. **CONCLUSIONS:** In this sample, there was no relationship between movement guidelines and FMS when adjusting for other factors. Promotion of adequate movement behaviors and FMS is still warranted for later child health.

(No relevant relationships reported)

BACKGROUND: How field-test results are associated with match-related physical performance is understudied, especially in elite youth soccer players. **PURPOSE:** To investigate relationship between field-test outcome and physical performance during official soccer matches in elite youth soccer players. **METHODS:** During pre-season, elite youth soccer players (n = 27; age = 17.1±0.9 years; height = 177.9±7.4 cm; weight = 71.0±5.5 kg) performed field tests including running acceleration on 5 m (AC5) and 10 m (AC10), maximal speed running (MSR), Agility 505 with turning on dominant (A505D) and non-dominant leg (A505N), and Yo-Yo test level 1 (Yo-Yo). Following the field-test, the same players wore GPS devices (GPSports Canberra, Australia) in 12 official soccer matches. The GPS can measure total distance covered (TDC), distance covered in different speed zones (Z1-Z6), high-metabolic load distance (HMLD), maximum speed (MS), acceleration (ACC) and deceleration (DCC) in different effort zones (EZ1-EZ3). Pearson correlation analysis and canonical correlation were used to find an association, and paired sampled test was employed to compare 1st and 2nd half differences. **RESULTS:** Results revealed significant, moderate correlation between AC5 and ACCEZ3 in 2nd half (r=.450, p=.02), AC10 vs ACCEZ1 in 1st, 2nd half and full match (r=.453, r=.390, r=.444), S10 vs ACCEZ2 in 1st half (r=.382, p=.049), AC10 vs ACCEZ3 in 2nd half (r=.543, p=.003). Yo-Yo test outcome was strongly correlated with TDC in match (r=.871, p=.000) and TDC in both halves (1st: r=.871, p=.000, 2nd: r=.723, p=.000). Significant correlation was found between Yo-Yo and HMLD (r=.758, p=.000) and HMLD for both halves (1st: r=.695, p=.000, 2nd: r=.707, p=.000). Canonical correlation (R_c) between field test variables and match performing was .940 (R_c²=.884). The highest canonical loading were: TDC (-.971), HMLD (-.818), YoYo (-.972). The highest cross loadings variables were: TDC (-.913), HMLD (-.769), and YoYo (-.914). **CONCLUSIONS:** Our study identified several pre-season field tests that were associated with match-related physical performance. An intermittent exercise capacity was the strongest predictor for physical match performance in youth elite soccer players. Supported by GACR19-12150S, UNCE HUM32

(No relevant relationships reported)

The impact of match congestion, training load (TL), perceived stress, fatigue and soreness on the odds of injury remains unclear. **PURPOSE:** To examine the influence of: 1) days rest between matches on injury rate (IR) and odds of injury and; 2) TL on injury, perceived stress, fatigue and soreness. **METHODS:** A prospective multi-site study tracked daily exposures, TL (distance and duration), injury and perceptual data from six Division I NCAA women's soccer teams in one season. Overall and non-contact (NC) IRs expressed per 1000 athlete exposures (AEs), and odds ratios (OR) were determined by days before and after matches. Associations between injury and changes in both TL and perception were analyzed using a multilevel logistic regression. **RESULTS:** 139 players experienced 94 injuries in 137 matches and 107 injuries in 363 practices. Overall match and practice IRs (per 1000AEs [95%CI]) were 39.0 [31.1, 46.9] and 17.1 [13.9, 20.3], respectively. While insignificant (p > 0.21), match IRs were highest 2 days between matches (IR= 50.9 [26.7, 75.1]). Players were at increased odds of being injured in a match with 1 to 5 days since the last match vs. 6+ days (OR [95%CI] = 1.79 [1.02, 3.17]). Practice IRs were highest in the pre-season (IR = 28.8 [17.0, 40.5]). Players were at increased odds of sustaining a NC overuse injury with 1-5 days between matches vs. 6+ days (OR=7.85 (1.06, 57.94); p=0.04). Similarly, 1-3 days' rest had 2.24 (1.03, 4.88) times higher rates on NC overuse IR than 4+ days' rest (p=0.05). Acute NC IR was increased with 1 to 3 days rest vs. 4+ days rest (OR= 3.01 [1.11, 8.14]; p=0.03). Players were at increased odds (p < 0.001) of feeling fatigue (> 5) (OR= 4.71 [1.82, 12.17]) and soreness (> 5) (OR= 7.68 (2.67, 22.10)) on match day with 2 days vs. 7+ days since the last match. For each additional 3000m covered on a day, odds of overall injury, soreness and fatigue increased (41%, 32% and 31% respectively). **CONCLUSION:** Days between matches and acute TL increases on a given day had a negative impact on odds of injury and perception. The odds of getting injured in a match were greater with 1 to 5 days vs. 6+ days between matches. These data may be used to inform and guide the NCAA in determining optimal scheduling and recovery.

Biomarkers Differ Between And Within Starters And Non-Starters Throughout A Collegiate Soccer Season

Cody R. Butler¹, Robert A. Huggins¹, Adam S. Lepley², Ryan M. Curtis¹, Courtney L. Benjamin¹, Yasuki Sekiguchi¹, Douglas J. Casa, FACSM¹. ¹University of Connecticut, Mansfield, CT. ²University of Michigan, Ann Arbor, MI. (Sponsor: Douglas J. Casa, FACSM)
Email: cody.butler@uconn.edu
(No relevant relationships reported)

PURPOSE: To observe differences in blood biomarkers (oxygen (O₂) transport, immune, cardiovascular (CV) health and hematology) between starters (S) and non-starters (NS) over a full NCAA Division I collegiate men's soccer season. **METHODS:** Biomarkers (n = 30) related to O₂ transport (n = 9), immune function (n = 12), and CV and lipid profiles (n = 9) were collected at the start of pre-season (PS), in-season at weeks (W)1, 4, 8 and 12 in soccer players (n = 20, mean ± SD; age = 21 ± 1, height = 180 ± 6 cm, body mass = 78.19 ± 6.3 kg, body fat = 12.0 ± 2.6%, VO_{2max} = 51.5 ± 5.1 ml·kg⁻¹·min⁻¹). A 2 x 5 (group x time) repeated measures ANOVA was used to identify differences between S (n = 10) and NS (n = 10). In the presence of a significant interaction effect (p<0.05), post-hoc one-way ANOVAs and paired tests were used to identify group and time differences with uncorrected alpha level set at p<0.05. **RESULTS:** A significant interaction effect (group x time) was found for 9 biomarkers (hematocrit [HCT], hemoglobin [HGB], red blood cells [RBC], total cholesterol [Total Chol], LDL cholesterol [LDL], Chol:HDL ratio, non-HDL cholesterol [non-HDL], direct LDL [dLDL] and apolipoprotein B [ApoB]). S demonstrated significant increases in RBC (W1) and Chol:HDL (W8), while NS demonstrated significant increases in HCT and HGB (W4); Chol:HDL (W4, 12). Within-group significant

differences were found between PS and W1 for NS (HCT, HGB, RBC, Total Chol, LDL, Chol:HD, Non-HDL, ApoB) and for S (Chol:HDL, non-HDL, dLDL). HCT, HGB, RBC, LDL, Non-HDL, Direct LDL and Apo B were different in NS from W1 to W4, while only Apo B was different in S. From PS to W12, Total Chol, LDL, and non-HDL were significantly different for NS while HCT, HGB, Chol:HDL, and non-HDL were different in S.

CONCLUSIONS: Our findings indicate that there are differences between and within S and NS for many biomarkers related to O₂ transport, immune, CV health and hematology throughout a collegiate men's soccer season. Thus, future analyses should account for playing status as a covariate. From a clinical perspective, while all biomarkers were within normal reference ranges, sports medicine personnel should account for playing status and inter-individual differences when tracking or diagnosing athletes who demonstrate signs of clinical pathologies associated with these biomarkers.

Variability Of Heart Rates During Small Sided Games In Female College Soccer Players

Scott Richmond, Vinay Patel. *Lindenwood University, St. Charles, MO.*

Email: SRichmond@Lindenwood.edu
 (No relevant relationships reported)

Soccer is one of the most popular sports in the world that include small sided games (SSGs) as a match specific type of training. Much is known about the physiological demands of official match-play (OM), however less is known about which practice elements most closely mimic OM situations. **PURPOSE:** To assess differences in HR and soccer performance during SSGs in female college soccer players in comparison to a full competitive match. **METHODS:** Twenty female collegiate soccer players (mean \pm SD; age = 20 \pm 1 yrs, height = 169 \pm 6cm, weight = 64 \pm 6kg) were recruited to participate in this study. A commercially available team monitoring system was used to measure HR and determine time spent in various zones based on %HRmax. Player touches (contacting the ball) were based on video analysis of each session. Field size (120m x 75m) for the SSGs were kept constant, but the intensity of the games were influenced by the number of players involved (6 vs 6, 7 vs 7, 8 vs 8, 9 vs 9 and 11 vs 11). **RESULTS:** A one-way repeated measures ANOVA showed there was a significant main effect of average HR on SSGs, $F(4, 64) = 11.248$; $p < 0.01$. The average %HRmax responses increased in concert with the increased number of players in SSGs (6 vs 6 = 73 \pm 6%, 7 vs 7 = 75 \pm 10%, 8 vs 8 = 81 \pm 7%, 9 vs 9 = 83 \pm 5%, and 11 vs 11 = 83 \pm 6%). A one-way repeated measures ANOVA showed there was a statistically significant main effect of group size on the number of touches, $F(4, 64) = 12.67$, $p < 0.001$. The number of touches were inversely related to the number of players (11 vs 11 = 46 \pm 16, 9 vs 9 = 61 \pm 15, 8 vs 8 = 66 \pm 22, 7 vs 7 = 78 \pm 22, and 6 vs 6 = 86 \pm 28). A two-way Mixed Model ANOVA showed there was no significant main effect of position (DEF, MID, STK) on time spent in heart rate zones, $F(2, 72) = 1.38$, $p > 0.05$. **CONCLUSION:** Changes in SSGs game format affect the players. Using SSGs can allow coaches to more closely alter physiological and technical demands differently. The greater touches with fewer players may enhance technical ability. However, fewer players in SSGs are also associated with a lower %HRmax. The 9 vs 9 SSGs formats provide players with the opportunity to spend sufficient proportion of time spent in high intensity HR zones that are specific to OM.

Relationship Between Sleep Quantity And Quality And Performance Variables In Female Collegiate Soccer Players.

Beau K. Greer¹, Marisa R. Abegg², Michael J. Ormsbee, FACSM², Lynn Panton, FACSM². ¹*Sacred Heart University, Fairfield, CT.* ²*Florida State University, Tallahassee, FL.*
 (Sponsor: Lynn Panton, FACSM)
 Email: greerb@sacredheart.edu
 (No relevant relationships reported)

Support for sport-specific benefits of sleep quantity and quality are limited, particularly in female collegiate athletes. **PURPOSE:** To evaluate the relationship between sleep quantity and quality and soccer-specific performance variables in an elite group of female soccer players. **METHODS:** Eight NCAA college-aged competitive Division I women's soccer players (18-23 yrs) participated in the study. Global Positioning Systems (GPS), heart rate monitoring, and video analysis technologies were used during four matches along with 24-hour actigraphy; actigraphy was also used to measure sleep quantity and quality. The night prior to the match was used for data analyses of sleep quantity and quality. A multivariate analysis of variance (MANOVA) was utilized to determine whether the vectors of the means in groups of variables were significant. Paired t-tests were used to analyze if differences in variables of performance existed after the "best" and "worst" nights of sleep for quantity and quality. Significance was set at $p < 0.05$. **RESULTS:** Mean sleep quantity and quality for the "best" (575.0 \pm 38.4 minutes, 91.9 \pm 2.6% of time in bed spent sleeping) and

"worst" (416 \pm 57.6 minutes, 76.2 \pm 12.1% of time in bed spent sleeping) nights were significantly different. The MANOVAs were not significantly different for the physiological and physical variables for quantity and quality of sleep. No differences in performance variables were observed after "best" and "worst" quantity sleep matches. However, percent time spent exercising above 85% of the maximal heart rate (HRmax) was significantly lower after the "best" quality night of sleep (30.2 \pm 13.5 vs. 47.9 \pm 24.3%), even though overall heart rate exertion was higher after the "best" night of sleep (518.5 \pm 193.1 vs. 387.6 \pm 148.9 AU). High metabolic load distance (distance running at speeds greater than 19 km/hr) and distance accelerating or decelerating quickly (>2 m/s²) was lower (11.8 \pm 3.6 vs. 16.3 \pm 6.0 yds/min) and the number of decelerations was higher after the "best" quality night (69.7 \pm 28.1 vs. 50.6 \pm 25.9). **CONCLUSION:** While quantity of sleep did not influence performance related outcomes, quality of sleep may be important for reducing the time spent exercising $>$ 85% HRmax and reducing incidence of high orthopedic stresses.

Pre-season Hip/groin Strength Is Associated With Subsequent Injury In Professional Male Soccer Players

Matthew Noel Bourne¹, Morgan Williams², Ryan Timmins³, Tania Pizzari⁴. ¹*Griffith University, Gold Coast, Australia.* ²*University of South Wales, Cardiff, United Kingdom.* ³*Australian Catholic University, Melbourne, Australia.* ⁴*La Trobe University, Melbourne, Australia.*

(No relevant relationships reported)

PURPOSE:

Hip and groin injuries are a significant cause of time lost from training and competition in elite soccer (football). The aim of this study was to explore the association between pre-season assessments of 1) isometric hip adductor and abductor strength using a novel field-test; and 2) the Copenhagen Hip and Groin Outcome Score (HAGOS), and subsequent hip/groin injury in professional male football players. **METHODS:** In total, n=204 elite male football players from ten professional Hyundai A-League and English Championship League clubs underwent assessments of hip adductor and abductor strength and completed the HAGOS in the 2017-18 pre-season. In-season hip/groin injuries were reported by team medical staff. Data reduction was conducted using principal component analysis. The principal component for HAGOS and three principal components for strength and imbalance measures were entered with age and prior hip/groin injury into a multivariable logistic regression model to determine their association with prospectively occurring hip/groin injury. **RESULTS:** Twenty-four players suffered at least one hip/groin injury throughout the 2017-18 competitive season. The principal component for between-limb abduction imbalance (peak strength in the preferred [kicking] limb - non-preferred limb) (OR = 0.58, 95% CI = 0.38 to 0.90, $p = 0.011$), the principal component for peak adduction and abduction strength (OR = 0.71, 95% CI = 0.50 to 1.00, $p = 0.045$), and the principal component for HAGOS (OR = 0.77, 95% CI = 0.62 to 0.96, $p = 0.022$), were independently associated with a reduced risk of future hip/groin injury. Receiver operator curve analysis of the whole model revealed an area under the curve of 0.76, which indicates a fair combined sensitivity and specificity of the included variables but an inability to correctly identify all subsequently injured players. **CONCLUSIONS:** In this cohort, a hip abduction imbalance favouring the preferred kicking limb, higher levels of hip adductor and abductor strength, and better HAGOS values, were all associated with a reduced likelihood of future hip/groin injury.

2479 Board #7 May 29 9:30 AM - 11:30 AM
Peripheral Perception In Soccer: Effects Of Sports-specific Dual Task Training

Nils Schumacher, Mike Schmidt, Rüdiger Reer, Klaus-Michael Braumann. *University of Hamburg, Hamburg, Germany.*
 Email: nils.schumacher@uni-hamburg.de

(No relevant relationships reported)

In soccer, abilities such as peripheral perception seem to be of special importance. However, the extent to which these skills can be improved through practical and sports-specific training interventions has not been conclusively clarified. **PURPOSE:** To examine the effect of an 8-week sports-specific training intervention under dual-task conditions on the peripheral perception of young, highly talented soccer players. **METHODS:** 34 highly talented male soccer players (12.7 \pm .5 yrs) were assigned to an intervention group (IG: 15 subjects) and a control group (CG: 19 subjects). Computer-based measurements were conducted for pretest (T0) and posttest (T1). Outcome parameters were reaction time (RT) for left-sided (RTL) and right-sided (RTR) peripherally perceived stimuli. The sports-specific perceptual cognitive training (8 weeks, 20 min weekly) consisted of juggling training and two soccer-specific double tasks ("juggling and peripheral passing", "foveal focus and peripheral reaction"). **RESULTS:** The two-way ANOVA showed a significant interaction effect for RTR between the groups (IG, KG) and the measurement times (T0, T1) ($F(1, 32) = 9.63$, $p = .004$, $\eta^2 = .23$). For left-sided stimuli (RTL) ANOVA did not show a significant interaction effect (time x group) ($F(1, 32) = .49$, $p = .49$, $\eta^2 = .02$). A significant

interaction effect (time x group) could be determined for RT ($F(1,32) = 4.85, p = .035, \eta^2 = .13$). **CONCLUSIONS:** The intervention showed a significant effect on right-sided peripheral reaction time of highly talented soccer players. The analysis of the left-sided reaction time showed no significant interaction effect. Based on demands for sports-specific transfer tasks, the shown training intervention represents a practical approach to improve perceptual-cognitive skills. In future analyzes, neurophysiological parameters (e.g. changes in activity in the motor cortex) should be recorded in order to determine the importance of dual tasks for the development of perceptual-cognitive abilities of young highly talented soccer players and to understand underlying mechanisms.

2480 Board #8 May 29 9:30 AM - 11:30 AM
The Accuracy Of Female Collegiate Soccer Players In Self-Detecting Ventilatory Threshold During Maximal Exercise Testing

Stacey L. Buser, Nicole Krueger, Judith Juvancic-Heltzel, Ronald Otterstetter, FACSM. *The University of Akron, Akron, OH.*

(No relevant relationships reported)

INTRODUCTION: Ventilatory threshold (VT) is the point at which minute ventilation (V_E) increases nonlinearly with increasing exercise intensity. Several previous studies have shown that subjects are able to recognize their VT by noticing changes in their breathing during exercise bouts. High importance can be placed on knowing VT, as positive training adaptations for sport occur when the intensity is at or above this threshold. There are no previous studies examining team sport athletes detecting VT. **PURPOSE:** Determine whether female collegiate soccer players can accurately perceive the changes in ventilation associated with their VT during maximal exercise testing. **METHODS:** Volunteers were recruited from a women's collegiate soccer team ($n=17$, age = 19 ± 1.56 yrs.) to participate in the study. All subjects performed a modified maximal treadmill protocol with breath-by-breath gas analysis throughout the test. All subjects were given instructions from a script asking them to indicate when they noticed a significant change in their breathing, and this was recorded as their perceived ventilatory threshold (PVT). Actual VT was recorded and calculated from the maximal exercise test results. Pearson product correlation and independent samples t-tests were used to test the relationships and mean differences between oxygen consumption (VO_2), ventilatory frequency (VF), minute ventilation (V_E), and tidal volume (V_T) at PVT and VT. Significance was set at $p < 0.05$. **RESULTS:** Data was collected for 13 subjects. Positive correlations were found between actual VT and PVT on physiological variables with TV having a very strong relationship ($r=.932$), VO_2 a strong relationship ($r=.714$), and VF ($r=.684$) and VE ($r=.49$) with moderate relationships. On average, subjects perceived their VT after surpassing their actual VT. There were no statistically significant differences for mean difference on average between VO_2 , $\%VO_{2max}$, VF, V_E , and V_T at PVT versus VT. **CONCLUSION:** In respect to the current study, female collegiate soccer players may be able to detect the changes in their breathing associated with VT, which could be useful in prescribing exercise for this population. Coaching professionals could use PVT as a reliable mark for players to train above their VT to produce desired training effects.

Sagittal And Frontal Plane Joint Moments Of The Sumo Deadlift During Shod And Barefoot Conditions

Kevin A. Valenzuela¹, Kellie Walters¹, Alexis Camacho¹, Fany Alvarado¹, Elizabeth Avila¹, Joshua A. Cotter, FACSM¹, Hunter J. Bennett². ¹California State University Long Beach, Long Beach, CA. ²Old Dominion University, Norfolk, VA. (Sponsor: Joshua Cotter, FACSM)

Email: kevin.valenzuela@csulb.edu

(No relevant relationships reported)

Sumo style deadlifting has recently become more prevalent. Barefoot-style lifting has also become increasingly popular with claims such as increased force production and improved "grounding" of the foot. However, the biomechanics of sumo deadlifting while barefoot have not been examined. **PURPOSE:** To examine the effects on the hip, knee, and ankle joint moments during a sumo deadlift when comparing shod and barefoot conditions. **METHODS:** Ten subjects (27.3 ± 3.5 yrs, 1.74 ± 0.13 m, 77.97 ± 17.34 kg) with minimum six months of deadlift experience (7.6 ± 4.6 yrs), who were free from lower extremity injury, performed 1 repetition maximum (1RM; 137.7 ± 43.0 kg) testing on day 1. This testing was performed in self-selected footwear. On day 2, a minimum of 72 hours later, subjects lifted 70% of their 1RM during a 3-dimensional analysis. Subjects performed one set of five continuous repetitions of a sumo deadlift in shod and barefoot conditions in randomized order. Five minutes of rest was given between sets. Marker data were collected using Qualisys Track Manager, sampling at 240Hz. Force data were collected using Bertec force plates, sampling at 1200Hz. Raw marker and force data were imported into Visual3D. Marker and force data were filtered using a fourth-order lowpass Butterworth filter at 8Hz. Peak internal sagittal and frontal plane joint moments of the hip, knee, and ankle were calculated during the concentric phase of each repetition. Peak vertical ground reaction force was measured during the concentric phase. **RESULTS:** No significant differences were detected in peak hip extension moment ($p=0.855$), hip abduction ($p=0.288$), knee extension ($p=0.607$), knee abduction ($p=0.926$), ankle plantarflexion ($p=0.376$), ankle eversion ($p=0.739$), or peak vertical ground reaction force ($p=0.558$). **CONCLUSIONS:** There is no evidence to suggest that the barefoot lifting style increases performance capabilities when lifting the same weight as in the shod condition. Additionally, there is no evidence to suggest that there is any increased risk in excess frontal plane joint moments during barefoot lifting. Future research should examine the 1RM capabilities in both shod and barefoot conditions to determine if differences exist during maximal compared to submaximal efforts.

Email: fany.alvarado@student.csulb.edu

(No relevant relationships reported)

Electromyography of the Quadriceps and Hamstrings During the Conventional Deadlift in Two Shoe Conditions

Fany Alvarado¹, Kellie Walters¹, Elizabeth Avila¹, Alexis Camacho¹, Joshua A. Cotter (FACSM)¹, Hunter J. Bennett², & Kevin A. Valenzuela¹

¹California State University Long Beach, Long Beach, CA

²Old Dominion University, Norfolk, VA

Introduction: The conventional deadlift is a widely used strength exercise and barefoot lifting has become a more prominent style of training. Currently there is a lack of research comparing electromyography (EMG) activity between shoe and barefoot styles of training. The purpose of the study was to compare the difference in vastus medialis and biceps femoris muscle activity during the concentric phase of the conventional deadlift. **Methods:** Seven subjects with a mean weight 80.3 ± 17.4 (kg) and height 1.8 ± 0.1 (m) participated in the study with at least six continuous months of deadlifting experience, 1-2 days/week of strength training, no surgeries and no

lower back/lower extremity injuries within the past six months. Day one consisted of 1RM testing based on NSCA guidelines. On day two subjects were fitted with two EMG sensors (biceps femoris, vastus medialis) and a maximal voluntary isometric contraction was performed. The subjects then completed two sets of five randomized repetitions (with shoes and barefoot) at 70% of their 1RM. Raw data were imported to visual 3D. EMG data were bandpass filtered (20Hz-450Hz), full-wave rectified, linear enveloped, and smoothed using a moving RMS (window size of 25 frames). A paired-samples t-test ($p < 0.05$) was used to compare muscle activity of the biceps femoris and vastus medialis. **Results:** The percentage of vastus medialis recruitment was significantly greater ($p = 0.005$) in the shoe ($53.5 \pm 26.9\%$) vs. barefoot condition ($46.7 \pm 24.1\%$). Additionally, there was a significant difference in percentage of biceps femoris recruitment ($p = 0.037$) between the shoe ($43.8 \pm 25.0\%$) condition and barefoot ($45.2 \pm 33.1\%$) condition. **Conclusion:** Using a barefoot approach in the conventional deadlift appears to have an effect on percent peak muscle activation of the biceps femoris and vastus medialis muscles. Early evidence may suggest that barefoot lifting styles increase hamstring activation while decreasing quadriceps activation.

2484 Board #3 May 29 9:30 AM - 11:30 AM
The Effects Of Fatigue On Lumbo-Pelvic Coordination During The Deadlift

Vanessa Ramirez, Alex Spencer, Michael Samaan, Babak Bazrgari. *University of Kentucky, Lexington, KY.*
 Email: vjra222@uky.edu
 (No relevant relationships reported)

Repetitive lifting with submaximal loads has gained popularity as a mean for increasing strength and endurance. Given that repetitive lifting is a known occupational risk factor for low back injury, it is important to develop an objective criterion for determination of number of lifting repetitions that maximize the benefits of lifting, while minimizing the potential risk for low back injuries. **Purpose:** To determine whether measures of lumbo-pelvic coordination (LPC) during repetitive low-handle hexagonal bar deadlift (LHBD) get impaired before lifter exhaustion. **Methods:** Eight weight-trained males performed repetitions-to-fatigue of LHBD with a load of 68 kg. Rotations of the thorax and pelvis in the sagittal plane, measured using a motion capture system, were used to characterize LPC according to Needham, et al. 2015. Subsequently, the differences in LPC over the early portion of the lifting phase between the first and last 10% of total lifting repetitions were compared using paired to-tests. **Results:** Peak pelvic and trunk flexion angles and lumbar range of rotation from respective values of $53.9^\circ \pm 4.8^\circ$, $64.9^\circ \pm 6.6^\circ$, and $28.8^\circ \pm 3.2^\circ$ during the first 10% of lifting cycles increased to $57.2^\circ \pm 4.1^\circ$ ($p = 0.02$) $69.4^\circ \pm 6.7^\circ$ ($p = 0.05$), and $32.9^\circ \pm 5.2^\circ$ ($p = 0.04$) during the last 10%. Pelvic and trunk rotations over the early portion of the lifting phase were in-phase (anti-phase) $40.0\% \pm 8.8\%$ ($21.3\% \pm 2.8\%$) of the time during the first 10% of lifting cycles that increased, $p = 0.04$, (decreased, $p = 0.01$) to $47.9\% \pm 4.8\%$ ($12.4\% \pm 4.9\%$) during the last 10% of lifting cycles. **Conclusion:** Significant changes in neuromuscular control of LPC were observed before participants stop lifting due to fatigue. Such alterations in LPC changes mechanical loads experienced in the spinal tissues, hence, affecting risk of injury. However, more research is needed to understand the impact of such impairments in LPC on spinal loads and risk of injury.

 (No relevant relationships reported)

Deadlifts are often an integral part of training programs to build posterior chain strength and power, but current research has not examined the performance outcomes when performed with and without shoes from a biomechanical perspective. **PURPOSE:** To examine the differences in lower extremity sagittal plane joint kinetics and peak vertical ground reaction force (vGRF) of a conventional barbell deadlift with and without shoes. **METHODS:** Ten subjects (age: 27.9 ± 3.8 years) who deadlift twice a week for the past 6 months, were free from injury, and had no history of lower extremity surgery were recruited. Subjects first performed a one repetition max (1RM) test in self-selected footwear according to NSCA guidelines. At least 72 hours later subjects returned for a 3-dimensional analysis of their deadlift at 70% of their 1RM. Subjects performed 1 set of 5 continuous reps of a conventional deadlift in both shoe and barefoot conditions in a randomized order. A 5-minute rest was given between each condition. Visual3D was used to process raw marker and force data, calculate peak sagittal joint moments of the ankle, knee, and hip and to find peak vertical ground reaction force during the concentric phase. A one-way repeated measures MANOVA

was performed to statistically test differences between shoe and no shoe conditions in the dependent variables. **RESULTS:** Average 1RM for males and females was 437.5 ± 83.4 lbs. and 224.2 ± 37.6 lbs., respectively. No significant differences were found in internal hip extension moments ($p = 0.444$, $S = 2.99$ Nm/kg, $B = 3.05$ Nm/kg), knee extension moments ($p = 0.151$, $S = 0.92$ Nm/kg, $B = 0.81$ Nm/kg), ankle plantar flexion moments ($p = 0.113$, $S = 1.07$ Nm/kg, $B = 1.01$ Nm/kg), and peak vGRF ($p = 0.295$, $S = 1044.9$ N, $B = 1035.2$ N) between shoe and barefoot conditions. **CONCLUSION:** Anecdotal claims suggest performing a deadlift barefoot enhances stability and increases connection to the ground which would lead to improvement in deadlift performance. The lack of difference seen in sagittal plane kinetics and peak vGRF suggest that deadlift performance is unaffected by footwear choice. Future research should investigate if similar results would be attained when subjects' deadlift performance is tested at various percentages of the 1RM.

The Influence Of Normalization Technique On Between-muscle Activation During A Back-squat: Methodological Considerations

Adam Korak¹, Brett D. Bruininks¹, Max R. Paquette². ¹University of St. Thomas, St. Paul, MN. ²University of Memphis, Memphis, TN.
 Email: adam.korak@stthomas.edu
 (No relevant relationships reported)

Abstract

Background/Objective: Currently, no gold standard electromyography (EMG) normalizing technique exists when conducting between-muscle comparisons of muscle activity during isotonic resistance training exercises. The aim of this study was to assess if between-muscle activation during the back-squat differed among electromyography (EMG) normalization techniques when normalizing to: (1) 1 repetition maximum (1RM), (2) maximal voluntary isometric contraction (MVIC), and (3) the first of a set of three repetitions (Rep1%) in trained female lifters. **Methods:** Thirteen participants completed a back-squat 1RM, MVIC of the rectus-femoris (RF) and gluteus-maximus (GM), and three repetitions of the back-squat at 80% 1RM. For the 1RM and MVIC normalization techniques, the average of the peak RMS signal of both muscles during the three submaximal reps were normalized to the peak 1RM and MVIC signals. The Rep1% averaged the peak RMS signals of both muscles during the 2nd and 3rd submaximal repetitions normalized to the peak signal during the 1st repetition. **Results:** The RF-GM between-muscle EMG (Δ EMG) differed among normalization techniques ($p < 0.001$, $\eta_p^2 = 0.48$). **Post-hoc** pairwise comparisons indicated MVIC normalization elicited different Δ EMG with large effects compared to both 1RM ($p = 0.037$; $d = 1.2$) and Rep1% ($p = 0.004$; $d = 1.9$) techniques, but the 1RM and Rep1% did not produce different Δ EMG ($p = 0.27$; $d = 0.8$). **Conclusion:** Our findings suggest EMG normalization technique influences the magnitude and direction of between-muscle activation during common lifting exercises, and we recommend normalizing isotonic movements to dynamic normalization methods such as a 1RM or Rep1%.

Impact Of Vibration On Rectus Femoris During Track Athletes Bodyweight Squats In Female Collegiate Track Athletes

Maggie J. McDermott, Moroni A. de Moors, Samuel J. Arter, Andy M. Bosak, Jessi J. Glauser, Samantha L. Yamasaki, James E. Schoffstall, FACSM. *Liberty University, Lynchburg, VA.*
 (Sponsor: James E. Schoffstall, FACSM)
 (No relevant relationships reported)

Whole-body vibration (WBV) exposes the entire body to mechanical oscillations when one is standing on a vibrating platform. In recent years, researchers have studied the extent to which these oscillations effect the body. Previous studies have investigated muscle activity in the general population during static exercises with WBV, but there has been little research that has focused on the effects of WBV during dynamic movements in athletes. **PURPOSE:** The purpose of the study was to investigate the effects of WBV on rectus femoris muscle activity during a whole-body squat (WBS) exercise in NCAA Division 1 female track and field athletes. **METHODS:** Fifteen NCAA Division 1 track and field female athletes (Height = 165.20 ± 7.85 cm; Weight = 61.11 ± 9.46 kg; BF% = 18.80 ± 4.92 %; Age = 19.80 ± 1.57 years) were assessed for adequate squat form using the FMS deep squat protocol. Subjects then completed a dynamic warm-up before a wired EMG sensor was placed over the rectus femoris muscle belly of the right leg. Subjects completed two trials consisting of 10 repetitions of WBS with and without WBV, in a counterbalanced order. Root mean squared (RMS) values were collected using the EMG sensor during WBS trials. RMS values for WBS during each trial were analyzed using a Dependent t-Test with an alpha level of $p \leq 0.05$. **RESULTS:** Mean values for RMS were 74.92 ± 22.81 μ V for WBV trials, and 53.11 ± 24.46 μ V for ground squat trials. The values for RMS were significantly

($p < 0.001$) greater for the WBV trials. **CONCLUSIONS:** Significantly higher RMS values occurred for the WBV trials which may indicate that more motor units were recruited in the rectus femoris when the athlete was performing WBS and experiencing WBV. Future research may be required to determine if the current study's results may apply to collegiate male track and field athletes.

2488 Board #7 May 29 9:30 AM - 11:30 AM
Muscle Excitation During Single Leg Rotational Squat In Individuals With And Without Previous Hamstrings Injury

Jessica A. Mutchler¹, Claudia Simpson¹, Joshua T. Weinhandl², Matthew C. Hoch³, Samuel J. Wilson¹, Bonnie L. Van Lunen⁴.
¹Georgia Southern University, Statesboro, GA. ²University of Tennessee, Knoxville, TN. ³University of Kentucky, Lexington, KY. ⁴Old Dominion University, Norfolk, VA. (Sponsor: Tamerah Hunt, FACSM)
 Email: jmutchler@georgiasouthern.edu
 (No relevant relationships reported)

PURPOSE: To compare lower extremity muscle excitation patterns between individuals with and without a previous hamstrings injury when performing a single leg rotational squat (SLRS). **METHODS:** Eight recreationally active individuals with a history of hamstrings injury within 5 years (4 males, 4 females; age=21.25±1.58 years; height=1.76±0.07m; mass=78.21±12.96kg; Hamstring Outcome Score=88.28±7.5%), were matched to 8 individuals with no history of hamstrings injury (4 males, 4 females; age=22.12±1.55 years; height=1.76±0.08m; mass=76.29±13.62kg; Hamstring Outcome Score=97.19±2.81%). Wireless EMG surface electrodes were placed bilaterally on the rectus femoris, vastus medialis oblique, biceps femoris, medial hamstrings, and gluteus medius. EMG data was sampled at 2000Hz. Participants completed five trials of a SLRS moving to four counts of a 72bpm metronome. Four phases were defined: 1) down phase from standing to squat, 2) rotating towards maximum excursion marker, 3) rotating away from maximum excursion back to straight-ahead squat, and 4) standing up from squat. EMG signals were passed through a 4th order, zero lag, Butterworth high-pass filter with cut-off at 10Hz, low-pass filter with cut-off at 350Hz, and full wave rectified. Mean EMG of each muscle during each phase was normalized to the maximum EMG of the entire task, and analyzed as %EMG. Between group differences were assessed using separate one-way ANOVAs for each muscle and phase. Alpha level was set at $p < 0.05$. **RESULTS:** %EMG of the medial hamstrings during phase two was significantly higher in the healthy group as compared to the hamstring group (Healthy: 8.66 ± 2.83%, Hamstring: 5.943 ± 1.74%; $p = 0.037$, effect size = 1.15). No other significant differences were observed ($P > 0.05$). **CONCLUSION:** Muscle excitation patterns of the rectus femoris, vastus medialis oblique, biceps femoris, and gluteus medius of individuals with a previous hamstrings injury appear similar to those with no history of hamstrings injury when performing a SLRS. Differences in excitation of the medial hamstrings during the rotation to maximum excursion could indicate a difference in movement strategy between the groups when performing the phase that requires the highest demand of dynamic stability.

Effect Of Unilateral Anterior Knee Pain On 3d Net Support Moments During Split Squats

Anna C. Severin. University of Arkansas for Medical Sciences, Little Rock, AR.
 Email: aseverin@uams.edu
 (No relevant relationships reported)

Anterior knee pain (AKP) is common in the active population.¹ and biomechanical differences exist between individuals with and without AKP.² Individuals with AKP portray changes in coordination,³ kinematics, and muscle function^{1,2} though, the 3D net joint moment (NJM) and relative joint contributions (RJC) of the lower extremity joints during squat tasks is not well-documented. **PURPOSE:** Quantify differences in NJM and RJC during split squats between individuals with and without AKP. **METHODS:** Data from 15 active young adults with unilateral nonspecific AKP (≥ 3 months), and 15 controls (C) was collected with a 9-camera motion capture system (500 Hz) and two force platforms (2000Hz). Ten continuous split-squats were performed with each leg leading (AKP: injured and non-injured). The hip, knee, and ankle moments of the lead and trail legs were extracted at the bottom of the movement. NJM was calculated as described by Paterson⁴. Paired statistics were used for between-leg differences and between-group analyses were performed using an ANCOVA, with the squat depth as a covariate. The alpha level was 0.05 and Cohen's D indicated effect size. **RESULTS:** No difference existed in squat depth. No differences existed between limbs in the C group so the data were pooled.

There was less NJM in the injured limb and more in the non-injured limb when the injured limb was leading compared to controls (Figure 1). When in the trail position, the injured limb produced less NJM than the uninjured. The RJC from the lead hip was lower for the AKP, while their contribution from the knee was higher. **CONCLUSION:** The total NJM suggested an increased reliance of the non-injured leg during split-squats, which likely offloads the injured leg. The RJC from the lead hip was less in the injured group (C: 50%, AKP: 46/44%), while the knee was higher (C: 30%, AKP: 34/38%). This was unexpected and highlights demands for further research.

Influence Of Injury Severity And Recovery Environment On Physical Activity And Function Following Lower-limb Amputation

Peter Ladlow¹, Thomas E. Nightingale², M. Polly McGuigan³, Alexander N. Bennett¹, James L. J. Bilzon³. ¹UK Ministry of Defence, Loughborough, United Kingdom. ²University of British Columbia, Vancouver, BC, Canada. ³University of Bath, Bath, United Kingdom. (Sponsor: Professor James Betts, FACSM)
 Email: Peter.Ladlow100@mod.gov.uk
 (No relevant relationships reported)

Restoration of physical function and physical activity (PA) is considered a vital therapeutic component in the short-term rehabilitation and long-term recovery of individuals with traumatic lower-limb amputation(s) (LLA). Unfortunately, evidence suggests an increased prevalence of physical inactivity and reduced functional status in this population. **PURPOSE:** To determine the impact of free-living environment (rehabilitation vs. home) on PA and function in UK military personnel following

traumatic LLA, compared to active non-injured controls (CON). **METHODS:** Sixteen LLA (8 unilateral (UNI), 30±5yrs; 8 bilateral (BI), 29±3yrs), nearing the end of their clinical rehabilitation care pathway, attended one 4-week residential rehabilitation admission and one 6-week recovery block at home. Thirteen physically active, age-matched males (28±5yrs) represented CON. Estimated daily ambulatory PA energy expenditure (PAEE) was estimated from an accelerometer (Actigraph GT3X+), worn on the hip of the shortest residual limb in each environment, using validated population specific prediction algorithms. Six minute walk distance (6MWD) was recorded at baseline and 10 weeks (general population 6MWD norms is >459m). **RESULTS:** Whilst at home, mean PA counts.day⁻¹ reduced by 17% (p=0.018) and 42% (p=0.001) in the UNI and BI group, respectively. UNI group demonstrated a similar capacity for PAEE to CON, both of which were greater (P<0.05) than BI (Table 1). No significant changes in 6MWD were demonstrated within groups (P>0.05), however, significant differences (P<0.05) were demonstrated between all groups at baseline (UNI, 574±66m; BI, 337±85m, CON, 705±32m). **CONCLUSION:** UNI group demonstrate a similar capacity for PA and function to active non-injured CON. To support and manage the long-term health and well-being of more severely injured BI LLA, future research should investigate strategies that promote regular engagement in PAEE, particularly when they return home.

Estimated daily physical activity in all groups. Data presented as mean±SD and Δ mean

Cross-sectional Evaluation Of Musculoskeletal Outcomes & Physical Activity Levels In Patients With Aggrecan Deficiency

Paul J. Gubanich, FACSM¹, Eirene Alexandrou¹, Hee Kim¹, Leah Tyzinski¹, Vivian Hwa¹, Andrew Dauber², Philippe Backeljauw¹. ¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH. ²Children's National Health System, Washington DC, DC.
 Email: paul.gubanich@cchmc.org
 Reported Relationships: **P.J. Gubanich:** Industry contracted research; Novo Nordisk.

PURPOSE: Aggrecan is a key proteoglycan found in the extracellular matrix of articular and physal cartilage and provides resistance to compression and deformity. Aggrecan deficiency is a recently described autosomal dominantly inherited condition due to mutations in the *ACAN* gene. Individuals with aggrecan deficiency experience premature growth cessation, short stature, and advanced skeletal maturation. Proteoglycan loss has been associated with osteoarthritis and degenerative joint disease. This study examines the joint manifestations of a cohort of prepubertal patients and affected family members with Aggrecan deficiency. **METHODS:** Proband (ACAN mutation, bone age ≥ chronological age, normal IGF-I) and affected relatives underwent baseline joint evaluation including history and physical exam, quality of life, physical activity (Marx), joint specific outcomes (Pedi-IKDC, Oswestry), and radiographic assessment (knee x-ray and MRI). **RESULTS:** Twenty subjects (9 male, 11 female, ages 2.4-62.6 years) were enrolled in the study. The average Pedi-IKDC of the pediatric subjects (mean age 6.5+/-3.2 years, range 2.4-12.5 years) was 95.5+/-8.9 compared to 74.9+/-20.1 for adult subjects (mean age 42.9+/-10.6 years, range 25.4-62.6 years), (p=0.02). The average Marx activity score was 12.2+/-2.2 for pediatric subjects compared to 2.6+/-4.4 for the adults (p<0.001). Two pediatric subjects reported a history of knee pain while none reported back or other musculoskeletal concerns. Additionally, two pediatric subjects were identified with osteochondral defects on MRI while 2 others displayed variant MRI findings. Of the 9 adults, 67% reported knee pain (4 patellar dislocations), 88% displayed osteoarthritis on knee x-ray, 67% reported other joint concerns, and 56% reported back pain. Seven orthopedic surgeries were reported. **CONCLUSIONS:** Patients with ACAN deficiency appear to be at high risk of premature joint complications as evidenced by (1) the high rate of knee, back, and joint complaints, (2) increased requirement for surgical intervention, and (3) low physical activity scores. Early surveillance of joint

complaints, lifestyle counseling and therapeutic interventions to improve joint health and maintain physical activity should be considered to optimize patient outcomes and quality of life.

Reduced Muscle Sympathetic Nerve Activity Response To A Cold Pressor Test In Multiple Sclerosis

Claire E. Trotter¹, Mu Huang², David M. Keller³, Scott L. Davis¹. ¹Southern Methodist University, Dallas, TX. ²University of Texas Southwestern Medical Center, Dallas, TX. ³University of Texas at Arlington, Arlington, TX.
 Email: cetrottr@smu.edu
 (No relevant relationships reported)

Multiple sclerosis (MS) is a neurodegenerative autoimmune disease characterized by demyelination in central nervous system leading to potential impairments in the autonomic control of cardiovascular function. We have previously demonstrated individuals with MS exhibit a diminished ability to increase blood pressure in response to a hypotensive stimulus compared with healthy controls likely due to impaired sympathetic modulation of the vasculature. **Purpose:** The aim of the current investigation was to test the hypothesis that muscle sympathetic nerve activity (MSNA) responses to a cold pressor test (CPT) are reduced in individuals with MS compared to healthy controls. **Methods:** Four patients with relapsing-remitting MS (2 females/2 males, EDSS < 4) and 4 sex-, age- and mass-matched controls were instrumented for MSNA (peroneal nerve), mean arterial blood pressure (MAP; Finometer), and heart rate (HR). Subjects were exposed to a CPT by immersing a hand in ice water for 2 min. Mean cardiovascular and MSNA responses (burst frequency) at baseline and at 30 sec intervals during the CPT were compared between groups. **Results:** Heart rate (P<0.001) and MAP (P<0.001) responses increased from baseline throughout the CPT but no group differences were observed (P=0.10 and P=0.78, respectively). At baseline, MSNA was similar between groups (MS: 2 ± 2 vs. CON: 14 ± 9 bursts/min; P=0.239). However, individuals with MS had blunted MSNA responses to CPT compared to healthy controls at 60 seconds (MS: 18 ± 14 vs. CON: 42 ± 10 bursts/min; P=0.033), at 90 seconds (MS: 16 ± 12 vs. CON: 44 ± 10 bursts/min; P=.017) and 120 seconds (MS: 13 ± 12 vs. CON: 43 ± 13 bursts/min; P=.012). **Conclusion:** Individuals with MS appear to have an attenuated muscle sympathetic response to CPT. However, MAP appears to respond similarly to healthy controls potentially through other compensatory mechanisms.

The Adoption Of Spinal Cord Injury Policies In The Secondary School Setting

Samantha E. Scarneo¹, Lindsay J. DiStefano¹, Johna K. Register-Mihalik², Benjamin A. Saltzman¹, Emma E. Kryzanski¹, Douglas J. Casa, FACSM¹, Erik E. Swartz³. ¹University of Connecticut, Storrs, CT. ²University of North Carolina, Chapel Hill, Chapel Hill, NC. ³University of Massachusetts, Lowell, Lowell, MA.
 (Sponsor: Douglas J. Casa, FACSM)
 Email: samantha.scarneo@uconn.edu
 (No relevant relationships reported)

Development of written policies and procedures (P&P) may enhance adequate preparation and management of spinal cord injuries (SCI). **PURPOSE:** To evaluate the current adoption of SCI P&P in the secondary school setting as reported by athletic trainers (ATs). **METHODS:** Using a cross-sectional design, ATs employed in a secondary school (n=3315) were emailed invitations to participate in an online questionnaire about sport safety best practices, which included three questions related to SCI P&P (Table 1). The questions were framed using the Precaution-Adoption Process Model (PAPM), which is a health behavior model aimed at identifying an individual's readiness to act with answers including unaware, unengaged, undecided, decided not to act, decided to act, acting and to maintaining a SCI P&P. Additional questions related to the management of SCI were also asked. Frequencies were tabulated and prevalence ratios with 95% confidence intervals (CI) are presented. **RESULTS:** Of the 389 ATs who responded (response rate = 8.5%) (male= 52.1%, age=41±10 years), a majority reported "maintaining" for all questions (Q1 (Comprehensive SCI plan)= 82.8%, Q2 (Equipment Removal)=79.1%, Q3 (Healthcare professional practice)=64.8%, Table 1). The proportion of ATs reporting being "unaware" was higher in Q2 compared to Q1 (7.2% vs 4.8%; (PR=1.78, 95% CI= 1.11, 2.87)). Further, the ATs reporting "acting" or "maintaining" in Q2 was higher than Q3 (80.6% vs 65.8%; PR=1.22, 95% CI=1.12, 1.33). Approximately half (56.6%) reported they coordinate SCI policy with emergency medical services (EMS). A majority reported they do not document practicing equipment removal (62.2%). **CONCLUSION:** Overall, the PAPM appears to be able to classify ATs readiness to act for the adoption of a SCI P&P, though there was a low proportion in many of the stages. Interventions may be needed to improve the practicing and documentation of equipment removal skills along with collaborative efforts between ATs and EMS.

Question <i>My school has policies and procedures...</i>	Un-aware we needed this	Un-aware if we have	Un-engaged	Un-decided	Decided not to act	Decided to Act	Acting	Maintaining
Q1. Comprehensive plans for immediate care of a potential severe head or cervical spine injury are in place (n=389)	6 (1.5)	13 (3.3)	11 (2.8)	14 (3.6)	10 (2.6)	8 (2.1)	5 (1.3)	322 (82.8)
Q2. Emergency equipment to remove face mask, helmet, and shoulder pads are onsite and in working order (n=387)	14 (3.6)	14 (3.6)	14 (3.6)	11 (2.8)	12 (3.1)	10 (2.6)	6 (1.6)	306 (79.1)
Q3. Policies are in place for healthcare professionals to practice and maintain equipment removal skills regularly (n=384)	25 (6.5)	15 (3.9)	26 (6.8)	21 (5.5)	23 (6.0)	21 (5.5)	4 (1.0)	249 (64.8)

Injury Incidence In Competitive Wheelchair Tennis Athletes

Andrew Heideman¹, Michael A. Yorio¹, Rafael E. Bahamonde, FACSM². ¹Jacksonville Orthopaedic Institute, Jacksonville, FL. ²Indiana University - Purdue University Indianapolis, Indianapolis, IN.

Email: aheideman@joi.net

(No relevant relationships reported)

There is great interest in tennis sports science and in the wheelchair tennis community on the overall injury incidence in competitive wheelchair tennis players. There are biomechanical differences between the wheelchair tennis and the able-bodied tennis serve that have been published. In addition, wheelchair tennis players are required to propel their wheelchair around the court during match play, which exposes the upper extremities and trunk to additional movements during tennis play. Currently, there is a paucity of data published on the injury incidence in competitive wheelchair tennis athletes. **PURPOSE:** To provide a prospective evaluation of the injury incidence in wheelchair tennis players during their competitive schedule. **METHODS:** The study is a prospective cohort study of competitive wheelchair tennis players during their seasons. 81 subjects were enrolled at 5 different tennis tournaments over a two year period. Subjects completed an injury history and a training log at the beginning of the study. 39 subjects volunteered for a physical exam at the start of the study. Once enrolled in the study, the subjects were monitored for injuries through weekly email communication. **RESULTS:** The injury incidence is calculated to be 1.88 injuries per 100 athletic exposures. Of the reported injuries, 2 occurred during match play, 3 occurred during training, and 8 were reported while not playing tennis. There were no statistically significant findings associating physical exam findings and future injury. **CONCLUSIONS:** An injury incidence in competitive wheelchair tennis athletes obtained while competing and training prospectively contributes to the body of evidence to guide further research to evaluate the mechanism of injuries and develop injury risk reduction strategies in a unique population of high performance athletes. Future injury risk reduction strategies should include a focus on potential causes of non-tennis related injuries in competitive wheelchair tennis players.

2496 May 29 10:45 AM - 11:00 AM

Longitudinal Changes In Sensorimotor And Mobility Function In People With Progressive Multiple Sclerosis

Jules D. Miehm¹, Sumire Sato¹, John Buonaccorsi¹, Caitlin Rajala¹, Jongil Lim², Farnaz Khalighinejad³, Carolina Ionete³, Jane A. Kent, FACSM¹, Richard E.A. van Emmerik¹. ¹University of Massachusetts, Amherst, MA. ²Texas A&M, San Antonio, TX. ³University of Massachusetts Memorial Medical Center, Worcester, MA.

Email: jmiehm@umass.edu

(No relevant relationships reported)

PURPOSE: To determine whether changes in sensorimotor function and mobility are apparent between people with relapsing-remitting (RRMS) and progressive multiple sclerosis (PMS) after 1 year of baseline testing. **METHODS:** The percent change relative to baseline (i.e., % change = (visit 2 - visit 1)/visit 1*100), for measures of sensorimotor function and mobility was calculated for 25 RRMS (22

women, 53.2±10.3 yrs) and 26 PMS (16 women, 60.3±8.7 yrs). Sensorimotor function measures included lower-extremity cutaneous vibration sensitivity, proprioception, and central motor drive. Mobility measures included the 25-Foot Walk Test at preferred and brisk speeds (25FWTpref, 25FWTbrisk), and the Timed-Up-And-Go (TUG). One-sample t-tests and pairwise comparisons were used to determine whether within- and between-group performance changed, respectively, relative to baseline. **RESULTS:** One-sample t-tests revealed that RRMS became less sensitive to vibration at the hallux (p=0.014, [5.4, 43.9]), improved 25FWTbrisk performance (p=0.018, [-17.5, -1.8]), and tended to improve performance during the 25FWTpref (p=0.076, [-13.8, 0.7]) and TUG (p=0.053 [-14.8, 0.1]). Results for PMS demonstrated moderately decreased sensation to vibration at all but 1 site on the foot (Hallux: p=0.066, [-1.7, 49.8], Heel: p=0.084, [-2.9, 43.4]) and worsened performance for the 25FWTpref (p=0.090, [-1.4, 17.6]). Neither RRMS nor PMS demonstrated changes in lower-extremity proprioception or central motor drive measures for either one-sample t-tests or pairwise comparisons. Pairwise comparisons between the groups showed a larger % change (improved performance) from baseline to visit 2 in RRMS compared to PMS for all mobility tests (25FWTpref: p=0.015, [-26.2, -3.0], 25FWTbrisk: p=0.009, [-24.3, -3.7], TUG: p=0.048, [-26.5, -0.1]). **CONCLUSION:** Relative to RRMS, people with progressive forms of MS may increase the amount of time it takes to complete the 25FWT. Increased mobility impairment in PMS over a one year period may be explained by decreased sensation, especially related to cutaneous sensitivity at the plantar surface of the foot, which could impact perception of body orientation and foot-ground contact during the stance phase of gait, and thereby impair mobility performance by walking more cautiously at slower speeds.

(No relevant relationships reported)

73 military personnel competed at the 2018 Invictus Games in Sydney, Australia as part of Team UK. The medical support team consisted of two doctors, two nurses and two physiotherapists. **PURPOSE:** To describe the epidemiology of injury and illness of Team UK competitors at the 2018 Invictus Games and the medical demand on the multidisciplinary team (MDT) by role (doctor, nurse & physiotherapist). **METHODS:** Electronic medical notes of the 56 males and 27 females (mean age: 37.18 S.D. 7.67) Team UK athletes were recorded via PPS software platform (Rushcliff, UK 2018). All medical interactions were retrospectively analysed using Excel (Microsoft, USA 2019) by: presenting complaint, MDT role, time, venue, anatomical region, treatment and outcomes. **RESULTS:** Team UK comprised of 60 veterans and 13 serving military personnel. Self-declaration of baseline illness/impairment returned 8 spinal cord injuries, 23 limb deficiencies, 23 musculoskeletal, 6 traumatic brain injuries, 14 neurological and 23 psychological illnesses. In total 198 interactions occurred over the 14 days: 69 doctor interactions, 21 nursing interactions and 108 physiotherapist interactions. Of these 107 were new interactions and 91 follow-ups/re-presentations. Of new interactions 59 (55.1%) were musculoskeletal in origin, 15 (14.0%) were illness, 14 (13.1%) were wound care, 3 (2.8%) were emergency care, 1 (0.8%) was psychological support and 15 (14.0%) were classified as other. The most common anatomical regions were shoulder, lumbar spine and cervical spine. Three acute emergencies required hospital admission: a suspected spinal cord injury, a suspected stroke and a respiratory arrest. 7 interactions led to visits to the local medical centre and three resulted in a quarantine. The highest incidence of interactions occurred within the 6 day competition period: 123 (62.2%) vs. 75 (37.9%) on the 8 days pre/post-competition. The highest incidences by day were the second, the first and last day of competition. 82 (41.4%) interactions occurred outside of competition venues (e.g. transport/hotel). Only 13 (17.8%) athletes had no medical interactions. **CONCLUSION:** These results can be used to inform injury prevention programmes and the composition of future MDTs. The data presented will allow for comparative data to be collected at future Invictus Games.

(No relevant relationships reported)

Dementia has become a critical health problem with negative impacts on the quality of life. It is widely accepted that exercise has beneficial effects on both physical and mental performance of the elderly people.

PURPOSE: This study examined the effect of an exercise training program on physical and mental abilities of nursing home patients in early and middle stages of dementia.

METHODS: Thirty eight patients with early to middle dementia (31 females and 7 males, age: 80.8±6.9 yrs, body mass: 67.84±6.93 kg, height: 164±7 cm) volunteered to participate in the study. They were randomly assigned to either the intervention group (IG), which received a 50-min structured exercise program 3 days/week, or the control group (CG), which followed the usual care, for an experimental period of 9 months. The study was conducted in an elderly care unit, and functional and cognitive parameters were evaluated in both groups before and after the completion of the intervention period.

RESULTS: Compared to pre exercise values, significant improvements ($p < 0.05$) were found in Time Up and Go test (TUG: 15.1±4.6 vs 12.7±4.4 sec), Berg Balance Scale score (BBS: 42.9±3.8 vs 46.3±5.2), Chair-Stand test (CST: 9.5±1.6 vs 18.06±3.8 reps) and Geriatric Depression Scale (GDS: 5.8±2.9 vs 3.8±3.2) in IG, while no change (TUG: 16.8±4.5 vs 18.6±5.9 sec; BBS: 49.1±5.4 vs 40.7±11.1; GDS: 2.9±2.4 vs 6.2±3.6) or deterioration (CST: 14.2±3.1 vs 10.0±3.01 reps; 6-min walk test-6MWT: 312.6±100.9 vs 231.9±131.5 m; Functional Rating Scale for Symptoms of Dementia-FRSSD: 4.6±2.6 vs 9.2±3.3; $p < 0.05$) was observed in CG at the end of the experimental period. Significant improvements ($p < 0.05$) were revealed in IG compared to CG regarding CTS, 6MWT (428.8±93.9 vs 231.9±131.5 m), FRSSD (4.2±3.8 vs 9.2±3.3) and GDS, while no differences ($p > 0.05$) were found between groups in Handgrip (11.94±6 vs 11.35±5.6 kg) and Mini-Mental State Exam (21.8±4.7 vs 19.5±6.07) at the end of the experimental period.

CONCLUSIONS: A 9-month exercise training program leads to significant improvements in physical and mental functioning of nursing home patients in early and middle stages of dementia. Further studies are needed to reveal the optimum characteristics of the exercise training so as to maximize its benefits in physical and mental performance of patients in various stages of dementia.

Aerobic Interval Training Integrated In Collaborative Care Of Outpatients With Schizophrenia: One-year Outcomes

Mathias F. Brobakken, Mona Nygård, Ismail Cüneyt Güzey, Gunnar Morken, Solveig K. Reitan, Jørn Heggelund, Einar Vedul-Kjelsaas, Eivind Wang. *Norwegian University of Science and Technology, Trondheim, Norway.*
Email: mathias.f.brobakken@ntnu.no
(No relevant relationships reported)

Although aerobic interval training (AIT) is recognised to attenuate the risk of cardiovascular disease (CVD) and premature mortality, it appears that it rarely arrives at patients' doorsteps. **PURPOSE:** This study investigated 1-year outcomes when AIT was integrated with municipal and specialised health service in collaborative care of outpatients with schizophrenia. **METHODS:** Forty-eight outpatients (28 men, 35±10 (SD) years; 20 women, 35±12 years) with schizophrenia spectrum disorders (ICD-10) were randomised to either a collaborative care group provided transportation and training supervision and walking/running 4x4-minutes at ~90% of peak heart rate (HR_{peak}) 2 d-wk⁻¹ (TG), or a control group (CG) given 2 introductory AIT sessions

and advised to continue training. **RESULTS:** Directly assessed peak oxygen uptake ($\dot{V}O_{2peak}$) increased in the TG (3-months: 2.7±3.1 mL·kg⁻¹·min⁻¹; 6-months: 3.2±3.0 mL·kg⁻¹·min⁻¹; 1-year: 3.3±3.1 mL·kg⁻¹·min⁻¹; all $p < 0.001$; different from CG: $p < 0.05$ -0.001). In contrast, $\dot{V}O_{2peak}$ remained unchanged (3/6-months) and decreased (1-year: -1.8±3.8 mL·kg⁻¹·min⁻¹, $p < 0.05$) in the CG. One-year cardiac effects revealed increased HR_{peak} (3±7 b·min⁻¹, $p < 0.05$; different from CG: $p < 0.01$) in the TG and decreased HR_{peak} (-3±7 b·min⁻¹, $p < 0.05$) in the CG, while peak stroke volume tended to be higher (0.87±2.15 mL·b⁻¹, $p = 0.12$) in the TG compared to the CG. Conventional risk factors (body weight, waist circumference, blood pressure and lipids/glucose) were unaltered. One-year regular AIT rates were 15/25 (TG; different from CG: $p < 0.0001$) and 0/23 (CG), respectively. **CONCLUSIONS:** AIT was successfully integrated in long-term collaborative care of outpatients with schizophrenia, advocating this model for aerobic capacity improvement and CVD risk reduction in future treatment.

Effects Of PTSD And MDD Comorbidity On Psychological Changes During Surf Therapy Sessions

Nicholas P. Otis¹, Kristen H. Walter², Lisa H. Glassman¹, Travis N. Ray¹, Betty Michalewicz-Kragh³, Cynthia J. Thomsen². ¹*Naval Health Research Center & Leidos, San Diego, CA.* ²*Naval Health Research Center, San Diego, CA.* ³*Naval Medical Center San Diego, San Diego, CA.*
Email: nicholas.p.otis.ctr@mail.mil
(No relevant relationships reported)

PTSD is more likely to be accompanied by another psychological disorder (most commonly depression) than to occur alone, and those with this comorbidity exhibit more severe psychological outcomes compared to those with a single disorder. Exercise-based interventions that occur in the natural environment, such as surf therapy, have preliminarily been shown to improve psychological outcomes in service members/veterans with PTSD or major depressive disorder (MDD); however, previous research has not yet examined the effectiveness of these programs for those with both disorders. **PURPOSE:** This study compared changes in depression/anxiety and positive affect during surf therapy sessions between active duty service members with comorbid PTSD and MDD and those with either disorder alone. **METHODS:** Probable PTSD and MDD diagnoses were determined using *Diagnostic and Statistical Manual of Mental Disorders, 5th Edition* criteria applied to baseline self-report measures. Study outcomes were assessed using validated self-reports (Patient Health Questionnaire-4 and Positive Affect Schedule) completed before and after each of 6 weekly surf therapy sessions. Longitudinal repeated measures data was analyzed using multilevel modeling. **RESULTS:** From pre-to-post session, both the comorbid and single disorder groups reported significant improvements in symptoms of depression/anxiety and positive affect ($ps < .001$). However, those with comorbid PTSD and MDD experienced significantly greater reductions in depression/anxiety ($\beta = -1.22$, $p = .028$) and significantly greater improvements in positive affect ($\beta = 3.94$, $p = .046$) compared with the single disorder group. **CONCLUSIONS:** Surf therapy appears to have global effects on psychological symptom reduction, and may be a useful adjunctive intervention for the treatment of comorbid PTSD and MDD in both clinical and community health settings.

Does Body-mind Exercise Has Less Effect Than High-intensity Interval Training?

Dong Zhu¹, Su-yong Yang¹, Ding Xu², Ke Xiao³, Xiao-ying Tan¹, Yan-guang Yang¹, Xiao-wu Pang¹, Tian-yuan Wang¹, Jia-bin Wang¹. ¹*Shanghai University of Sport, Shanghai, China.* ²*Shanghai Drug Administration, Shanghai, China.* ³*Shanghai Gaojing Drug Compulsory Detoxification and Rehabilitation Center, Shanghai, China.*
Email: zhudong@hotmail.com
(No relevant relationships reported)

Objective: High-intensity interval training (HIIT) has recently attracted considerable interest as a time-efficient approach to improving physical and psychological health. The aim of this study was to compare the physical and psychological effect of substance abusers by HIIT or body-mind exercise. **Methods:** 120 Methamphetamine (Meth) dependent individuals from a compulsory rehabilitation center in Shanghai were randomly assigned to HIIT group (experimental group) and body-mind exercise group (control group). The subjects in the experimental group received HIIT training including rope jumping, running, weight lifting and basketball game, 1 hour a day, 3 times a week. The control group received Tai Chi practice, the duration of each session and the repetitions per week were the same as those of the experimental group. Subjects in both groups took part in 6 months intervention. The outcomes of Amphetamine Withdrawal Symptom Questionnaire (AWQ), blood pressure (BP), vital capacity (VC) and fitness test were measured at the

baseline, 3 months, 6 months. Data analysis was applied with SPSS 22.0, a two-way repeated measures analysis of variance (ANOVA) was applied to test whether the treatments were different after 6 months.

Results: At the baseline, there were no significant differences between the two groups regarding to age, years of drug use, scores of AWS, BP, VC and fitness. The significant changes were found after 6 months. The score of AWQ in experimental group was 8.84 ± 0.78 and in control group was 12.04 ± 0.76 , $p = 0.004$. The blood pressure, vital capacity, hand grip, one-leg-stand with eyes close, reaction time were found significantly improved after 6 months intervention in both groups. However, there was no significant differences between the two groups.

Conclusion: HIIT and body-mind exercise have similar effect for Meth dependent individuals except the score of AWQ, the result suggests that the body-mind exercise might be a safer and optional choice for whom don't want to engage in vigorous exercise.

2503 May 29 10:30 AM - 10:45 AM

Aerobic Exercise Acutely Reverses Negative Mood Occurring In The Mid-luteal Phase Of The Menstrual Cycle

Jessica A. Freemas, Marissa N. Baranuskas, Joel T. Greenshields, John S. Raglin, FACSM, Timothy D. Mickleborough, Zachary J. Schlader, FACSM. *Indiana University, Bloomington, IN.* (Sponsor: Zachary Schlader, FACSM)
Email: jffreemas@iu.edu
(No relevant relationships reported)

Purpose: Over 80% of women report a more negative mood state during the luteal phase compared to the follicular phase of their menstrual cycle. Mood is acutely improved following aerobic exercise. Thus, aerobic exercise may be capable of normalizing mood during the luteal phase of the menstrual cycle. We tested the hypothesis that prior aerobic exercise would eliminate differences in mood state between the mid-luteal and mid-follicular phases of the menstrual cycle.

Methods: 12 recreationally active eumenorrheic women (25 ± 6 y) completed ~30 min of aerobic exercise, which consisted of 10 min of steady state aerobic exercise and an 8 km cycle time trial, during the mid-follicular and mid-luteal phases of the menstrual cycle. Participants completed a Profile of Mood State Questionnaire (POMS) pre-exercise and 20 min post-exercise. The POMS provided indices of confusion, tension, depression, vigor, fatigue and anger, from which total mood disturbance (TMD) was calculated (higher scores = more negative mood). Data are presented as T-scores (a.u.).

Results: Pre-exercise tension (42 ± 10 vs. 39 ± 7 , $P < 0.01$) and anger (41 ± 4 vs. 39 ± 4 , $P = 0.04$) were elevated and vigor (35 ± 11 vs. 42 ± 11 , $P < 0.01$) and TMD (174 ± 26 vs. 162 ± 31 , $P < 0.01$) were lower in the mid-luteal vs. the mid-follicular phase. Confusion and depression did not differ between phases pre-exercise ($P \geq 0.56$). Fatigue did not differ between phases at any time ($P \geq 0.57$) nor change from pre- to post-exercise ($P \geq 0.15$). Confusion, tension, depression, and vigor decreased from pre- to post-exercise in the mid-luteal and mid-follicular phases ($P < 0.01$), but there were no differences between phases at post-exercise ($P \geq 0.06$). Anger decreased from pre- to post-exercise in the mid-luteal (38 ± 1 , $P < 0.01$) but not the mid-follicular phase (37 ± 1 , $P = 0.08$), which eliminated differences between phases post-exercise ($P = 0.57$). TMD decreased from pre- to post-exercise in both phases ($P < 0.01$) and there were no differences between the mid-luteal (142 ± 17) and mid-follicular (136 ± 16) phases post-exercise ($P = 0.16$).

Conclusion: Women experience a more negative mood state during the mid-luteal compared to the mid-follicular phase. Aerobic exercise acutely normalizes these differences in mood state by eliminating menstrual cycle dependent differences in vigor, anger, and tension.

2504 May 29 10:45 AM - 11:00 AM

The Effects Of Ecologically-Valid Resistance Exercise Training Among Young Adults With Analogue Generalized Anxiety Disorder

Brett R. Gordon¹, Cillian P. McDowell², Mark Lyons¹, Matthew P. Herring, FACSM¹. ¹University of Limerick, Limerick, Ireland. ²Trinity College Dublin, Dublin, Ireland. (Sponsor: Matthew P. Herring, FACSM)
Email: brett.gordon@ul.ie
(No relevant relationships reported)

PURPOSE: This randomized controlled trial examined the effects of eight weeks of ecologically-valid resistance exercise training (RET) compared to wait-list control among 27 young adults (26.6 ± 4.5 y; 18 female) with analogue Generalized Anxiety Disorder (AGAD; Psychiatric Diagnostic Screening Questionnaire GAD subscale ≥ 6 and Penn State Worry Questionnaire ≥ 45).

METHODS: Fully supervised, ecologically-valid, one-on-one RET sessions designed according to World Health Organization (WHO) and American College of Sports Medicine (ACSM) guidelines, consisting of 2 sets of 8-12 repetitions of

eight exercises, were delivered twice weekly, after a 3 week familiarization. Rating of perceived exertion (RPE) and muscle soreness (1-10) were assessed after each exercise. The primary outcome, remission based on change in AGAD status, was assessed post-intervention, and quantified with number needed to treat (NNT).

Worry and anxiety symptoms were assessed at baseline, week 1, week 4, and post-intervention. Independent samples *t*-tests examined baseline differences between conditions. Paired sample *t*-tests examined changes in 5RM strength. RM-ANOVAs examined differences between RET and wait-list across time. Significant interactions were decomposed with simple effects analysis. Hedges' *d* effect sizes (95%CI) quantified the magnitude of the difference in change between groups across time.

RESULTS: There were no baseline differences between conditions. Attendance was 81%, and compliance was 77% (average RPE = 14.41 ± 1.58 , muscle soreness = 4.40 ± 1.70). Participants significantly increased strength ($F = 6.86$, $p < 0.001$, $d = 1.24$). RET improved AGAD status (NNT = 3, 95%CI: 2 - 17). A significant condition-time interaction was found for worry ($F_{(3,66)} = 3.12$, $p \leq 0.043$, $d = 0.93$ [0.13 - 1.73]), and anxiety symptoms ($F_{(3,66)} = 2.91$, $p \leq 0.046$, $d = 0.71$ [-0.08 - 1.49]). RET significantly reduced worry (mean difference = -6.49 , $p \leq 0.045$) and anxiety symptoms (mean difference = -10.50 , $p \leq 0.001$).

CONCLUSIONS: Ecologically-valid RET, designed according to WHO and ACSM guidelines, improved AGAD status, and elicited large magnitude reductions in worry and anxiety symptoms among young adults with AGAD. This is the first ecologically-valid RET intervention among young adults with clinically relevant anxiety pathology.

2505 May 29 11:00 AM - 11:15 AM

Neural Responsiveness To Reward And Cognitive Control Following An Eight-week Aerobic Exercise Trial For Depression

Christopher J. Brush¹, Greg Hajcak¹, Brandon L. Alderman². ¹Florida State University, Tallahassee, FL. ²Rutgers University, New Brunswick, NJ.
(No relevant relationships reported)

Major Depressive Disorder (MDD) is a common affective disorder that affects nearly 20% of adults and is a leading cause of global disability and disease. Despite demonstrated efficacy of aerobic exercise for depression, there is a poor understanding of clinical and neurobiological mechanisms. Two candidate mechanisms of depression that may be modifiable through aerobic exercise are reward processing and cognitive control deficits. **PURPOSE:** The primary aim was to examine the effects of an 8-week aerobic exercise (AE) program on event-related potential (ERP) indices of reward processing (RewP) and cognitive control (ERN), and symptoms of depression among individuals with MDD. Secondary aims were to determine whether changes in reward (RewP) or cognitive control (ERN) were related to changes in depressive symptoms and whether baseline RewP or ERN could predict the likelihood of an antidepressant response. **METHODS:** Individuals with MDD ($N = 51$; 75% female) were stratified by depressive symptoms and randomized to either moderate-intensity AE ($n = 26$) or light-intensity stretching ($n = 25$) that was completed 3 times per week for 45 min. Depressive symptoms, aerobic fitness, and ERPs were assessed pre and post intervention. **RESULTS:** Compared to stretching, the AE condition resulted in pre-to-post reductions in depressive symptoms ($p < .01$; $\eta_p^2 = 0.17$), while both conditions experienced pre-to-post increases in aerobic fitness ($p < .01$, $\eta_p^2 = 0.14$). Although no mean-level treatment changes in RewP or ERN were observed, there was a relationship between pre-to-post change in ERN and change in depressive symptoms ($r = -0.41$, $p < .01$), indicating a decrease in ERN was related to larger pre-to-post reductions in depressive symptoms. At baseline, a larger ERN was predictive of greater pre-to-post change in depressive symptoms, ($p < .05$, OR = 1.27), while there was a trend for baseline RewP as a predictor of treatment response ($p = .07$, OR = 1.24). **CONCLUSION:** These findings provide support for the antidepressant effects of AE and highlight ERN as a potential neurobiological marker that predicts and tracks the antidepressant response. Future research incorporating predictors of response and examining neurobiological mechanisms may help advance understanding of the effects of exercise as a treatment for depression.

2506 May 29 11:15 AM - 11:30 AM

Walking Away Depression And Anxiety: Results From The Irish Longitudinal Study On Ageing

Cillian P. McDowell¹, Nanette Mutrie², Marie H. Murphy, FACSM³, Matthew P. Herring, FACSM⁴. ¹Trinity College Dublin, Dublin, Ireland. ²University of Edinburgh, Edinburgh, United Kingdom. ³Ulster University, Jordanstown, United Kingdom. ⁴University of Limerick, Limerick, Ireland.
Email: cillian.mcdowell@tcd.ie
(No relevant relationships reported)

Walking is an accessible physical activity that is promoted as a best buy for public health. However, few prospective studies have examined the association between walking and depression, and none have investigated Generalized Anxiety Disorder (GAD).

PURPOSE: This study examined associations between walking and incident depression and incident GAD among community-dwelling adults aged ≥50 years in the Republic of Ireland.

METHODS: Participants completed the short form International Physical Activity Questionnaire at baseline and Center for Epidemiological Studies Depression Scale (CES-D) and CIDI-short form at two-year follow-up. Walking doses were categorised based on reported minutes of walking in the prior seven days (None=0 minutes/week; Low=1-209 minutes/week; Moderate=210-419 minutes/week; High=420+ minutes/week). Logistic regression, weighted relative to age, sex, and education and adjusted for age, sex, waist circumference, social class, smoking, moderate and vigorous physical activity, comorbidities, and physical limitations, quantified associations between walking and incident depression (N=4,146; 55.4% female) and GAD (N=3,326; 52.6% female) in participants without depression (CES-D≥16) or GAD (abbreviated Penn State Worry Questionnaire ≥23) at baseline. Likelihood ratio tests examined covariate significance.

RESULTS: Incidence of depression and GAD were 5.0% (n=207) and 0.9% (n=29), respectively. Compared to people who reported no walking, odds (odds ratio, 95% confidence interval) of incident depression were lower among those engaging in Low (0.908, 0.876-0.940; p<0.001), Moderate (0.893, 0.858-0.929; p<0.001), and High (0.897, 0.865-0.931; p<0.001) walking doses. Odds of incident GAD were also lower among those engaging in Low (0.411, 0.335-0.406; p<0.001), Moderate (0.710, 0.6432-0.786; p<0.001), and High (0.614, 0.555-0.678; p<0.001) walking doses. All covariates significantly contributed to the models (p<0.001).

Conclusion: Among a large, nationally representative sample of older adults, self-reported walking was associated with lower odds of incident depression and GAD independent of moderate and vigorous intensity physical activity. These findings support policy and national guidelines in promoting walking for its mental health benefits.

E-13 Clinical Case Slide - Knee II

Left Knee, Leg Pain After A Hand Cycling Accident

Cameron Fausett, Alexander Sheng. *Shirley Ryan Ability Lab, Chicago, IL.* (Sponsor: Dr. Joseph Ihm, FACSM)

Email: cfausett@sralab.org

(No relevant relationships reported)

HISTORY:

A 56 year old female with past medical history of Ehlers-Danlos Syndrome and stroke with residual left hemiparesis sustained a left knee and leg injury while hand cycling. Patient was on a ride when she collided with another cyclist, causing her to fall onto her left leg and thigh. She reported immediate pain, swelling and bruising of her left knee and leg. She presented to her primary care physician a few days later due to persistent pain. X-rays were negative for fracture. Patient had no new numbness or tingling. Her strength in her left lower extremity is minimal due to her stroke but she had noticed more difficulty with transfers due to pain

PHYSICAL EXAMINATION: There was a large area of swelling on the lateral aspect of the distal left thigh that was firm and tender to palpation. Left knee showed no obvious deformity. There was diffuse tenderness to palpation over the medial and lateral knee and proximal tibia. There was no erythema or effusion. She had full knee range of motion in flexion/extension without pain. There was no ligamentous laxity in varus/valgus testing. Anterior and posterior drawer, Lachman's/McMurry's tests were negative. Strength was 1/5 in hip flexion, 0/5 in knee flexion/extension which, per patient report, was baseline. Sensation was intact to light touch.

DIFFERENTIAL DIAGNOSIS: Femoral/tibial fracture, bone contusion, medial/lateral collateral ligament sprain, meniscus injury

TEST AND RESULTS: MRI KNEE LT WO CONTRAST

There is a T2 hyperintense 1.8 x 8.1 cm (transverse by AP) fluid collection layering over the iliotibial band and superficial fascial biceps femoris, with free floating internal fat lobules. Favored to represent a Morel-Lavallee lesion. The menisci, cruciate and medial collateral ligaments, lateral collateral ligamentous complex and extensor mechanism are intact.

FINAL WORKING DIAGNOSIS: Morel-Lavallee lesion of left thigh

TREATMENT AND OUTCOMES:

Patient referred to plastic surgery who recommended percutaneous drainage. She underwent ultrasound guided drainage of 25 ml of serosanguinous fluid. At follow up no further fluid collection seen on ultrasound. Pain was resolving. Patient advised to wear compression garment to assist with healing. Cleared to return to activity as tolerated. Patient seen one year later with resolved symptoms and physical exam findings.

2511 May 29 9:50 AM - 10:10 AM

Mechanical Locking Of The Knee: Retired Rugby Union Player-What Is The Catch?

Pierre L. Viviers, FACSM, Elton Wayne Derman, FACSM.

Stellenbosch University, Stellenbosch, South Africa.

Email: plviviers@sun.ac.za

(No relevant relationships reported)

HISTORY: A 29-year-old male retired rugby player presented to the sports medicine clinic during an emergency appointment with his right knee acutely locked in full flexion. He was bending into a squat position when he felt something "giving way". He was subsequently unable to stand or straighten his knee. There was no acute trauma reported in relation to his present complaint. There was no pop or swelling of the knee nor pain or discomfort. Previously, he sustained multiple knee injuries, including patella dislocation, patella-femoral tendon and medial collateral ligament injury which resulted in surgery complicated by post-operative intra-articular sepsis and septicemia. He reported a previous dislocation of the patella during rugby matches at school.

PHYSICAL EXAMINATION: Examination revealed a young, healthy male with his right knee in full flexion. Active and passive extension were impossible. There was no obvious swelling or joint line tenderness yet, comprehensive examination of the knee was impossible due to the locked knee. The ankle, hip, lower back found to be normal. Further systemic examination was unremarkable.

DIFFERENTIAL DIAGNOSIS: Displaced meniscus tear. Loose bodies. Osteochondral fragment. Soft tissue mass. **TEST AND RESULTS:** 1) Referral to orthopedic surgeon for urgent consultation. Immediate arthroscopic examination and surgery revealed a large intra-articular effusion. The medial condyle and patella showed cartilage degeneration. A soft tissue mass was discovered in the intercondylar notch causing notch impingement. It was excised and sent for histology. 2) Histological analysis revealed that the mass consisted of pigmented villonodular synovitis

FINAL WORKING DIAGNOSIS: Pigmented villonodular synovitis **TREATMENT AND OUTCOMES:** Started with physiotherapy rehabilitation immediately post-operative and continued for 6 weeks.

Immobilized-partial weight bearing on crutches (2 weeks). Functional return - swimming (2 weeks), jogging (6 weeks). The patient returned to jogging and completed several 10 km events without any discomfort. Yet he experienced marked pain and discomfort in events more than 10 km. He does not partake in any sport with a collision nature. Long term follow-up needed to monitor for growth recurrence.

2512 May 29 10:10 AM - 10:30 AM

Inclusion Of Wearable Sensors In The Treatment Of Patellofemoral Pain

Lindsay Wasserman. *Spaulding National Running Center, Cambridge, MA.* (Sponsor: Irene Davis, FACSM)

Email: lwasserman@partners.org

(No relevant relationships reported)

TEXT:

HISTORY: 32 yr. old male with 2 yr history of bilateral (BIL) patellofemoral pain (PFP) which began at the end of a marathon. Symptoms resolved with rest. However, 1 year later, patient was training for another marathon. Speed work was added to this training and the patient alternated between running in cushioned and highly cushioned shoes. PFP developed quickly stopping the patient within 3 miles of running. Knee pain increased up to 8/10 with running, prolonged sitting, stairs and hiking.

PHYSICAL EXAM:

1. Weakness of the hip extensors, abductors and external rotators BIL and core muscles
 2. (+) Obers & Thomas test
 3. (+) Patella compression test with medial patella tenderness BIL
 4. Weakness of the calves, and foot intrinsic BIL
 5. Running Gait Analysis
- Excessive and prolonged foot pronation through stance BIL

Decreased knee flexion at footstrike BIL

Increased hip ADD BIL

R CPD and L ipsilateral trunk lean

Significantly high vertical rates of loading

WORKING DIAGNOSIS

PPF due to increased impact loads during landing, as well as excessive hip ADD, CPD and trunk lean due to poor dynamic control of the foot and hip associated with weakness. These issues of loading and alignment have both been shown to contribute to patellofemoral pain.

TREATMENT:

Pre Gait Retraining

1. Transition to minimal shoes for walking to promote foot/ankle strength
2. Improve foot/ankle function and control with heel raises, balance exercises and plyometrics
3. Increase hip/core strength to improve dynamic alignment

Gait retraining

1. *Wearable sensor feedback*: an accelerometer was attached to the ankle and set to sound an alarm when impact exceeded a set threshold. Initially the threshold was set to 6 gs, but reduced to 5 gs as the patient's ability to control his landings improved
2. *Mirror feedback*: patient was instructed to activate his arch muscles and his gluteals as he ran and was provided mirror feedback to reinforce this. Feedback was gradually faded.

OUTCOME: Patient had 9 pre-gait visits and 12 visits of gait retraining with focus on soft landings and improved alignment. Pt's rates of loading reduced and was able to exhibit reduced hip ADD, CPD, trunk lean, and pronation. The patient is able to run 30 minutes pain free. This case demonstrates the value of using wearable sensor devices to assist in gait retraining.

2513 May 29 10:30 AM - 10:50 AM

Rare Knee Injury In A Hurdler

Ravi M. Shah¹, Marc Breslow², Kaleigh Ann Suhs¹. ¹Advocate Lutheran General Hospital, Park Ridge, IL. ²Illinois Bone and Joint, Niles, IL.

(No relevant relationships reported)

History: 18-year-old female with history of asthma presented to the ED with injury to knee. About 20 minutes prior to arrival she tripped over a hurdle and landed awkwardly. Immediately felt pain to the left knee and left hip and had an obvious left knee deformity. The high school trainer was able to palpate distal pulses. EMS was called and patient was placed in an air splint and transferred to the ED. **Physical Exam:** In the ED Patient had stable vital signs. She had notable deformity to the left knee, left lower limb notably shorter than right and externally rotated with dimpling at the medial knee. Unable to flex at the left knee joint. Tenderness at the left knee joint, no erythema, no swelling. Able to wiggle toes, dorsiflex and plantarflex. L3-S1 Sensation intact. Dorsalis pedis and posterior tibialis pulses 1+ on the left, weaker than the right. Brisk cap refill. **Differential Diagnoses:** 1. Anterior Knee Dislocation with multiple ligamentous damage with vascular compromise. 2. Anterior Knee Dislocation with multiple ligamentous damage without vascular compromise. 3. Anterior Knee Dislocation with minimal ligamentous injury. 4. Hip Fracture/dislocation **Tests and Results:** 1. **XR KNEE LT 2V IMPRESSION:** Complete dislocation at the left knee joint. Distal femur displaced posteriorly with respect to proximal tibia. No fractures noted. No radiopaque foreign body. 2. **XR PELVIS 1V IMPRESSION:** Normal Xray, no fracture, dislocations or deformities noted. 3. **XR KNEE LT 2V Post Reduction IMPRESSION:** Relocation of previously seen dislocation. Normal alignment noted. No fractures. **Final Working Diagnosis:** Anterior Knee Dislocation with multiple ligamentous damage and vascular compromise. **Treatment and Outcome:** 1. Pt underwent a closed reduction in the ED with sedation by ortho and ED physicians. 2. Distal pulses improved and patient was placed in an immobilizer. 3. Vascular surgery was consulted, and a CTA of the lower extremity was done which showed no vascular injury. 4. Pt had external fixation procedure with fluoroscopy for knee stabilization. 5. Pt was followed up with outpatient Ortho. External fixation was removed 2-3 months after the surgery. 6. Pt was placed in an immobilizer and was started with physical therapy. Further management pending orthopedic evaluation and patient progression.

2514 May 29 10:50 AM - 11:10 AM

Knee Injury-Football

Andrea Dockry MD, Michael Baria MD MBA. *Ohio State University Wexner Medical Center, Columbus, OH.*
Email: andrea.dockry@osumc.edu

(No relevant relationships reported)

HISTORY: A 17 year old high school football offensive lineman with PMH of patellar dislocation, DVT, and heterozygous positive for Factor V Leiden mutation (FVLM) sustained a knee injury after hit in the posterior knee. He experienced immediate swelling and anterior knee pain, worse with weight bearing. He was able to bear weight after this injury but did not resume practice. He denied hearing or feeling a pop. He denied symptoms of instability and paresthesia. Athletic trainer diagnosed him with patellar dislocation and reduced his patella.

PHYSICAL EXAMINATION: Examination in the sports medicine clinic revealed 17 year old male in no acute distress, alert, oriented, with affect appropriate to mood. He was neurovascularly intact in all limbs. His left knee exhibited an effusion. There was no instability on varus or valgus testing. Lachman and patellar apprehension testing was negative. His skin was warm, dry, without erythema, induration, or rashes. There was no calf tenderness or edema.

DIFFERENTIAL DIAGNOSIS:

Patellar Dislocation

ACL rupture

PCL rupture

PLC injury

MCL sprain

TESTS AND RESULTS

MRI L knee without contrast: Moderate joint effusion with synovitis. Remote MCL sprain. Ruptured Baker's cyst. Large osteochondral impaction injury of the medial facet of the patella with disruption of the medial retinaculum and patellofemoral ligament compatible with prior patellar dislocation. Fissuring along the medial facet of the patella. Large osteochondral impaction injury of the lateral femoral condyle with an adjacent osseous fragment. Mild tendinosis of the proximal infrapatellar tendon

FINAL/WORKING DIAGNOSIS

Patellar dislocation in patient with PMH of heterozygous positive FVLM and prior DVT after previous patellar dislocation

TREATMENT AND OUTCOMES

1. Protection, relative rest, ice, compression, and elevation. Early ambulation as tolerated.
 2. Orthopedic surgery referral due to recurrent patellar dislocation
 3. We were unable to immediately get in contact with patient's hematologist, but we spoke to anticoagulation pharmacist who recommended Xarelto 10 mg BID for 14 days for DVT prevention.
 4. Hematology follow up for anticoagulation duration
 5. 50 calf pumps per hour to further reduce risk of recurrent DVT
 6. Patient was educated on the signs of a DVT
- No grant funding was received for this clinical case.

E-14 Clinical Case Slide - Thigh and Leg I

Friday, May 29, 2020, 9:30 AM - 11:10 AM

Room: CC-2022

Leg Injury—ATV Accident

Hunter D. Haley, Jason L. Zaremski, FACS. *University of Florida, Gainesville, FL.*

(No relevant relationships reported)

HISTORY: A 16-year-old female presented with a 2 week history of right knee and lower leg pain following an ATV accident. Outside radiographs of the right tibia-fibula, femur, and right foot were reported as normal. She had noted worsening knee pain as well as tingling in her 2nd-5th toes. She was using crutches and non-weight bearing (WB) at presentation.

PHYSICAL EXAMINATION: Exam revealed 3/5 muscle strength with great toe flexion/extension, 3/5 strength with ankle dorsiflexion, and 4/5 strength with plantar flexion, inversion, and eversion. Decreased sensation noted in the right 1st web space as well as the lateral, medial, and posterior lower leg. Tinel's sign positive at fibular head. Lateral proximal tibia and lateral knee joint line tender to palpation. 4/5 strength with painful flexion/extension of knee, but range of motion (ROM) intact. She had 2+ posterior tibialis and dorsalis pedis pulses.

DIFFERENTIAL DIAGNOSIS: 1) Proximal Lateral Tibia bony stress injury 2) Peroneal Neuropathy 3) Intra-articular knee derangement

TEST AND RESULTS: Due to examination, a knee MRI was obtained as was an EMG/Nerve Conduction Study (NCS) to assess the peroneal nerve. MR Knee revealed a non-depressed subchondral fractures of anterior lateral tibial plateau and femoral condyle. Semimembranosus tendon partial tear near tibial insertion. Grade 1 MCL injury. The EMG/NCS revealed a mild, acute-subacute, peroneal neuropathy.

FINAL WORKING DIAGNOSIS: Non-displaced fractures of lateral tibial plateau and lateral femoral condyle with peroneal neuropathia.

TREATMENT AND OUTCOMES: 1) Initial visit- Ankle Foot Orthosis (AFO) and hinge knee brace provided while MRI and EMG/NCS pending. Remained non-WB with crutches. 2) After MRI and EMG/NCS 1 week later- began home passive and active assisted ROM exercises at home. Continued AFO and crutches when not at home. 3) 4 weeks after first evaluation- began toe-touch WB with progression to partial WB as tolerated and also began PT with right knee/ankle stretching and strengthening. Continued to wear AFO to allow for peroneal nerve healing as she progressed to WB as tolerated. 4) 3 months post injury- AFO removed for activities of daily living but advised against exertional impact activity while completing PT.

2519 May 29 9:50 AM - 10:10 AM

Posterior Thigh Injury-Tennis

Dayna Yorks, Monica Rho. *Shirley Ryan AbilityLab/ Northwestern University Feinberg School of Medicine, Chicago, IL.* (Sponsor: Joseph Ihm, MD, FACSM)
Email: dyorks@sralab.org
(No relevant relationships reported)

HISTORY: A 76-year-old male was sprinting for the ball one hour into playing singles tennis with a score of 6-6 when he developed acute onset right posterior mid-thigh pain. He denied an audible “pop.” He stopped playing, took ibuprofen, and applied ice upon returning home. He continued to rest and apply ice. Eight days later, he presented to the outpatient sports medicine clinic with improved pain rated 1-2/10, but with worsened swelling and bruising of the right distal posterior thigh. He denied back pain, hip pain, lower extremity numbness, tingling, or weakness. He denied a history of prior hamstring injury. He typically plays doubles tennis three times/week for two hours at a time. This was his second time playing singles this year.

PHYSICAL EXAMINATION: Examination revealed bruising along the popliteal fossa and distal hamstring on the right. There was palpable swelling and mild tenderness along the medial aspect of the posterior mid-thigh on the right. There was no tenderness to palpation of the ischial tuberosity. Knee flexion strength was 4/5 on the right, 5/5 on the left. Gait was non-antalgic. There was pain with resisted right knee flexion at 135 degrees, with lesser discomfort at 90 and 45 degrees. Bilateral lower extremities were warm with intact sensation and +2 patellar and achilles reflexes.

DIFFERENTIAL DIAGNOSIS:

1. Hamstring muscle strain or tear
2. Hamstring tendon avulsion injury
3. Femoral stress fracture
4. Adductor magnus strain
5. Referred pain from the lumbosacral spine, hip joint, or sacroiliac joint
6. Ischial bursitis

TESTS AND RESULTS:

Right Hamstring Ultrasound:

-Hypoechoogenicity of the right semimembranosus muscle consistent with partial tear
-Intramuscular calcification in the area of the tear

MRI Pelvis Without Contrast:

-Suggestion of grade 2 hamstring muscle strain centered near the central myotendinous complex of one of the hamstring tendons, likely the semimembranosus

FINAL WORKING DIAGNOSIS:

Partial tear of the semimembranosus muscle with calcification

TREATMENT AND OUTCOMES:

1. Rest for 2 weeks post-injury.
2. Walk and cycle if tolerated 3-4 weeks post-injury. No tennis.
3. Started physical therapy 4 weeks post-injury for progressive hamstring strengthening and return to tennis and exercise.

2520 May 29 10:10 AM - 10:30 AM

Knee Pain And Swelling - Volleyball Player

Sarah Weinstein, Karin VanBaak. *University of Colorado, Aurora, CO.* (Sponsor: Morteza Khodae, FACSM)
Email: sarah.weinstein@cuanschutz.edu
(No relevant relationships reported)

History:

An 18 year old volleyball player presented with acute swelling and pain of her right knee with associated nausea, vomiting, and subjective fevers. Aside from an abrasion beneath her knee sustained during practice 2 weeks prior, she denied inciting injury or trauma. She complained of knee tightness, but denied feelings of instability or mechanical symptoms. She denied history of skin or soft tissue infections.

Physical exam:

On initial examination, she was febrile to 102°F (38.9°C). She had notably increased warmth and erythema along the lateral aspect of her right knee with tenderness to palpation. She had evidence of a healed abrasion inferior to her right knee without an associated joint effusion. There did appear to be swelling localized to the lateral aspect of her knee. She had full range of motion of her right knee without any indication of ligamentous injury. Her gait was non-antalgic.

Differential diagnosis:

1. Septic prepatellar bursitis
2. Necrotizing infection (cellulitis, myositis, fasciitis)
3. Septic arthritis
4. Morel-Lavallée Lesion
5. Reactive arthritis (gonococcal, chlamydial)

Tests and results:

1. Pertinent labs: White blood cell count 27,000 X 10⁹/L, sodium 127 mEq/L, potassium 3.2 mEq/L
2. Blood cultures negative times 2
3. Lower extremity MRI: Extensive cellulitis and probable phlegmon in subcutaneous fat throughout the distal thigh and knee; myositis in the distal vastus lateralis muscle and biceps femoris
4. Gram stain from I&D right thigh: Positive strep pyogenes (group A)
5. Surgical findings consistent with necrotizing fasciitis.

Final/working diagnosis:

Subacute necrotizing fasciitis

Treatment and outcomes:

1. She was initially treated with broad spectrum antibiotics, subsequently tailored to culture and sensitivities.
2. She underwent three surgical explorations to assess underlying muscle and fascia, including I&D of necrotic tissue along iliotibial tract.
3. With both subjective and objective improvement, she was discharged from the hospital to complete one week of IV Ceftriaxone.
4. She was cleared to start her rehabilitation and progressed to walk/jog/jump for four weeks focusing on quadriceps strengthening.
5. After one week of non contact play and sport specific drills, she returned to full contact practice six weeks after hospital discharge.

2521 May 29 10:30 AM - 10:50 AM

Anterolateral Thigh Pain - Soccer And Ice Hockey

Marissa L. Dombovy-Johnson, Karen L. Newcomer, FACSM.
Mayo Clinic, Rochester, MN.
Email: dombovy-johnson.marissa@mayo.edu
(No relevant relationships reported)

HISTORY: A 13-year-old male presented with left anterolateral thigh pain that initially occurred during a soccer game. He felt as if he “pulled a muscle” and finished playing the game, but 2 weeks later the pain returned during ice hockey practice. The pain was so severe that he couldn’t finish practice. Over the next two weeks until his clinic visit, the pain kept him out of gym class and ice hockey. His pain worsened as the day went on, while improving with Ibuprofen use.

PHYSICAL EXAMINATION: Antalgic gait, with exacerbation of pain on toe-walking. Tenderness to palpation along the distal aspect of the left greater trochanter. Left hip range of motion limited by pain in flexion and internal rotation. FABER and Stinchfield tests reproduced left lateral thigh pain.

DIFFERENTIAL DIAGNOSIS:

- Iliotibial band syndrome
- Greater trochanteric bursitis
- Slipped Capital Femoral Epiphysis
- Femoroacetabular impingement
- Avulsion fracture

TEST AND RESULTS:

- Left Thigh and Hip Radiographs - Normal
- Left Thigh and Hip MRI - Patchy edema with associated confluent marrow replacing T1 signal within the medial and posterior column of the left acetabulum
- Pelvis CT - 1.8 cm osteolytic lesion within or adjacent to the physis of the left posterior medial acetabulum
- Whole Body Bone Scan - Normal
- ESR and CRP - Normal
- CT Guided Bone Biopsy - Chronic inflammation; Gram stains of tissue and fluid were negative for infection

FINAL WORKING DIAGNOSIS:

- Chronic Nonbacterial Osteomyelitis

TREATMENT AND OUTCOMES:

- Referred to Pediatric Infectious Disease who recommend IV antibiotic treatment due to concern over potential bone destruction from bacterial osteomyelitis and scheduled Ibuprofen
- Patient relapsed after stopping Ibuprofen
- Pediatric Rheumatology evaluated and recommended treatment with Naproxen BID for 2 months, with complete symptom resolution at end of course

- Patient has remained symptom free 7-months post-NSAID treatment and back to playing soccer/ice hockey

2522 May 29 10:50 AM - 11:10 AM
Progressive Post-traumatic Leg Pain In An Ncaa Division 1 Basketball Player

Avinash Sridhar. *University of Virginia, Charlottesville, VA.*
 (Sponsor: John M. MacKnight, MD, FACSM)
 (No relevant relationships reported)

HISTORY:

A 19-year-old male NCAA Division 1 college basketball player sustained two blunt force injuries to the anterior portion of his right thigh during practice. This area was struck by an opponent's knee in both events. He had a similar injury to this area the week prior but otherwise has had no previous issues with his right lower extremity. After the second collision, he continued to participate in drills until his pain progressed to the point when he became unable to bear weight on his right leg over the course of 1.5 hours. He was then taken to the emergency department for further evaluation.

PHYSICAL EXAMINATION: Height: 6'11"

Examination of the right lower extremity in the emergency department was remarkable for significant swelling of the anterior portion of the right thigh. The anterior compartment was exquisitely tender and firm with minimal compression. The medial and posterior compartments were non-tender and easily compressible. The right foot was warm and well-perfused with 2+ dorsalis pedis and posterior tibial pulses. Sensation was intact to light touch in the L4-S1 nerve distribution. He was able to dorsiflex and plantarflex his right foot but was unable to extend his knee. He was not able to ambulate and his pain worsened over the next hour.

DIFFERENTIAL DIAGNOSIS:

1. Right anterior thigh hematoma
2. Anterior thigh compartment syndrome
3. Quadriceps femoris muscle group tear

TESTS AND RESULTS:

- CBC: Hb 12.6, Hct 36.8
- CMP: CO2 19, BUN 27- PT 12.1, PTT 29.6

- Ultrasound right thigh: Large heterogeneous subcutaneous anterior thigh hematoma measuring 27 x 6 cm. No flow is visualized within. Visualized vasculature is patent on color Doppler imaging. Patent middle right femoral vein and artery

FINAL/WORKING DIAGNOSIS: Right anterior thigh hematoma with developing anterior compartment syndrome, query underlying bleeding diathesis

TREATMENT AND OUTCOMES:

1. Urgent surgical treatment in the operating room for right anterior thigh compartment release with irrigation and evacuation of hematoma
2. Post-operative care and knee immobilizer
3. Touch-down weight bearing of right lower extremity
4. Indomethacin 25 mg PO TID for heterotopic ossification prophylaxis
5. Gradual return to sport after medical and surgical clearance

Run Out Blood Pressure: The Correlation Between Physical Activity And Blood Pressure And Sit Time

Megan L. Conner, Constance Haynes, Jonathan Williams, Larissa Boyd, Melissa Powers. *University of Central Oklahoma, Edmond, OK.*

Email: mconner7@uco.edu

(No relevant relationships reported)

The implementation of the new American College of Cardiology (ACC) and American Heart Association (AHA) blood pressure guidelines has added to the increase in the number of individuals classified as hypertensive. Increasing physical activity and reducing sit-time is recommended to combat hypertension. **PURPOSE:** The purpose of this study was to evaluate the correlation between physical activity (PA) and sit-time (ST) and blood pressure (BP) in university employees. It was hypothesized that there would be a significant inverse relationship between PA and BP and a direct relationship between ST and BP. **METHODS:** In this study the participants were faculty and staff members of a regional university in the Midwest, that were included in a larger workplace intervention ($N=51$). Baseline data was used for this study. The participants completed a self-reported physical activity questionnaire (The International Physical Activity Questionnaire [IPAQ]) to determine their amount of PA engagement ($\text{met}/\text{min}/\text{wk}^{-1}$) and ST. Both systolic and diastolic resting BP (mmHg) were assessed using a stethoscope and sphygmomanometer following at least five minutes of sitting. **RESULTS:** There was a non-significant relationship between PA and BP ($p>0.05$) and ST and BP ($p>0.05$) when analyzed with a Pearson's Product Moment Correlation. To further analyze these results, the participants were classified based on BP as normal ($<120/<80$; $n = 23$), pre-hypertensive ($120-129/<80$; $n = 6$), or hypertensive ($>130/>80$; $n = 22$). However, due to a low amount of participants classified as prehypertensive, only participants classified as normal and hypertensive were analyzed. Differences in PA and ST between the groups based on BP classification were also non-significant ($p>0.05$) when analyzed with an independent t -test. **CONCLUSION:** Self-reported PA and ST were not related to BP in this study; however, other research reports significant correlations. The participants in this study were a part of a larger study including a workplace intervention to decrease sedentary time. This could explain the difference between the results from this study and those from previous studies. Future studies should focus on the relationship between PA and ST and BP in a variety of groups with diverse backgrounds.

2541 Board #2 May 29 9:30 AM - 11:00 AM

A New Model For Introducing Undergraduate Students To Energy Budgets

Marshall D. McCue, Laura Arbutina, John R.B. Lighton. *Sable Systems International, North Las Vegas, NV.*

(No relevant relationships reported)

PURPOSE: Teaching the fundamental concepts of human bioenergetics and energy expenditure (EE) to students can be difficult because the units of measure (e.g., joules/hour, watts, calories, Calories, METS, etc.) are often abstract and intangible. Moreover, the calibration and proper use of respirometry equipment needed to make accurate metabolic measurements can be a college course in itself. We sought to address these issues by developing an easy-to-use, self-calibrating respirometry system that students with no previous experience in respirometry could use to measure their own energy expenditure (in terms of Cal/day) in real time and model their energy budgets.

METHODS: The system was then given to a sophomore biology student and who was asked to make predictions about her EE during various activities (i.e., sitting, standing, reading, texting, cycling, and crunches) and then make actual measurements to test those predictions. The student used the device during the subsequent four weeks to examine her predictions.

RESULTS: Data supported her hypothesis that the EE would not differ between measurement modalities; paired-tests of EE collected using a facemask (5-min.) vs. a whole-body respirometry tent (10-min) showed no significant differences while sitting ($p=0.487$), laying ($df=18$, $p=0.370$), or reading ($p=0.160$). Contrary to her hypothesis there were no differences in EE while resting at different body positions (laying vs. sitting; $df=38$, $p=0.968$), or seated while reading vs. texting ($df=18$; $p=0.414$). Her hypothesis that standing caused higher EE was higher (~15%) than sitting ($df=18$, $p=0.033$) was supported. The two forms of exercise she compared (crunches vs. cycling) revealed much larger (3.4-fold) differences in EE than she predicted ($df=18$, $p<0.001$).

CONCLUSIONS:

Our next step will be to develop student teaching modules so that students working in small groups can practice experimental design and hypothesis testing to learn more about modeling their own energy budgets.

2542 Board #3 May 29 9:30 AM - 11:00 AM

Health And Lifestyle Behaviors Of International Masters World Cup Field Hockey Athletes

Karen A. Croteau, FACSM¹, Nina B. Eduljee¹, Laurie Murphy¹, Stella L. Volpe, FACSM². ¹St. Joseph's College of Maine, Standish, ME. ²Drexel University, Philadelphia, PA.
Email: kcroteau@sjcme.edu
(No relevant relationships reported)

The number of Masters Athletes competing worldwide has increased, yet little research on the health and lifestyle behaviors of Masters Athletes participating in team sports has been undertaken. **PURPOSE:** The purpose of this study was to examine the health and lifestyle behaviors of international Masters Field Hockey Athletes competing in the Masters Field Hockey World Cup in Barcelona, Spain in 2018. **METHODS:** Participants were 488 athletes (301 women, 186 men) from 26 countries, 35 to 76 years of age (51.4±7.9 years). Participants completed the 42-item Health and Wellbeing of Master's Field Hockey Athletes Survey, which asked about demographics, health status, and lifestyle behaviors. **RESULTS:** Mean body mass index was 24.2±2.9 kg/m² (range = 15.2 to 35.3 kg/m²). Participants rated their health as "very good" or "excellent" (86.9%), had no major health conditions (64.8%), medication use (84.2%), or injuries (51.0%). Perceived stress was rated as "rare" or "not at all" by 57.9% of participants. Participants consumed ≥2 fruits (65.3%) and ≥2 vegetables per day (78.3%), daily breakfast (68%), ≤1 sugar-sweetened beverage (80.1%) per day, ≥7 cups of water (43.0%) per day, and ≤2 alcoholic beverages per week (54.9%). Only 5.3% of participants reported using tobacco products. Participants reported ≥7 hours of sleep per night (68.4%), with no or little restless sleep (48.0%). Just under half of participants reported sitting ≥5 hours per day (45.3%). Exercise frequency at ≥3 days per week and ≥30 minutes per session was cited by 92.9% and 93.5% of the sample, respectively. Aside from field hockey, predominant activities included: jogging (62.9%), walking (56.1%), high intensity training (41.4%), and cycling (29.7%). **CONCLUSION:** While there are areas for improvement, Masters Field Hockey Athletes generally practice lifestyle behaviors conducive to positive health.

2543 Board #4 May 29 9:30 AM - 11:00 AM

Perceived Daily Wellness Responses Following Games During A Professional American Football Season

Eric C. Freese¹, Anthony S. Wolfe¹, Timothy J. Roberts², Bridget C. Sopena³, Melissa L. Anderson², Jon K. Davis¹, Steven A. Basham¹. ¹Gatorade Sports Science Institute, PepsiCo Inc., Frisco, TX. ²Gatorade Sports Science Institute, PepsiCo Inc., Bradenton, FL. ³Gatorade Sports Science Institute, PepsiCo Inc., Barrington, IL.
Email: eric.freese@pepsico.com

Reported Relationships: E.C. Freese: Salary; Gatorade Sports Science Institute, PepsiCo Inc. The views in this abstract are those of the authors and do not necessarily reflect the position or policy of PepsiCo, Inc...

Purpose: The purpose of this study was to investigate the perceptual wellness responses and time course of recovery following an American football game and if those responses vary across a professional American football season. **Methods:** Twenty-four male, American football players (25.9 ± 2.7 y) were recruited to complete a standardized daily wellness survey the day before each game (GD-1), game day (GD) and each day following game day (GD+1, GD+2, GD+3, GD+4, and GD+5) during the seven week season. The surveys were obtained each morning via automated text messages to assess perceptions of energy, motivation, stress, and soreness utilizing 10-point Likert scales. A composite daily wellness score (DWS) was created where a higher score indicated better overall wellness. Eight players met the minimum survey response rate set at 70% and were therefore included in the study. All variables were used to determine the time course of perceptual recovery following a game, as well as cumulative recovery across the season. A mixed-effects model was used to measure changes in all markers including the DWS. **Results:** There were no significant interactions for day x week ($p > 0.05$) across the season for the DWS or individual wellness markers. DWS was significantly higher on GD-1 (28.4 ± 6.1; $p < 0.01$) than GD+1, +2, +4, +5 (23.0 ± 6.0; 25.5 ± 6.3; 26.3 ± 6.2; 27.0 ± 6.1, respectively), but lower than GD (31.5 ± 4.1) and similar to GD+3 (26.8 ± 5.5; $p > 0.05$). Perceived energy was significantly lower on GD+1, +3, +4 (5.6 ± 1.9; 5.9 ± 1.9; 5.9 ± 2.1, respectively) compared to GD-1 (6.9 ± 2.1; $p < 0.05$). Perceived motivation was significantly higher on GD (8.5 ± 1.6) compared to GD-1 (7.2 ± 1.9; $p < 0.05$), but then declined on GD+1 (5.3 ± 2.4) and GD+2 (5.7 ± 2.3). Perceived muscle soreness was the lowest on GD (1.9 ± SD) and significantly higher the days following (GD+1: 5.4 ± 2.1; GD +2: 4.1 ± 2.2; GD+4 3.8 ± 1.8; and GD +5: 3.8 ± 1.9) compared to GD-1 (3.0

± 1.6; $p < 0.05$). There was no daily effect on perceived stress ($p > 0.05$). **Conclusions:** Perceptual wellness markers are negatively impacted immediately after and days following a professional football game, and those affects remained consistent across the season. The DWS and individual markers of perceptual wellness may take up to 5 days to return to pregame levels and should be considered when planning player training.

2544 Board #5 May 29 9:30 AM - 11:00 AM

Algorithms, Filters And Corrections Compound Differences Between Multiple Lifestyle Physical Activity Estimates

Marissa Hope Mueller¹, Ruth Chiment¹, Shannon Merkle², Alexandra Haugen¹, Laura Frey-Law¹. ¹University of Iowa, Iowa City, IA. ²United States Army Research Institute of Environmental Medicine, Natick, MA.
Email: marissa.m215@gmail.com
(No relevant relationships reported)

Physical activity (PA) can be objectively and conveniently measured using accelerometers. The use of wrist-worn devices has grown dramatically over the past decade, becoming the preferred choice in many recreational, clinical and research applications. ActiGraph is a leading company in this field, wherein data from accelerometers can be analyzed in their ActiLife software. However, the effects of multiple algorithms, filters and corrections on PA outcomes are not always clear. **PURPOSE:** To examine how lifestyle PA estimates are impacted by multiple scoring methods in a commercial software platform. **METHODS:** We collected lifestyle wrist-worn accelerometer data (ActiGraph GT3X+) from 132 adults with a range of activity levels with and without chronic pain (low back pain, fibromyalgia, pain-free). We analyzed accelerations in ActiLife using multiple algorithms, with and without the wrist correction and proprietary low-frequency extension (LFE) across four PA domains: total EE (METs), active EE (kCal), MVPA time, and steps. Accelerometer and self-reported (International Physical Activity Questionnaire) PA outcomes were compared. **RESULTS:** PA estimates differed notably across most algorithms with highly variable, but typically large effect sizes ($p < 0.05$, median % change = 33.5% [6.9% – 62.6%], $d = 1.04$ [0.60 – 1.45]). The wrist correction reduced PA estimates across all outcomes ($p < 0.05$, % change = -15.0% [-3.9% – -31.8%], $d = 0.56$ [0.31 – 0.93]) save steps and one daily EE algorithm (no change). The LFE increased steps considerably ($p < 0.05$, % change = 72.3%, $d = 1.44$) yet had little effect across all other outcomes ($p < 0.05$, % change = 4.7% [2.9% – 4.9%], $d = 0.13$ [0.11 – 0.14]). Differences were always greater when multiple factors were considered (% change = 89.2% [80.7% – 201.3%]). Correlations between objective and self-reported PA were typically moderate ($p = 0.55$ [0.36 – 0.88]), were further reduced by the wrist correction, and affected minimally by the LFE. **CONCLUSIONS:** Previously-validated scoring methods are not necessarily interchangeable. The wrist correction and LFE inconsistently inflate PA estimates, with variability increasing when multiple factors are considered. Researchers should consistently report detailed methodology to optimize comparisons across studies and to normative guidelines.

2545 Board #6 May 29 9:30 AM - 11:00 AM

Fitness Levels In College-aged Females: A 20-year Follow-up

Ruth N. Henry, Megan D. Jones, Grace A. Zimmerman.
Lipscomb University, Nashville, TN.
Email: ruth.henry@lipscomb.edu
(No relevant relationships reported)

PURPOSE: A decline in fitness levels of both children and young adults has been reported over the last two decades. The purpose of this study was to determine to what extent this claim is true, and which components of fitness may be involved in this decline.

METHODS: Researchers examined several components of fitness, including estimated cardiorespiratory fitness, muscular fitness, percent body fat, and body mass index (BMI) during 1999. Subjects for the original study were 72 college females enrolled in general education fitness classes. The assessment was repeated at the same university in 2019 with 69 college females, also enrolled in general education fitness classes. During both time periods, students were assessed at the beginning of the course using the Queens College Step Test to estimate cardiorespiratory fitness, the YMCA bench press test to assess muscular fitness, and 3-site skinfolds to estimate percent body fat. Height and weight were measured to calculate BMI. Data were analyzed using independent measures t-tests to evaluate differences between the 1999 and 2019 groups. Participants were also categorized as normal weight/overweight and obese/nonobese, and Pearson chi-square evaluated significant differences in those categories from 1999 to 2019.

RESULTS: Participants were significantly higher in percent fat (25.45 ± 0.72%) in 2019 than in 1999 (22.97 ± 0.71%; $p = 0.0149$). Performance on the YMCA bench press test decreased in 2019 (11.78 ± 9.48 reps) compared with the same test in 1999 (23.7 ± 9.37 reps; $p < 0.0001$). BMI was statistically the same from 1999 to 2019 (22.79 ±

0.43 kg/m² in 1999 vs. 22.90 ± 0.44 in 2019; p=0.86), as was estimated VO₂ max in ml/kg/min (35.72 ± 0.42 in 1999 vs. 36.20 ± 0.43 in 2019; p=0.4258). Although BMI was statistically the same during both years, the percent of students who were obese (BMI > 30) increased from 2 out of 72 (2.78%) in 1999 to 5 out of 69 (7.24%) in 2019. According to the Pearson chi-square test, this was not a significant difference in BMI classification (p=0.2682).

CONCLUSIONS: According to this study, college females have increased in percent body fat and decreased in muscular fitness in the past 20 years.

Cross-sectional And Longitudinal Relationships
Between Physical Fitness And Health Status Among
University Students

Yuichi Nakahara-Gondoh¹, Kenji Tsunoda², Takahiro Ikeda¹, Toshihiko Fujimoto³. ¹Fukuoka Prefectural University, Fukuoka, Japan. ²Yamaguchi Prefectural University, Yamaguchi, Japan. ³Tohoku University, Sendai, Japan.

(No relevant relationships reported)

Since physical fitness (PF) is based on past lifestyle that include physical activity (PA), current PF could reflect health status. Although previous studies have identified a positive relationship between health status and PA and among university students, the relationship with PF is unclear. **PURPOSE:** The present study aimed to determine whether the PF level of university students is related to health status independently of PA, by cross-sectional and one-year follow-up designs. **METHODS:** The study surveyed 245 freshman university students in April 2018 (immediately after university admission) and February 2019 (end of second semester). We examine PF by having the students complete physical fitness test were standardized by the Japanese Ministry of Education. Sleep sufficiency, happiness, and subjective health status were assessed using numeric rating scales from 0 to 10. Sleep duration and the CES-D were also assessed. We examined cross-sectional correlations by assessing partial correlations with adjustments for gender, PA (IPAQ-short), living arrangements, and economic status. Longitudinal data were assessed using two-way repeated ANCOVA with the above adjustments. Students were considered to have high, medium, and low (n = 61, 94, and 72, respectively) PF levels based on standardized scores derived from the physical performance tests. **RESULTS:** PF correlated with sleep sufficiency (partial r = 0.129), happiness (partial r = 0.180), and subjective health status (partial r = 0.247), independently of PA. Health indexes did not interact in the longitudinal design. However, a significant group effect was identified in sleep sufficiency, happiness, and subjective health status; students with higher PF were more likely to have to better health status than others during the followup period. The adjusted mean baseline and followup values for subjective health status remained significantly lower in the group with low PF than in the groups with medium and high PF (baseline: 5.9 vs. 6.7 and 7.3, respectively; followup: 5.1 vs. 6.2 and 6.9, respectively). **CONCLUSIONS:** University students with higher PF had better health status than others during a followup period. Maintaining higher PF could have positive health benefits for university students independently of PA. Supported by JSPS KAKENHI Grant Number 18K10931.

Long-term Participation In Four Different Sports
(Aerobics, Tai-chi, Track And Field And Diabolo): A
Comparison Of Fitness Measures

Peixuan Zheng¹, Mark Richardson¹, Hayley MacDonald¹, Lei Zhang², Feng Shi². ¹The University of Alabama, Tuscaloosa, AL. ²Zhengzhou University, Zhengzhou, China.

Email: pzhen2@crimson.ua.edu

(No relevant relationships reported)

It is well-known that long-term participation in sports is beneficial for physical fitness, especially for older adults. However, little is known about potential differences in fitness effects with long-term participation in different common sports.

Purpose: This study investigated the fitness effects of long-term participation in four popular sports (Aerobics, Tai-chi, Diabolo, and Track and Field) in middle-aged females.

Methods: One hundred and fifteen female subjects (aged 45-54 years old), who were selected to be National Sports Instructors (NSI) in China (2016 and 2017), participated in this study. All of them had been performing their specific sports specialty for at least nine years, which was also the basic requirement to become a NSI. Sports included Aerobics (N=30), Tai-chi (N=28), Diabolo (N=29), and Track and Field (N=28).

Measures included height, weight, body composition, waist-hip ratio, resting heart rate, blood pressure, vital capacity, grip strength, flexibility (sit and reach), reaction time, and balance (time on one-leg standing with eyes closed). Data were analyzed using one-way analysis of variance (ANOVA), and Fisher's LSD test was used for post hoc comparisons of significant differences.

Results: As shown in Table 1, vital capacity and flexibility were greater (*P<0.05) in the Aerobics group versus other groups. Lean body mass was greater in the Tai-chi group versus other groups (**P<0.05). No significant differences between groups existed for the other variables.

	Aerobics (N=30)	Tai-chi (N=28)	Diabolo (N=29)	Track and Field (N=28)
Vital capacity (mL)	3072.80± 659.77*	2645.77± 576.38	2483.35± 244.05	2957.46± 659.99
Flexibility (cm)	24.41± 8.72*	20.73± 8.25	16.93± 7.91	16.33± 7.24
Lean body mass (kg)	58.51± 7.06	61.87± 8.34**	61.06± 7.15	65.20± 6.43

Conclusions: Several different fitness outcomes differed by sports participation in female participants. Those participating in aerobics had the greatest vital capacity and flexibility, while those participating in Tai-chi had the greater lean body mass. Future research should continue to explore fitness outcomes in these sports. This is especially true for diabolo, in which there is limited research compared to the other sports.

2548 Board #9 May 29 9:30 AM - 11:00 AM
The Effects Of Aerobic And/Or Resistance Training On
The Sf-36 Health Survey From Stride-AT/RT

William C. Bennett¹, Katherine A. Collins¹, Cris A. Slentz¹, Lori A. Bateman¹, Leslie H. Willis¹, Lucy W. Piner¹, Kim M. Huffman¹, Joseph A. Houmar, FACSM², William E. Kraus, FACSM¹. ¹Duke Univ., Durham, NC. ²East Carolina University, Greenville, NC. (Sponsor: William E. Kraus, FACSM)

Email: william.bennett@duke.edu

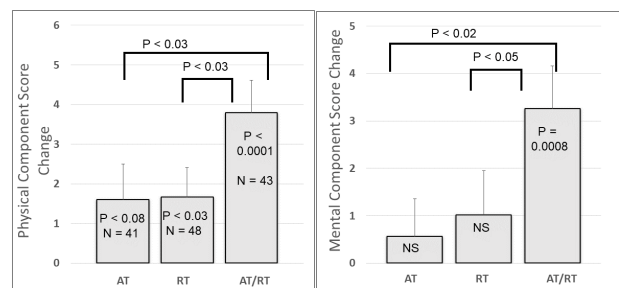

(No relevant relationships reported)

Purpose. While exercise has numerous health benefits, the optimal exercise mode is unknown. Many organizations recommend aerobic training (AT) and resistance training (RT), yet few studies have compared their effects alone or in combination. The purpose of this study, as part of the Studies Targeting Risk Reduction Interventions through Defined Exercise - AT/RT (STRIDE AT/RT), was to compare the effects of AT, RT and the combination of the complete AT and complete RT training programs on the Physical and Mental Component scores from the SF-36 Health Survey.

Methods. Subjects were 18-70 y, sedentary, overweight/obese with moderate dyslipidemia. Of those randomized, 74% or 155 subjects completed the 8-month intervention. A subset of participants (132) had complete SF-36 data pre and post training. The randomized training groups were: 1) Resistance Training (RT) (3 d/wk, 3 sets/day, 8-12 rep/set) for 8 RT exercises = 72 sets/wk (~ 135-160 min/wk), 2) Aerobic Training (AT), [equivalent to ~12 miles/wk at 65-80% peak VO₂], required an average of 133 min/wk, 3) Aerobic Training + Resistance Training (AT/RT = complete RT + complete AT).

Results. Figures show intervention effects on change in the Physical and Mental Component scores from the SF-36 questionnaire. The p-values inside each bar indicate significant within group changes. The bars with p-values connecting 2 groups show a significant difference between groups.

Summary. All exercise groups experienced significant improvements in Physical Component score. However, only the AT/RT group had a significant improvement in the Mental Component score. Further, the AT/RT group experienced significantly greater improvements in both component scores compared to the AT and RT alone groups. Finally, the AT/RT group appeared to have an additive response (i.e., AT/RT = AT + RT) for the Physical Component score; whereas, the improvement in the mental component score suggests a synergistic (greater than additive) response.

2549 Board #10 May 29 9:30 AM - 11:00 AM
Motivation Of Student Athletes: A Self Determination Theory Perspective

Rajmund Tomik, Magdalena Ardenska. *Academy of Physical Education, KATOWICE, Poland.*
 Email: r.tomik@awf.katowice.pl
 (No relevant relationships reported)

PURPOSE: To examine student athletes' motivation toward sport participation, and to compare male and female student athletes' motivation.
METHODS: The sample consisted of 290 athletes (167 males, 123 females), university students of sport and physical education. In order to assess student athletes' motivation, the Sport Motivation Scale (SMS) was used (Pelletier et al. 1995, 2012, 2013). The scale consists of 28 items assigned to seven subscales: amotivation, extrinsic motivation (external regulation, introjected regulation, identified regulation), and intrinsic motivation (to know, to accomplish and to experience stimulation). Descriptive statistics (means and standard deviations) were calculated. Cronbach's alpha was used to estimate reliability and internal consistency of the scales. In order to compare the mean values of the subscales (males and females), ANOVA with repeated measures was applied. The assumed significance level was set at $\alpha < .05$.
RESULTS: The Cronbach alpha values were high for all the subscales (SMS .87; AMS .90). Significant differences between males and females motivation toward sport participation were found for intrinsic motivation to accomplish (males $M=5.71$, $SD=1.20$; females $M=6.24$, $SD=.82$). There were no statistically significant differences in amotivation (males $M=2.32$, $SD=1.22$; females $M=2.08$, $SD=1.17$), external regulation (males $M=3.67$, $SD=1.50$; females $M=3.42$, $SD=1.48$), introjected regulation (males $M=5.48$, $SD=1.20$; females $M=5.29$, $SD=1.23$), identified regulation (males $M=4.90$, $SD=1.17$; females $M=5.13$, $SD=1.09$), intrinsic motivation to know (males $M=5.38$, $SD=1.29$; females $M=5.80$, $SD=1.00$), intrinsic motivation to experience stimulation (males $M=5.94$, $SD=1.02$; females $M=6.21$, $SD=.75$).
CONCLUSIONS: Results revealed that female student athletes' motivation toward sport participation showed higher levels of intrinsic motivation to accomplish than males. The mean values for amotivation subscale were significantly lower than for other subscales.

2550 Board #11 May 29 9:30 AM - 11:00 AM
Effects Of Exercise Training Alone Vs A Combined Exercise/Diet Intervention On The Sf-36 Health Survey
 Lorraine G. Elliott-Penry¹, Katherine A. Collins¹, Cris A. Slentz¹, Leslie H. Willis¹, Lori A. Bateman², Lucy W. Piner¹, Kim M. Huffman¹, William E. Kraus, FACSM¹. ¹Duke Univ., Durham, NC. ²Duke University, Durham, NC. (Sponsor: William E. Kraus, FACSM)
 (No relevant relationships reported)

Purpose. Although the Diabetes Prevention Program (DPP) established diet, exercise and weight loss as the 'gold standard' in preventive therapy for diabetes, the contribution of an exercise-only interventions on quality of life is not known. The purpose of this study, part of the Studies Targeting Risk Reduction Interventions through Defined Exercise - Prediabetes (STRIDE PD), was to compare the effects of different exercise groups vs DPP-like intervention on change in the Physical and Mental Component scores from the SF-36 Health Survey.
Methods. Subjects were healthy 45-75 y, sedentary, overweight/obese, with impaired fasting glucose, randomized as follows: 1) Low Amount/Moderate Intensity (L/M) - equivalent to exercising at 50% of VO_2 peak to expend 10 kcal per Kg of body wt per wk; 2) High Amount/Moderate Intensity (H/M) (16 kcal/kg/wk @ 50%); 3) High Amount/Vigorous Intensity (H/V) (16 kcal/kg/wk at 75% of VO_2 peak) and 4) Low Amt/Mod Intensity exercise + Diet/weight loss (L/M + D). The SF-36® Health Survey was administered pre and post intervention. This survey measures 8 domains of health, 4 combine to provide a Physical Component score and the other 4 combine for a Mental Component score.
Results. The figures below show the effects of each group on change in the Physical and Mental Component scores. The p-values inside each bar indicate significant within group changes. The lines with p-values above and connecting two groups show a significant difference between groups.
Summary. All intervention groups experienced highly significant improvements in the Physical Component score. However, only the Low/Mod/Diet group had a significant improvement in the Mental Component score. While these data need to be replicated, the clinical significance of these results suggest that many amounts/intensities of aerobic exercise training can improve self-rated physical function scores, and that exercise plus a weight loss diet improves mental and physical scores.

2551 Board #12 May 29 9:30 AM - 11:00 AM
Functional Movement And Subjective Well-being Assessments Of Female Track And Field Athletes: Pre- And Post-indoor Season

Lynn A. Darby, FACSM¹, Aliyah M. Gustafson¹, Bonnie G. Berger¹, David R. Owen². ¹Bowling Green State University, Bowling Green, OH. ²Brooklyn College of the City University of New York, Brooklyn, NY.
 Email: ldarby@bgsu.edu
 (No relevant relationships reported)

Track and Field (TF) is a sport that includes short- and long-distance running events and field events. Because of these diverse events, TF athletes employ a wide range of energy system demands and specific skills/techniques during performances.
PURPOSE: To evaluate functional movements and subjective well-being of NCAA Division I, TF female athletes when measured before and after a 7-week indoor season to identify the benefits and detriments of competing during an indoor season (January to March).
METHODS: Participants completed pre- and post-season measures: the Functional Movement Screen (FMS; Cook, 2010), the Y-Balance Test (YBT; Plisky et al., 2009), Physical Activity Enjoyment Scale-Trait (PACES-T; Kendzierski & DeCarlo, 1991), and the Satisfaction with Life Scale (SWLS; Diener et al., 1985). Athletes ($N=21$ completed all testing; 3 dropped out due to injury; Mean age \pm S.D., 20.0 ± 1.4 yrs) were grouped by event: throwers (shot put, weight throw), distance runners, and other competitors (sprinters, hurdlers, and jumpers). For all dependent variables, 3 (Group) by 2 (Time) ANOVAs and Pearson correlations were calculated.
RESULTS: Although there were no group differences, athletes' total FMS scores improved significantly pre- (14.8 ± 2.5) to post-season (15.6 ± 2.2 ; $p = .03$). Scores from each pre- to post-season FMS test were analyzed using Wilcoxon signed-rank tests. Scores for the Deep Squat ($p = .025$) and Right Shoulder Mobility ($p = .007$) improved significantly. However, scores for the Left Hurdle Step (hip flexion and extension; $p = .034$) decreased over the indoor season. The YBT posteromedial reach distance was significantly greater when pushing with the left leg ($p < .05$) perhaps reflecting the right-leg dominance for most athletes (83% were right leg dominant). The relatively high scores on PACES-T and SWLS did not change after the season (post-season: 102.5 ± 17.4 ; 27.1 ± 5.1 , respectively). PACES-T was related to SWLS both at pre-season ($r = .50$) and post-season ($r = .60$; $p < .01$).
CONCLUSIONS: In support of the physiological and psychological benefits of college TF participation, these Division I athletes improved their total FMS scores pre- to post-season. They also reported high exercise enjoyment and satisfaction with life scores despite participating in a demanding indoor, competitive season.

Relationships Among Motivation Type, Academic Achievement, And College Athlete Status

Reagan Elizabeth Moffit, Samantha J. Deere, Rebecca A. Schlaff, FACSM, Meghan Baruth. *Saginaw Valley State University, University Center, MI.* (Sponsor: Rebecca Schlaff, FACSM)
 Email: remoffit@svsu.edu
 (No relevant relationships reported)

Motivations to attend college differ between college athletes and non-athletes. Previous literature indicates a relationship between motivation type and college student GPA. However, the role of athlete status in this relationship has not been explored.
PURPOSE: To evaluate the differences in GPA 1) between student-athletes and non-athletes and 2) among motivation types to attend college. In addition, this study aimed to 3) investigate motivation to attend college as a moderating variable in the relationship between student-athlete status and GPA.
METHODS: Participants were recruited through a health-related college and athletic program at a NCAA

Division II Liberal Arts College in the Midwest and were asked to complete an online survey (n=209). Multiple demographic variables were assessed. In addition, students were asked to report athlete status (current athlete, yes/no), college cumulative GPA (4.0 scale), and to complete a modified version of the American Motivation Scale College Version (AMS-C). A primary motivation type was identified based on the AMS-C results. Motivation types with small sample sizes were combined together. Means, standard deviations, and percentages were calculated for all variables of interest. Independent samples t-test, ANOVA and ANCOVA were used to assess purposes 1, 2, and 3, respectively. **RESULTS:** The majority of students were freshmen (33.5%), female (75.1%), and white (90.4%). On average, students reported a college cumulative GPA of 3.42±0.43. Most students identified as extrinsically motivated (82%), 6% identified as intrinsically motivated, 12% identified as both, and no participants identified as amotivated. No differences were found in GPA between athletes (3.43±0.42) and non-athletes (3.41±0.44), p=0.70. No differences were found in GPA among motivation types, p=0.751. The interaction between motivation type and athlete status did not significantly relate to GPA (p=0.447). **CONCLUSION:** Athlete status and motivation type do not relate to self-reported college student GPA. Future research should investigate these relationships in a more heterogeneous sample. Further, it is important to continue to investigate extrinsic motivation in college students and its influence on academic success.

2553 Board #14 May 29 9:30 AM - 11:00 AM
Relationship Between Physical Activity Intensity And Bone Mineral Density In Premenopausal Women

Sicong Ren, Weimo Zhu, FACSM. *University of Illinois Urbana-Champaign, Champaign, IL.* (Sponsor: Prof. Weimo Zhu, FACSM)
 Email: sicongr2@illinois.edu
 (No relevant relationships reported)

Osteoporosis has become a global health problem. Mechanical loading during physical activity (PA) and exercise increases and maintains bone mass and strength. Quantitative PA measures are needed to identify the functional loading intensity that is beneficial for bone health.

PURPOSE: This study aimed to examine the relationship between PA intensity and bone mineral density (BMD) at the femur and spine in premenopausal women. **METHODS:** The data from 2005–2006 National Health and Nutrition Examination Survey (NHANES) were used for this study. PA was assessed using ActiGraph accelerometers, and bone health metrics were measured through dual-energy X-ray absorptiometry. After removing all missing values, 1446 female participants (Age: 47.61 ± 5.39 yr., Height: 162.01 ± 6.30 cm, Weight: 74.60 ± 16.80 kg, BMI: 28.45 ± 6.30 kg/m²) remained. PA intensity is translated from accelerometer counts per minute (cnts/min) using the thresholds in previous calibration studies, e.g.: Light intensity activity = 100–1951 cnts/min, Moderate–vigorous intensity = 1952–5724 cnts/min, and Vigorous intensity > 5724 cnts/min. The bone health metrics were the BMD of femur neck, trochanter, total femur, and total spine. The correlations between PA intensity with bone health metrics were computed. **RESULTS:** The means and standard deviations of Light intensity = 537.79 ± 85.59 (cnts/min), Moderate-vigorous intensity = 2694.48 ± 340.54 (cnts/min), and Vigorous intensity = 7120.53 ± 1721.06 (cnts/min). A low correlation between overall PA intensity and total BMD (r = 0.01) was found. Correlations between different PA intensities and BMD are summarized below:

Bone Mineral Density	Light Intensity	Moderate–vigorous Intensity	Vigorous Intensity
Femur neck	0.06	-0.07	0.02
Trochanter	0.10	-0.01	0.03
Total femur	0.09	-0.03	0.01
Total spine	0.03	-0.02	-0.09

CONCLUSION: Although low correlation was found between PA intensity and BMD, only no or low correlation was found between BMD and a specific PA intensity. Lack of variabilities within a specific PA intensity may be the reason. More studies are needed to understand the relationship between PA intensity and bone health.

2554 Board #15 May 29 9:30 AM - 11:00 AM
Pre-performance Motivational Music Enhances Force Output Parameters In Healthy Adults

Alexander Lesser, Eric Waldon, Feilin Hsiao, Courtney Jensen. *University of the Pacific, Stockton, CA.*
 Email: alesser1@bellsouth.net
 (No relevant relationships reported)

Music is integral to sport, and is commonly heard during intervals between play, such as a timeout in basketball or as a baseball batter approaches the plate. When competition resumes, music is typically ceased owing to potential distraction. The

ergogenic effect of music during physical performance is well established; the effect of listening prior to activity is not. **PURPOSE:** To test the effect of pre-participation music on force output. **METHODS:** 23 recreationally active adults (7 men, 16 women) between the ages of 18-50 with no history of lower leg injury completed dominant leg flexion and extension using a Cybex HUMAC NORM dynamometer. After a standardized familiarization protocol, subjects completed 3 trials separated by 3 minutes. The experimental conditions were: 1) no preparational music, 2) researcher-selected music, and 3) participant-selected music. The order of trials was randomized and listening conditions were constant: headphones were worn during the silent trial, and volume and duration were identical during music trials. Peak torque (PT) and time to achieve peak torque (TPT) were recorded. Mixed ANOVA with repeated measures tested the difference between preparational music conditions. **RESULTS:** Subjects were 26.7 ± 8.4 years old. Across all trials, PT was 86.0 ± 36.6 ft-lb for extension and 50.5 ± 21.7 ft-lb for flexion; TPT was 1.2 ± 0.7 sec for extension and 0.9 ± 0.6 sec for flexion. Repeated measures ANOVA with a Greenhouse-Geisser correction found a PT difference in the trials for flexion (F=5.077; p=0.016) and extension (F=4.020; p=0.036). In both movements, the highest PT was achieved with participant-selected music and the lowest during the non-music trial. For flexion, post hoc tests using the Bonferroni correction revealed participant-selected music to have significantly higher PT than the non-music trial (p=0.043) and a weak trend for higher PT than the administrator-collected trial (p=0.099). These relationships were less significant in extension. Although the same patterns were reflected in TPT, the differences failed to reach significance for flexion (p=0.125) and extension (p=0.420). **CONCLUSIONS:** These findings support the ergogenic effect of pre-participation music on post-listening performance, and the importance of administrator selection.

2555 Board #16 May 29 9:30 AM - 11:00 AM
Assessment Of Undergraduate Dancers' Health And Fitness Profiles At A Liberal Arts Public University

Marita K. Cardinal¹, Bradley J. Cardinal, FACSM². ¹Western Oregon University, Monmouth, OR. ²Oregon State University, Corvallis, OR. (Sponsor: Bradley J. Cardinal, FACSM)
 (No relevant relationships reported)

PURPOSE: ACSM is an affiliate of and contributor to “Athletes and the Arts” (A&A). A&A recognizes the demands and needs of performing artists and acknowledges their limited access to prevention and treatment services. Dance is one of the most grueling of the performing arts, particularly in terms of musculoskeletal injuries. This study’s purpose was to assess undergraduate dance students at a regional university in terms of their overall health and fitness profile to identify potential weaknesses that could be addressed through prevention focused efforts. **METHODS:** College dancers (N=22, M age = 19.8 ± 1.3; 18 female, 4 male) underwent a battery of 69 anthropometric, clinical, health, and fitness assessments. Clinical assessments were administered by licensed physical therapists, where all other data were collected and/or supervised by an “ACSM Certified Exercise Physiologist.” The analysis consisted of identifying primary weaknesses (i.e., those affecting >50% of the dancers) within the amalgamated areas. Due to space constraints, areas affecting <=50% of the dancers are minimally reported. **RESULTS:** Flexibility limitations were identified in the ankles (100%), hips (100%), and legs (86.4%), more than the knees (45.5%), x²(1) = 4.97, p=0.03. Weaknesses in strength were observed in the abdominals (90.9%), hips (77.3%), shoulders (77.3%), knees (63.6%), and ankles (54.5%), more than the feet (9.1%), x²(1) = 11.96, p<0.001. Postural misalignments were noticeable in the pelvis (100%), spine (95.5%), feet (77.3%), and shoulders (77.3%), more than the head/neck (50%) and knees (13.6%), x²(2) = 15.3, p<0.001. Specific concerns included weight distribution (100%), balance (90.9%), pelvic tilt (86.4%), iliac crest height (86.4%), shoulder height (86.4%), hamstring ROM (81.8%), thoracic curvature (81.8%), trapezius strength (72.7%), hip abductor strength (68.2%), scapula/shoulder placement (68.2%), knee flexor strength (63.6%), external hip rotator ROM (59.1%), ankle-foot alignment (59.1%), and lumbar curvature (54.5%). **CONCLUSION:** Dance technique classes are insufficient for addressing these problems and may even contribute to them. Dancer screens and individualized, supplemental conditioning and referral to medical professionals is needed. ACSM/A&A can support these efforts through advocacy.

2556 Board #17 May 29 9:30 AM - 11:00 AM
The Association Between Physical Activity Behaviors And Academic Performance In College Students

Mackenzie Rae O’Connell, Jennifer M. McKay, Lesley M. Scibora. *University of St. Thomas, SAINT PAUL, MN.*
 Email: ocon3943@stthomas.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to determine how sedentary and physical activity behaviors correlate with academic performance among undergraduate college students, implementing two objective measures and a subjective measure of physical activity.

METHODS: Fifty-one (22 males, 29 females) participants (age 20.2 ± 0.1 years) were instructed to simultaneously wear ActiGraph and ActivPAL monitors continuously,

24h each day for seven days. Sleep/non-wear time was excluded from analysis. Demographics data, including self-reported grade point average (GPA), and mean daily minutes of sedentary (sitting time), light, moderate, and vigorous intensity physical activity (PA) were collected. Participants also kept a 7-day self-reported physical activity log and completed the International Physical Activity Questionnaire (IPAQ) at the end of the seven days.

RESULTS: Females engaged in significantly higher mean daily minutes of moderate intensity activity than males (60.1 ± 25.4 vs. 47.3 ± 13.2 ; $p = 0.047$). Self-reported GPA for females was significantly greater than males (3.7 ± 0.3 vs. 3.4 ± 0.3 ; $p = 0.019$). For males, mean minutes of light intensity PA measured by ActivPAL and Actigraph was negatively correlated with GPA ($r = -0.448$ and $r = -0.491$, respectively; both $p < 0.05$). When considering self-reported PA by males, mean sitting time was positively correlated with GPA ($r = 0.702$; $p < 0.001$), but there was not association with GPA for females. For females, ActivPAL-measured light intensity PA was positively correlated with GPA ($r = 0.504$; $p < 0.05$).

CONCLUSIONS: Results of this study showed that female college students spent more time in moderate intensity PA than males. Further, for both objectively and subjectively measured PA behavior, more daily sitting was associated with a higher self-reported GPA in males, but the opposite was true for females. Interestingly, the more time male college students spent in light intensity the lower their GPA, but the opposite was true for females. These results suggest that physical activity behaviors have different relationships with academic performance in college males and females.

2557 Board #18 May 29 9:30 AM - 11:00 AM Detecting Swimming Strokes Using Pattern Recognition Analysis

Xiong Qin¹, Yadong Song², Guanqun Zhang², Fan Guo³, Weimo Zhu, FACSM¹. ¹University of Illinois at Urbana and Champaign, Urbana, IL. ²Lifesense, Shanghai, China. ³Southeast University, Nanjing, China. (Sponsor: Weimo Zhu, FACSM)
Email: xionq2@illinois.edu
(No relevant relationships reported)

PURPOSE: While exercises such as walking, running or cycling can be distinguished well by accelerometry, little was reported for swimming. Purpose of this study was to detect four common swimming strokes using a pattern recognition analysis and determine the swimming time of each stroke.

METHODS: A total of 17 swimming athletes (9 females, 53%) from the Southeast University, China were recruited and their age (M±SD, male: 20 ± 0.8 , female: 19.4 ± 1.0 , total: 19.7 ± 0.9 yr.), height (184.5 ± 3.2 , 172.1 ± 5.4 , 178.3 ± 7.7 cm), body weight (82.9 ± 6.0 , 61.3 ± 5.3 , 72.1 ± 12.4 kg), years of training on swimming (12.5 ± 1.8 , 12.9 ± 1.9 , 12.7 ± 1.8 yr.) were collected. Each participant performed breaststroke, front crawl, backstroke and butterfly in their own preferred orders four laps in a 50-meter pool, with an Actigraph GT9X inertia measurement unit on right or left wrist with their own preference. The middle two minutes recording of each stroke were extracted out and divided into 12 segments with 10 seconds each. Each segment was coded based on the stroke type. Two classifiers, linear discriminant analysis (LDA) and support vector machine (SVM), were used for the analysis. Random 13 people were selected into training data and the remaining 4 participants for cross validation. Swimming time of each stroke is the sum of time that recognised as certain stroke. The analysis was performed using R.

RESULTS: The accuracy of correct classification is 0.995 ± 0.012 by LDA and 0.984 ± 0.021 by SVM while corresponding cross-validation accuracy are 0.917 ± 0.085 and 0.964 ± 0.046 , respectively, with no statistical significant difference between male and female. As a result, SVM was used to further determine the sensitivity and specificity of the algorithm of each stroke and swimming time accuracy:

Sensitivity, Specificity and Time Accuracy				
	Breaststroke	Front Crawl	Backstroke	Butterfly
Sensitivity	0.985 ± 0.044	0.966 ± 0.066	0.971 ± 0.083	0.995 ± 0.020
Specificity	1.000 ± 0.000	0.961 ± 0.069	0.984 ± 0.051	0.982 ± 0.034
Accuracy of Time	98.5%	94.1%	95.1%	97.5%

CONCLUSIONS: With a wearable device and SVM like pattern recognise algorithm, swimming strokes can be accurately detected, which provides a great convenience to track the participation time of swimming activities.

2558 Board #19 May 29 9:30 AM - 11:00 AM Reactive Strength Index Scores Are Associated With Injury Risk And Game Performance In Female Collegiate Volleyball Players

Jason Brumitt, Robin Dorociak, Tyler Cuddeford. George Fox University, Newberg, OR.
Email: jbrumitt@georgefox.edu
(No relevant relationships reported)

PURPOSE: The reactive strength index (RSI) is a measure used by coaches to quantify an athlete's explosiveness. The RSI score is calculated based on one's drop vertical jump (DVJ) performance ($RSI = \text{jump height [m]} / \text{contact time [sec]}$). The purpose of this study was twofold. The first purpose of this study was to evaluate the ability of preseason RSI scores to discriminate injury risk in female collegiate volleyball (VB) players. The second purpose was to evaluate correlations between preseason RSI scores and game statistics. **METHODS:** 117 female collegiate VB players representing 3 levels of competition participated. Reflective markers were applied to the pelvis and the lower extremities. Athletes performed 3 DVJ from a 30.48 cm box. Subjects were instructed to drop off the box, land with one foot on each force plate (BP 600600 force plate, ATMI, Watertown, MA), and then immediately upon landing jump as high as possible. Reflective marker and force data was collected simultaneously with an 11 camera Qualisys motion system (Gothenburg, Sweden) at 100 Hz for the 3D marker data and 1000 Hz for the force plates. Visual3D (C-Motion, Germantown, Maryland) was used to create the kinematics and kinetics. A receiver operator characteristic curve was constructed to identify a cutoff score for subsequent risk analysis. Relative risk was calculated to determine the difference in injury risk between two groups based on cutoff score dichotomization. The Pearson product-moment correlation coefficient was calculated to determine the relationship between preseason RSI scores and game statistics. **RESULTS:** Mean preseason RSI scores were 0.88 m/s (± 0.31). Athletes with a lower preseason RSI score (0.9125 m/s or less) were 4 times more likely (relative risk = 4.4 [95% CI: 1.0, 18.4]; p -value = 0.022) to experience a noncontact time-loss injury to the low back or lower extremities during the season. There was a significant correlation between preseason RSI score and kills/set ($r = 0.369$; p -value = 0.000) and points/set ($r = 0.360$; p -value = 0.000). **CONCLUSIONS:** The RSI measure should be collected as part of a preseason screening clinic to identify female collegiate VB players at risk for a noncontact time-loss injury to the low back or lower extremities. The RSI score could also be used by VB coaches when evaluating current and future athletes.

2559 Board #20 May 29 9:30 AM - 11:00 AM Can Lower Body Instabilities Influence Shoulder Mobility And Predict Injury Risk In Collegiate Athletes?

Ben Resnick, Jessie Juenemann, Jennifer Dysterheft Robb. Hamline University, St. Paul, MN. (Sponsor: Lisa Stegall, FACSM)
Email: bresnick01@hamline.edu
(No relevant relationships reported)

PURPOSE: Throughout the NCAA, over half of the student-athlete population predominantly use their upper body for success in their sport. Unfortunately, these athletes are also highly prone to upper body injury. One possible explanation for this could be disturbances in the kinetic chain of movement. To examine the possible relationship between hip, knee, and ankle instabilities and shoulder mobility in upper-body dominant, collegiate athletes.

METHODS: A total of 26 UBAs were recruited from Hamline University and completed a series of tests. The tests that were administered were the Functional Movement Screen (FMS), a shoulder range of motion test, a vertical jump test, and sport-specific movement. These tests were recorded using a 3D motion capture system, comprising of 39 reflective markers and six infrared cameras. To examine the relationship between upper and lower-body measures, a correlational analysis was used to help reveal the strength of possible predictive relationships between specific lower body instability tests and upper body stability. Additionally, qualitative analysis was performed on movement recordings to identify abnormalities.

RESULTS: Quantitative results indicated strong relationships existed between the FMS Left Hurdle Test and FMS Right Shoulder Mobility (0.55 , $p = 0.004$), FMS Left Lunge Test and Rotator Cuff Internal Rotation (-0.52 , $p = 0.007$), and FMS Right Lunge and Rotator Cuff Ext. Rotation (-0.50 , $p = 0.009$). Additionally, qualitative results of the study suggest that participants who show instabilities may have some shoulder mobility issues demonstrated performing sport specific movements. **CONCLUSIONS:** The FMS may show that a lower body instability may result in heightened risk of injury in the upper body due to decreased range of motion and improper force transfers. The FMS was limited in information provided, therefore qualitative analysis may be more beneficial in predicting injury risk in UBA.

2560 Board #21 May 29 9:30 AM - 11:00 AM
Functional Movement Screen Scores And Injury Risk Factors In NCAA Division III Football Players
 Ana B. Freire Ribeiro. *Augsburg University, Minneapolis, MN.*
 (Sponsor: Mark Blegen, FACSM)
 Email: ribeiro@aughsburg.edu
 (No relevant relationships reported)

The functional movement screen (FMS) is used to identify asymmetries and imbalances in the body. It contains seven movement patterns rated on a 0 to 3 scale: deep squat (DS), hurdle step (HS), in-line lunge (ILL), shoulder mobility (SM), active straight leg raise (ASLR), trunk stability push up (TSPU), and rotary stability (RS) (Cook, 2006). In professional football players, FMS composite scores below 14 are associated with increased injury risk (Kiesel, 2007). In junior Australian players, the presence of two tests with asymmetries was indicative of injury risk (Chalmers, 2017). There are no established normative scores for NCAA Division III football players; furthermore, it is not known how many athletes display risk factors for injury. **PURPOSE:** To describe FMS scores and potential injury risk in NCAA Division III football players. **METHODS:** Fourteen current football players from an urban Midwestern University were recruited and consented to participate in this pilot study. Participants were assessed in the FMS by one certified level 1 tester, according to the procedures described by Cook et al. (2006). Scores below 14 and players with more than two asymmetrical scores were totaled.

RESULTS: The mean FMS composite score was 14.57 (SD=2.2). Three (21%) athletes had composite scores below 14. Two athletes (14%) had two or more asymmetries.

DISCUSSION: FMS composite scores were similar to the mean score of 14.1 described for healthy Division I athletes by Warren (2015), but below the mean of 16.9 for professional football players (Kiesel, 2007). Two of the athletes with scores below 14 had sustained previous knee injuries, but were fully rehabilitated at the time of the testing. One of these athletes also had a composite score below 14, suggesting that a history of previous injury places athletes at greater risk for re-injury. Athletic training and coaching staff should consider these factors when assessing return to play readiness in DIII football players.

CONCLUSIONS: FMS composite scores for DIII were similar to DI football players, but lower than professionals. Previous history of injury may impact the number of asymmetries displayed in the FMS, potentially resulting in higher re-injury risk.

Functional Movement Screen: Single Items For Injury Prediction Of Physical Education And Exercise Science Students.

Simone Schweda¹, Daniel Leyhr², Inga Krauss³. ¹Medical Clinic, University Hospital, Tuebingen, Germany. ²Eberhard Karls University, Tuebingen, Germany. ³Medical Clinic, University Hospital Tuebingen, Tuebingen, Germany.
 (No relevant relationships reported)

Screening tools for the individual risk of injury in athletes have gained high popularity lately. Not only professional athletes, but also college students are in need for cost efficient and quick screening tools to allow targeted injury prevention. The applicability of the Functional Movement Screen (FMS) as a valid screening tool for injury prediction among various populations has been evaluated in several studies. Most studies have drawn their conclusions from the composite score. Only a few studies have examined the validity of single items for injury prediction. In addition, gender differences have only been taken into account to a limited extent.

PURPOSE: The aim of the study was to determine the applicability of the FMS composite score and its seven single items for the sex-specific prediction of injury among German physical education and exercise science students. **METHODS:** Overall, $N = 99$ physical active college students (female: 53, male: 46) between 18-29 years of age were recruited. All participants performed a FMS at the beginning of two consecutive semesters. All injuries were recorded monthly for the entire semester. Receiver operating characteristic (ROC) curves and area under the curve (AUC) were used to estimate an optimal cut-off score for females and males separately and to assess the ability of the FMS sum score to predict an injury. Logistic regression analysis was utilized to assess odds ratios for the chance of injury related to single items of the FMS. **RESULTS:** The ROC curves indicated moderate ability in the injury prediction for women (AUC: 0.66, $p = 0.02$) and poor injury prediction for men (AUC: 0.40, $p = 0.19$). However no satisfying cut-off score could be determined for any gender due to poor sensitivity and specificity. The logistic regressions revealed the Deep Squat (DS) to be significant for women ($p = 0.03$, OR= 0.2). **Conclusion:** The FMS is frequently cited as a useful screening tool for subsequent injury. In this regard, cut-off values are used to identify persons at high risk for injury. The DS was the only significant single item for women in this study, but had no strong prediction effect. Results of this study cannot provide solid gender-specific recommendations for the use of the FMS composite score or single items as an injury screening tool for German physical education and sports science students.

2562 Board #23 May 29 9:30 AM - 11:00 AM
Frontal Plane Knee Biomechanics And Functional Movement Screen Scores Of Previously Injured DIII Football Players
 Christopher Aaron-Lee Calland. *Augsburg University, Minneapolis, MN.* (Sponsor: Dr. Mark Blegen, FACSM)
 Email: callandc@aughsburg.edu
 (No relevant relationships reported)

Football has the highest rate of knee injuries when compared to other contact sports (Rothenberg, 2016). It is important to investigate whether the risk for such injuries in NCAA Division III football players can be assessed by the Functional Movement Screen (FMS) and frontal plane knee alignment during a single leg squat (SLS), as suggested by Kiesel et al (2007) and Ugalde (2015), respectively.

PURPOSE: To compare FMS deep squat (DS) and active straight leg raise (ASLR) scores and to determine the relationship between frontal plane knee biomechanics in the SLS and ASLR and DS scores in healthy NCAA Division III football players and athletes with previous knee injuries.

METHODS: Fourteen football players (mean age = 21.4) were recruited and consented to participate in this study. They completed the FMS and were rated by a certified level 1 FMS tester, then changed into black compression clothing. Markers were placed on the tibial tuberosity and distal tibia to define absolute valgus and varus angles at the deepest point of the SLS, where the supporting heel was still in contact with the ground. Trials were recorded using a digital camera facing the frontal plane and angles were measured using Dartfish Software.

RESULTS: For the previously injured group ($n=7$), mean right SLS angle was 0.5° (valgus) and mean left SLS angle was 0.38° (varus), mean DS was 1.86, mean ASLR was 2.43, and mean composite score was 14.14. DS was negatively correlated with right ($r = -0.13$) and left ($r = -0.12$) SLS angles, right ASLR was negatively associated with right SLS ($r = -0.12$), left ASLR was negatively correlated to left SLS ($r = -0.13$). For the non-injured group ($n=7$), right SLS mean angle was 3.55° (valgus) and left mean SLS was 2.27° (valgus), mean DS was 2, mean ASLR was 2.43, and mean composite score was 15. DS was positively correlated with right ($r = 0.59$) and left ($r = 0.86$) SLS angles, right ASLR was negatively associated with right SLS ($r = -0.13$), left ASLR was negatively correlated to left SLS ($r = -0.66$). There was no significant difference in SLS angles, DS, or ASLR scores between groups ($p > 0.05$).

CONCLUSION: Knee angles in the SLS, DS, and ASLR scores did not differ between groups. For the healthy group, DS had strong positive relationships with SLS angles and left ASLR had a moderate negative relationship to left SLS angles.

2563 Board #24 May 29 9:30 AM - 11:00 AM
Does Baseline Performance On Return-to-Sport Tests Differ Amongst Injured And Uninjured NCAA Division 1 Athletes
 Hanna Clay, Suzanne Hoskinson, Melissa Marazzi, Takudzwa A. Madzima, Svetlana Nepocatyeh, Srikant Vallabhajosula, Shefali Christopher. *Elon University, Elon, NC.* (Sponsor: Stephen Bailey, FACSM)
 Email: hclay@elon.edu
 (No relevant relationships reported)

One of the most well established risk factors for future injury in athletes is having sustained a previous injury. Currently there is a lack of research regarding baseline performance of athletes on the common return to sport tests. Research evaluating baseline performance can expose the need of implementing an anticipatory rehabilitation program to avoid the risk of future injury.

PURPOSE: To investigate the differences in performance on a battery of tests amongst incoming collegiate athletes who have sustained a lower extremity injury in the past 6 months and those who have not.

METHODS: 40 (Males: 19 Females: 21) incoming collegiate athletes from an NCAA Division I University completed a battery of baseline tests that assessed their strength, flexibility, dynamic balance, power and speed. Individuals were categorized as injured and uninjured, with injury defined as having a lower extremity injury in the past 6 months (Injured: 16 Uninjured: 24).

RESULTS: The left knee flexion strength for injured (.32 \bar{F} .12/BW) was significantly greater than that of uninjured (.25 \bar{F} .1/BW; $p = .041$). The right hip internal rotation strength for injured (.20 \bar{F} .07/BW) was significantly greater than that of uninjured (.15 \bar{F} .06/BW; $p = .014$). The left hip strength was also significantly greater in injured (.20 \bar{F} .05/BW) compared to uninjured (.15 \bar{F} .06/BW; $p = .004$). For balance, the posterolateral reach from the Y-Balance test indicated a significant difference with uninjured (7.58 \bar{F} 6.38 cm) having a greater limb asymmetry compared to injured (3.49 \bar{F} 3.26 cm; $p = .03$). The flexibility, power and speed tests did not identify any differences.

CONCLUSIONS: The results indicated that athletes who were injured performed better on isometric strength tests and Y-Balance than those with no recent injuries. One potential hypothesis to account for these differences is that the injured athletes could have participated in an individualized rehabilitation program after injury to

address their functional deficits, which improved performance. Therefore, this study shows that it could be critical to screen all athletes, whether injured or uninjured, prior to participation in the athletic season.

Does Lower Extremity ROM Asymmetry Or Previous Injury Predict Weight Shift During The FMS Squat?

Eric P. Scibek, Matthew F. Moran, Mary C. Hemmer, Louis R. Castro. *Sacred Heart University, Fairfield, CT.*

Email: scibeke@sacredheart.edu

(No relevant relationships reported)

The Functional Movement Screen (FMS) Deep Squat Test (DS) assesses bilateral mobility of the ankle, knee and hip through a movement pattern that is intended to be performed with bilateral symmetry. Past history of lower extremity (LE) injury may influence LE joint range of motion (ROM). Previous studies have examined the influence of LE ROM on squat depth, but not its influence on lateral weight shift (LWS). **PURPOSE:** The purpose of this study was to determine if bilateral asymmetry in ankle, knee, and hip ROM or previous history of LE injury predicts LWS during the FMS DS. **METHODS:** Thirty-seven physically active subjects (19 F, 18 M, 20.8 ± 1.4 yrs) completed this IRB approved study. All subjects granted informed consent and completed a health history questionnaire including history of LE orthopedic injury. Subjects' hip flexion (HF), knee flexion (KF), and ankle dorsiflexion (DF) ROM were measured with a goniometer using standard methodologies. A loaded lunge (LL) measurement was also taken to determine peak closed chain dorsiflexion. ROM asymmetry was calculated for each measurement. Participants then completed three trials of the FMS DS on 2 force plates (1200 Hz) and a Matlab script processed vertical ground reaction force (vGRF) data with a lowpass filter and computed limb symmetry index during the descent phase and full squat position. Multiple regression models were computed for both the descent phase and the full squat position of the DS to determine if ankle, knee, and hip ROM asymmetry, LL asymmetry, and LE injury history are predictors of LWS during the DS. **RESULTS:** Mean ROM asymmetries for HF (-0.09% ± 3.37), KF (0.24% ± 1.8), DF (-5.30% ± 43.28) and LL (5.14% ± 8.93) were calculated. The overall regression model for the descent phase was not significant, ($F(5, 31) = 0.47, p = 0.796, r^2 = 0.07$) for the prediction of LWS. Additionally, the overall regression model for the full squat position was also not significant ($F(5, 31) = 1.67, p = 0.17, r^2 = 0.21$) for the prediction of LWS. **CONCLUSION:** Asymmetry in HF, KF, and DF ROM along with LL asymmetry and previous history of LE injury do not predict LWS during FMS DS performance. Further investigation is needed to identify the causes of asymmetric DS performance to aid clinicians in corrective exercise prescription.

Electromyography Assessments: Traditional Versus Non-Traditional Shoulder-Related Pre-/Rehabilitative Exercises

Michel Heijnen, Alexander McDaniel, Jennifer Carovillano, Alison Fitch, Ross Gillan, Mallory Gruender, Chelsea Houser, Pearl Lospinuso, Brittany Matsinger, Peter Murray, Benjamin Whitty, Wayland Tseh. *University of North Carolina Wilmington, Wilmington, NC.* (Sponsor: Athanasios Jamurtas, FACSM)

Email: heijnenm@uncw.edu

(No relevant relationships reported)

PURPOSE: To investigate the electromyographic difference between traditional versus non-traditional shoulder-related pre-/rehabilitative exercises. **METHODS:** Eighteen participants (Age = 22.2 ± 3.7 yrs; Height = 183.0 ± 6.9 cm; Body Mass = 84.5 ± 12.7 kg; Body Fat = 13.6 ± 5.7%) with no history of shoulder-related injuries performed three traditional (T) free weight and three non-traditional (NT) pre-/rehabilitative exercises, specifically, A, Y, and pushup plus (PU+). Surface dwelling electromyography electrodes were placed parallel to the fiber orientation on the belly of the mid-deltoid, mid-latissimus dorsi, pectoralis major, and upper trapezius. Root mean square (RMS) muscle activation was calculated for each of the exercises.

RESULTS: Table 1. Root mean square (mean ± SE) measured in μV between traditional and non-traditional A, Y, and pushup plus.

	Mid-Deltoid	Mid-Latissimus Dorsi	Pectoralis Major	Upper Trapezius
T A	246.9±31.6	180.6±25.7	109.6±27.2	129.5±19.9
NT A	192.1±32.8	161.2±26.1	79.3±27.3	167.0±20.1
T PU+	278.8±23.0*	133.4±56.6	213.6±25.8*	185.8±36.6
NT PU+	208.8±30.9	71.0±9.8	109.8±16.9	163.1±28.7
T Y	324.4±41.9	60.2±6.0	142.4±14.2	405.4±48.7
NT Y	346.2±46.4	73.1±15.0	159.5±28.7	585.5±66.8*

* $p \leq 0.05$

CONCLUSIONS: Neuromuscular activity between traditional and non-traditional A and Y exercises were relatively similar, thus supporting the notion that non-traditional shoulder-related pre-/rehabilitative exercises is a comparable method to supplement shoulder-related issues. Traditional pushup plus, however, evoked greater neuromuscular activity amongst two of the four targeted muscle groups, which may be explained due to the angular differences from the pivot point. From an applied perspective, therefore, practitioners and clinicians may utilize the non-traditional A and Y as another pre-/rehabilitative modality for shoulder-girdle augmentation.

The Impact Of Fatiguing, Intermittent Isometric Contractions On Muscle Force Variability

Tyler W.D. Muddle¹, Ryan J. Colquhoun², Nile F. Banks¹, Emily M. Rogers¹, Hannah F. Bryan¹, Nathaniel D.M. Jenkins¹.

¹Oklahoma State University, Stillwater, OK. ²University of South Alabama, Mobile, AL.

(No relevant relationships reported)

PURPOSE: To evaluate the influence of fatigue on force variability of the vastus lateralis (VL) during repeated isometric exercise performed at 30% maximal voluntary isometric contraction force (MVIC). **METHODS:** Twelve resistance-trained males (23.8 ± 3.6 y; 87.3 ± 10.5 kg; 176.3 ± 6 cm) completed MVIC testing and then repeated isometric contractions at 30% MVIC while tracking target force trajectories repetitively until they could no longer achieve 95% target force. Force and surface electromyographic (EMG) signals from the VL were collected during exercise. One-way repeated measures ANOVAs were used to analyze average force (F_{AVG}), coefficient of variation of force (F_{CV}), EMG amplitude (EMG_{RMS}), and median power frequency (MDF) during every 25% of the repetitions (REP) completed. To examine the relationship between EMG_{RMS} and F_{CV} across the work bout, F_{CV} was plotted against EMG_{RMS} , linear regression lines were fit, and correlation coefficients were calculated for each subject. **RESULTS:** No main effect of REP was observed for F_{AVG} ($p = 0.07$) or MDF ($p = 0.29$), but there was for F_{CV} and EMG_{RMS} ($p < 0.0001$). F_{CV} increased from the first to the 50-100% REP ($p \leq 0.001-0.02$), 25% to the 100% REP ($p < 0.001$), and the 50% to the 100% REP ($p < 0.001$). EMG_{RMS} increased from the first to the 25-100% REP ($p = 0.002-0.024$), the 25% to the 50-100% REP ($p = 0.001-0.019$), the 50% to the 75-100% REP ($p = 0.002-0.018$) and the 75% to the 100% REP ($p = 0.014$). Additionally, all 12 subjects displayed strong, significant, positive relationships for F_{CV} vs. EMG_{RMS} across the exercise bout (Table 1). **CONCLUSIONS:** The increase in both F_{CV} and EMG_{RMS} suggest that as fatigue develops during intermittent isometric exercise, force steadiness decreases while EMG amplitude increases. It is possible that the decrease in force steadiness occurred due to increased common synaptic input to the motor neuron pool secondary to fatigue-induced increases in net excitatory input.

2567 Board #28 May 29 9:30 AM - 11:00 AM

Does A Relationship Exist Between Range Of Motion And Proprioception Of The Ankle In Athletes

Hannah Elizabeth Fox¹, Andrew Shim¹, Michael Waller², Maureen Hoppe¹. ¹College of Saint Mary, Omaha, NE. ²Arkansas Tech University, Russellville, AR.
Email: hfox0592@csm.edu

(No relevant relationships reported)

Prevention and rehabilitation methods for ankle and Anterior Cruciate Ligament (ACL) injuries now include proprioception and Range of Motion (ROM) exercises as they are proven to be successful techniques. The purpose of this study is to determine if a relationship between lower extremity proprioceptive scores and ankle ROM in uninjured female collegiate soccer athletes exist. **PURPOSE:** To investigate a comparison between proprioception scores and Range of Motion (ROM) scores of the ankle in female collegiate soccer athletes to determine if a relationship exists. **METHODS:** A one shot case study design was used to determine if a relationship exists between proprioception scores and range of motion in female collegiate soccer athletes. Proprioception was tested using the Bertec Balance Posturography Plate measuring Center of Pressure (COP) on a normal surface (NS) and perturbed surface (PS) with eyes open (EO) and eyes closed (EC) as well as measuring Limit of Stability (LOS) with eyes open. The Goniometer was used to measure Inversion and Eversion in both the left ankle (LA) and right ankle (RA) joint. **RESULTS:** There were no significant relationship between proprioception and ROM in the ankle documented either in Inversion or Eversion. Statistical analysis indicated inversion of the left ankle resulted in diminished proprioception scores in both a normal surface with eyes open and perturbed surface eyes open compared to both surfaces with eyes closed, (LA NS-EO $p=0.105$, LA NS-EC $p=0.84$, LA PS-EO $p=0.225$, LA PS-EC $p=0.094$). There were no relationships between the variables due to the correlation coefficient resulting close to zero. (NS-EO: LA inversion $r=0.011$, LA eversion $r=0.060$, RA inversion $r=0.030$, RA eversion $r=0.006$) (NS-EC: LA inversion $r=0.175$, LA eversion $r=0.019$, RA inversion $r=0.003$, RA eversion $r=0.131$) (PS-EO: LA inversion $r=0.091$, LA eversion $r=0.017$, RA inversion $r=0.315$, RA eversion $r=0.040$) (PR-EC: LA inversion $r=0.165$, LA eversion $r=0.033$, RA inversion $r=1.556$, RA eversion $r=0.026$). **CONCLUSION:** These results suggest that no significant relationship exists between ankle joint ROM and proprioception scores. Further studies examining healthy uninjured ankle ROM in athletes should be conducted in order to identify relationships that could prevent ankle injuries from occurring.

2568 Board #29 May 29 9:30 AM - 11:00 AM

Relationship Between Dietary Calcium Intake And Muscle Performance In College Aged Adults

Dale Rogers, Cassidy Champoux, Andrew Weaver, Amir Bhochhibhoya, Pragma Sharma Ghimire. LANDER UNIVERSITY, Greenwood, SC.
Email: dale.rogers@lander.edu

(No relevant relationships reported)

It has been well established that several minerals such as calcium, potassium, and iron play an important role in muscle metabolism, muscle function, and physical performance. Although the importance of calcium has been well studied in bone metabolism, there is still a wide research gap in understanding the relationship between calcium intake and muscle performance, especially in young adults. **PURPOSE:** The purpose of this study is to investigate the relationship between dietary calcium intake and muscle performance in college-aged students. **METHODS:** This was a non-randomized cross-sectional study participated by 70 college-aged students. The dietary calcium intake questionnaire was used to estimate the amount of calcium consumed daily based on the content of the specific foods and was derived from a validated and quantitative food frequency questionnaire. The participant's lower and upper body strength was assessed by a vertical jump test (Just Jump Mat, Tendo Sports Machine), and handgrip test (Takei, Japan), respectively. **RESULTS:** The average calcium intake was found to be 1098 mg/day. A statistically significant positive relationship was observed between jump velocity ($r=0.31$; $p<0.01$), and relative power ($r=0.35$; $p<0.01$) with calcium intake. However, there were no significant relationships between calcium intake with jump height, time in air, and upper body muscular strength ($p>0.05$). **CONCLUSIONS:** Although the result suggests calcium intake was related to lower body muscle performance, in future experimental study should explore and control confounding variables to understand role of calcium intake on muscle performance in larger samples and in different sports.

Table 1. Participant's physical and muscle performance characteristics (n=70)

Variables	Mean \pm SE
Age (yrs)	20.81 \pm 0.19
Height (cm)	173.59 \pm 1.23
Weight (kg)	79.88 \pm 2.01
BMI (kg/m ²)	26.43 \pm 0.52
Dietary Calcium Intake	1098.09 \pm 72.05
Jump Height (inches)	20.72 \pm 0.62
Time in Air (sec)	0.64 \pm 0.01
Velocity (m/s)	1.34 \pm 0.02
Power (watts)	1058.26 \pm 36.18
Relative Power (watts/kg)	13.10 \pm 0.20
Right Hand Grip Strength (kg)	52.73 \pm 2.52
Left Hand Grip Strength (kg)	48.22 \pm 2.26

Comparing Bilateral Muscular Imbalance Ratios In The Upper Extremities

Zunen Acosta, Alexia E. Amo, Jacob M. Cunha, Ryan W. Jeremic, J. Mark VanNess, Courtney D. Jensen. University of the Pacific, Stockton, CA.

(No relevant relationships reported)

Muscular imbalances may increase the risk of injury and decrease physical performance. Conventional wisdom suggests dominant side musculature may be more developed owing to preferred usage. Quantifying muscle imbalance between non-dominant and dominant arms is facilitated by technology that permits the measurement of arm power output across a range of resistances. **PURPOSE:** To compare power output achieved by the dominant and non-dominant arms under various load conditions. **METHODS:** 18 females and 14 males (21.0 \pm 2.3 years, 66.9 \pm 4.3 inches, 168.3 \pm 36.2 lbs) were enrolled into an optimal muscle loading program using Proteus (Proteus Motion, USA). Each subject performed the following ten movements: abduction, adduction, external rotation, internal rotation, biceps curl, triceps extension, horizontal push, horizontal row, vertical push, and vertical row. Each movement was repeated twice under four separate loads: 7lb, 14lb, 21lb, and 28lb. Maximum average power for each movement was recorded in watts for further analysis. A paired-samples t-test, under the 28lb condition, was used to determine the relationship between the mean power of all subjects' dominant versus non-dominant arms. Repeated measures ANOVA was run to then determine differences in mean powers. **RESULTS:** Power achieved in all movements was similar (r values ranged from 0.723-0.954; $p<0.001$) at the 28 lb load. On average, an individual's dominant arm during abduction produced less power than the non-dominant arm (143.6 \pm 63.5 watts compared to 127.7 \pm 50.2; $p=0.050$). However, external rotation of the dominant arm tended to generate more than non-dominant arms ($p=0.053$). Correlation values close to 1.00 across all comparisons demonstrated the variance between arms was minimal. The results of the ANOVA showed no statistical differences between arms. **CONCLUSIONS:** The current assumption that dominant limbs are capable of greater power may not be true in all planes and when tested with isotonic loads applied in three-dimensional space. Our subjects did not demonstrate power imbalances between dominant and non-dominant arms.

The Effectiveness Of An Augmented Musculoskeletal Feedback System Compared To Traditional Core Stabilization Exercises

Craig Triplett, Nathan T. Deichert, Michelle Triplett, Vicki Burshia, Abbie Fredrick, Molly Graesser, Jacob Iverson, Cortez Standing Bear, Isaac Taylor. Black Hills State University, Spearfish, SD. (Sponsor: Matt Vukovich, FACSM)
Email: craig.triplett@bhsu.edu

(No relevant relationships reported)

PURPOSE: A prevailing health problem is low back pain (LBP). A common clinical strategy to treat LBP is the strengthening of key core stabilization muscles, the transverse abdominis (TrA) and lumbar multifidus (LM). The purpose of this study was to compare the effectiveness of using an augmented biofeedback device

versus traditional core stabilization exercises at strengthening the TrA and LM in healthy participants. **METHODS:** University students (41 females, 13 males), ages 18-25 years with no recent history of back injury and no history of back surgery were recruited. Participants were tested on the maximum voluntary contraction (MVC) of the TrA and LM at lumbar vertebrae levels L4 and L5 using wireless electromyography (EMG). Participants were split into two groups. The control group performed traditional core stabilization exercises, the experimental group used an augmented biofeedback device. Participants performed the exercises 3 times a week for 20 minutes. Participants returned after 8 weeks to retest the MVC. **RESULTS:** Paired-sample t-tests revealed significant improvements for Left L4 ($t(52) = 2.08, p < .05$), Left L5 ($t(52) = 2.14, p < .05$), Right L4 ($t(52) = 2.34, p < .05$), and Right L5 ($t(52) = 2.41, p < .05$) over the course of the 8-week exercise period. To determine if improvements differed across exercise conditions, a series of analyses of covariance (ANCOVA) were used. In all analyses, change scores were entered as the dependent variable with pre-test MVC entered as covariates. Exercise condition was entered as the independent variable. Results of the analyses revealed no significant effect of exercise condition on change score for Left L4 ($F(1,51) = .47, p = .50$), Left L5 ($F(1,51) = 1.72, p = .20$), Right L4 ($F(1,51) = .01, p = .95$), Right L5 ($F(1,51) = .18, p = .68$), Left TrA ($F(1,51) = .03, p = .86$), or Right TrA ($F(1,51) = .00, p = .95$). **CONCLUSION:** Results of the study found that MVC of the LM significantly improved in both groups. MVC of the TrA improved in both groups as well, however changes did not reach statistical significance. An augmented biofeedback device could be used as an alternative to traditional core stabilization exercises to strengthen the TrA and LM.

COMPARISON OF MUSCLE ACTIVATION BETWEEN THE CONVENTIONAL, SUMO AND STIFF-LEG DEADLIFT
 Dominique Vitanza. *California State University, Long Beach, Long Beach, CA.*
(No relevant relationships reported)

Purpose

The purpose of this study was to compare differences in muscle activation of the primary agonist muscles during three variations of deadlift - sumo (SDL), stiff-leg (SLDL), and conventional (DL) - in both men and women.

Methods

Twelve recreationally trained subjects (six males, six females; age: 23 ± 0.5 years, height: 182 ± 3.2 cm, body mass: 74 ± 6.1 kg, DL 1-RM: 128 ± 53.6 kg, SDL 1-RM: 127 ± 56.8 kg, SLDL 1-RM: 117 ± 49.6 kg) participated in this within-subject crossover design. Electromyographic (EMG), activity of the DL, SDL, and SLDL for the vastus lateralis (VL), vastus medialis (VM), biceps femoris (BF), medial hamstring group (MH), and erector spinae (ES) was measured. Gender differences were evaluated, comparing the difference in the H:Q ratio between male and female. For the second session, participants completed three repetitions at 80% of their 1RM for each lift as EMG data was collected. Raw EMG data was smoothed and rectified with NORAXON software (150 Hz) and mean peak activation was expressed as the root mean square (RMS). EMG values obtained during the 3 repetition experimental session were averaged then normalized to the EMG values achieved in the 1RM.

Results

Results showed no significant differences ($p > 0.05$) in normalized EMG values between the five measured muscles during the DL, SDL and SLDL. No significant difference ($p > 0.05$) was found in HQ ratios between males to females; however, there was a statistical trend in the SLDL that indicated sex differences in the HQ ratio, with males having the higher HQ ratio ($p = 0.063$).

Conclusions

This study revealed that no variation is superior in activating the quadriceps, hamstrings, or low back, indicating all three variations are acceptable methods to train the aforementioned musculature. Moreover, the lack of significant disparity between males and females suggests women are not quadriceps-dominant and display similar activation patterns to males.

The Effect Of Concentric Prime Movers Vs. Synergist Muscle Contraction On Coactivation Ratios
 Bulent Sokmen, Ryann DeSousa, German Reyes, Jose Limas, Nicholas Nygaard, Yazmin Moreno, Jireh Pejana, Emily Campbell. *Sonoma State University, Santa Rosa, CA.*
 Email: sokmen@sonoma.edu
(No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the coactivation ratio of agonist to antagonist muscle groups with varying pre-exhaustion protocols, and to see if postactivation potentiation is influenced by pre-exhaustion.

METHODS: Eight college age males and females were recruited for the study. Each participant visited the Human Performance Laboratory four times over the duration

of the study. Subjects were monitored via EMG and randomly performed 1 set of 50 repetitions maximal voluntary knee extension, knee flexion, and knee extension/flexion at $60^\circ \cdot s^{-1}$ using an isokinetic machine on the dominant leg. They performed 1 set of 10 repetitions of modified Peterson step-up testing at pre-exercise, immediately post-exercise, and seven (7) min following exercise.

RESULTS: The 50 repetitions of isokinetic knee extension, flexion, extension/flexion at $60^\circ \cdot s^{-1}$ resulted in a significant drop in peak torque in all groups ($P < 0.01$). Pre-exhausting the agonist muscle group prior to Pearson step-up improved agonist skeletal muscle motor unit recruitment ($P < 0.05$). Pre-exhausting the antagonist muscle group with flexion and combination prior to Pearson step-up did not have any effect on agonist skeletal muscle motor unit recruitment. Pre-exhausting the agonist muscle group down-regulated antagonist muscle activity. Coactivation improved only by fatiguing the agonist muscle group. Postactivation potentiation was only affected by fatiguing the agonist muscle group ($P < 0.05$).

CONCLUSIONS: We conclude that pre-exhausting the agonist muscle group might be beneficial for improving muscle activity in functional rehabilitation exercises and during the period of recovery. Given the small number of subjects in this study, additional research using larger subject groups and different fatiguing and post-activation protocols is warranted to support the use of pre-exhaustion techniques to improve activity/recruitment of atrophied muscle in physical therapy settings.

Electromyographic Analysis Of Steel Mace Exercises: A Descriptive Study Of Alternative Training Modalities
 Christian V. Ison¹, Lee E. Brown, FACSM², Vincent C. Kreipke¹, Gabriela Juache¹, Jennifer Rivera¹, Matthew R. Rodriguez², Edward Jo¹. ¹California State Polytechnic University, Pomona, Pomona, CA. ²California State University, Fullerton, Fullerton, CA. (Sponsor: Lee Brown, FACSM)
 Email: christian.v.ison@gmail.com
(No relevant relationships reported)

Alternative training modalities (ATM) have recently gained popularity as a form of resistance exercise through non-traditional methods and equipment. ATM share a common characteristic, the incorporation of non-traditional exercise movements and equipment in efforts to develop strength in a multi-planar fashion. Forms of common ATM include kettlebells, battle ropes, tires, and the steel mace. The steel mace, like a sledgehammer, consists of a long-levered club attached with a heavy sphere (i.e. mace head) fixed at one end. What remains relatively unknown are the neuromuscular demands of specific muscles or muscle groups among steel mace exercises. **PURPOSE:** To examine the electromyographic profile of four common steel mace exercises: the overhead squat, 360° overhead rotation, reverse lunge offset, and lap offset squat. **METHODS:** Twenty-nine resistance-trained males ($n=15$) and females ($n=14$) were recruited to participate in this cross-over experimental design investigation. All participants completed each of the four exercises with the mace head (i.e. heavy sphere) on both dominant and non-dominant sides of the body. Normalized surface electromyography (EMG) of the dominant-side upper trapezius, anterior deltoid, pectoralis major, triceps brachii, biceps brachii, external oblique, rectus femoris, and biceps femoris were analyzed. A one-way ANOVA was used to compare normalized EMG among muscles within each exercise and among exercises for each muscle. **RESULTS:** As a summary of major findings, for each exercise and muscle group, EMG activity was significantly altered when positioning the mace head ipsilateral vs. contralateral to the dominant side ($p < 0.05$). Additionally, each exercise demonstrated differential EMG activities among muscle groups ($p < 0.05$). Overall, the upper trapezius and rectus femoris exhibited the greatest EMG activity ($p < 0.05$). All muscle groups except for the biceps brachii and external oblique showed differential EMG activity among exercises ($p < 0.05$). **CONCLUSIONS:** The present findings provide practically significant information regarding the muscle-specific demands of popular steel mace exercises which may provide valuable insight for athletes, fitness enthusiasts, and exercise practitioners who implement steel mace training programs.

Inter-Repetition Rest Interval Affects Peak Power Independent Of Its Rate Of Development
 William P. Lydon, Marie R. Acosta, Alexia E. Amo, J. Mark VanNess, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
 Email: w_lydon@u.pacific.edu
(No relevant relationships reported)

Numerous variables influence performance in resistance training. The duration between sets has been explored both for its acute effect on the subsequent set as well as its effect on the physiological responses to exercise. However, the duration of rest between repetitions is relatively unexplored. **PURPOSE:** To evaluate the effect of inter-repetition rest interval (IRRI) duration on power parameters within a single set. **METHODS:** We tested 206 healthy men and women between the ages of 15 and 70 using Proteus technology (Proteus Motion, USA). Subjects performed

36,728 repetitions across 4,566 sets of 25 exercises at various loads (1lb to 25lb) of three-dimensional isotonic resistance. Proteus software calculated the IRR duration (milliseconds) and each repetition's peak power (watts) and peak force development rate (watts/sec). Linear regression models tested the effect of IRR duration on the peak power and peak force development rate of the subsequent repetition while controlling for other significant predictors. **RESULTS:** In upper body motions, holding constant exercise performed ($p<0.001$), resistance applied ($p<0.001$), and repetition number ($p=0.045$), each additional second of IRR predicted a 2.23-watt increase of peak power in the next repetition ($p<0.001$; 95% CI: 1.81-2.65). The overall model was significant ($R^2=0.613$; $p<0.001$). Lower limb motions displayed a similar pattern ($R^2=0.620$; $p<0.001$) but the magnitude of effect by IRR duration was smaller ($p=0.001$; $\beta=1.13$; 95% CI: 0.67-1.59). Lower limb peak force development rate was unaffected by IRR ($p=0.714$); in upper body motions, there was a weak negative trend ($\beta=-2.08$; $p=0.090$). At loads under 20lb, IRR was less influential to performance; for loads of 20-25lb, the optimal IRR duration was 2.50-3.00 seconds. Holding confounders constant, repetitions that followed this duration of IRR experienced a 40.99-watt increase in power ($p<0.001$; 95% CI: 17.76-64.22). That duration had no effect on peak force development rate ($p=0.443$). **CONCLUSIONS:** Performance in resistance training is affected by innumerable factors. Our findings add one more for consideration: the duration of rest between repetitions within a single set. To achieve maximum power in the subsequent repetition, a rest interval of 2.50 to 3.00 seconds appears ideal.

2576 Board #37 May 29 9:30 AM - 11:00 AM
Evaluation Of Stretch Shortening Cycle Performance Of Upper Limbs

Kazufumi Terada, Toshiaki Nakatani. *Faculty of Budo & Sport Studies, Tenri University, Tenri, Nara, Japan.*

Email: terada@sta.tenri-u.ac.jp

(No relevant relationships reported)

PURPOSE: The purpose of this study was to suggest an indicator for the Rebound Jump-index (RJ-index) of upper limbs that reflects the Stretch-Shortening Cycle performance (SSC performance) of the upper limbs, and elucidate the inter-trial reliability and the criterion-related validity of this indicator.

METHODS: The subjects were 31 male university track-and-field athletes between the ages of 18 and 21 years. Using an optical sensor, five rebound jumps with the upper limbs were performed on-site, and a jump height derived from the ground contact time and airborne time was calculated. The jump height was further divided by the ground contact time, and treated as the RJ-index of the upper limbs. For the rebound jumps, we instructed the subjects to keep their elbows as straight as possible during ground contact, keep the ground contact time short, and jump high. At the start of measurement, the hip joint angle was fixed to be 0°, and both upper limbs were kept perpendicular to the floor. In order to verify the reproducibility (inter-trial reliability) of the RJ-index measurement values of the upper limbs, we performed the same measurements 2 weeks later and derived the intraclass correlation coefficients (ICC) between the measurement values. In addition, to assess the criterion-related validity of the RJ-index of the upper limbs, we performed to the correlation between the RJ-index measurement and the shot put records.

RESULTS: ICC (1,1) between the RJ-index measurement of upper limbs (0.19+0.07) and the re-measurement (0.18+0.08) was $\rho=0.83$, and ICC (1,2) was $\rho=0.91$. These values indicate that the measurement reproducibility was relatively high. Upon deriving the partial correlation coefficient assuming age and weight as control variables, a relatively high correlation was seen between the RJ-index of the upper limbs and the shot put records ($r=0.59$, $p<0.01$).

CONCLUSIONS: Therefore, we think that it is apparent that the RJ-index of the upper limbs had a definite inter-trial reliability and this test may possibly have criterion-related validity as an assessment test for SCC performance of the upper limbs.

Muscular Excitation Is Not Greater During Conventional Arm Care Exercises Than During Overarm Throwing

Brady M. Volmering¹, Jarod M. Burton¹, James R. Sackett².
¹DAC Baseball, Ozark, MO. ²Cornerstone University, Grand Rapids, MI.

(No relevant relationships reported)

Conventional arm care exercises include the use of rubber tubing (Jaeger Bands) and soft weighted balls (Plyocare Balls). It is postulated that these training devices may be used to prepare the arm for the forces present during overarm throwing. However, little research exists on the physiological effect of conventional arm care exercises.

PURPOSE: To test the hypothesis that muscular excitation is greater during conventional arm care exercises than overarm throwing.

METHODS: Nineteen males (age: 21 y, BMI: 26.6 kg/m²) participated in this investigation. Two independent wireless surface electromyography (sEMG) devices

(Somaxis Cricket) were used to assess muscular excitation of the shoulder (SH) and the forearm (FA). Following a standardized warm-up, maximal voluntary isometric contractions (MVIC) of the SH and FA were measured. Each visit consisted of various Jaeger Band Exercises targeting SH rotation and Plyocare Ball Exercises targeting arm force absorption. The arm care exercises were compared to overarm throwing via a one-way ANOVA and a Pearson correlation. Data are presented as a percentage (%) of MVIC (mean±SD).

RESULTS: Peak sEMG amplitude of the SH was not significantly different for Jaeger Band External Rotation (45±22%, $p=0.91$), Reverse Throw Green (55±21%, $p>0.99$), and Rebounders Black (41±16%, $p=0.35$) when compared to overarm throwing (56±21%). Peak sEMG amplitude of the FA was not significantly different for Jaeger Bands External Rotation (45±31%, $p=0.06$), Reverse Throw Green (57±22%, $p=0.46$), and Rebounders Black (72±22%, $p>0.99$) when compared to overarm throwing (72±17%). For the SH, Jaeger Bands External Rotation ($r=-0.18$, $p=0.24$), Reverse Throw Green ($r=-0.03$, $p=0.46$), and Rebounders Black ($r=0.16$, $p=0.27$) were not significantly correlated with overarm throwing. For the FA, Jaeger Bands External Rotation ($r=0.43$, $p=0.04$) was significantly correlated, while reverse Throw Green ($r=0.15$, $p=0.27$) and Rebounders ($r=0.39$, $p=0.06$) were not significantly correlated with overarm throwing.

CONCLUSION: These data indicate that conventional arm care exercises do not generate greater muscular excitation than overarm throwing. Therefore, it does not appear that these arm care exercises adequately prepare the arm to throw at high velocities.

2578 Board #39 May 29 9:30 AM - 11:00 AM
Overspeed Exercises Of The Arm Produces Greater Muscular Excitation Than An Overarm Throw

Jarod M. Burton¹, Brady M. Volmering¹, James R. Sackett².

¹DAC Baseball, Ozark, MO. ²Cornerstone University, Grand Rapids, MI.

(No relevant relationships reported)

Overspeed (OS) training is used to train the body at speeds that are faster than regular competitive speeds. To this end, OS training enhances muscular rate coding, which leads to muscular adaptation. Recently, OS training of the legs with resistance bands was shown to increase vertical jump height in trained males. However, little is known about OS training of the arm as it relates to an overarm throw.

PURPOSE: To test the hypothesis that muscular excitation of the arm is greater during OS training than an overarm throw.

METHODS: Nineteen males (age: 21 y, BMI: 26.6 kg/m²) completed four visits to the laboratory. Muscular excitation of the anterior forearm (FA) and posterior shoulder (SH) were assessed using two independent wireless surface electromyography (sEMG) devices (Somaxis Cricket). Maximal voluntary isometric contractions (MVIC) of the FA and SH were assessed after a standardized warm-up. Each visit consisted of various band assisted OS exercises. In general, the subject placed their arm between a stretched resistance band and moved their arm at maximum intent for ~six seconds. The position of the body was dependent upon the exercise and the amount of weight in the hand varied. The exercises were compared to an overarm throw via a one-way ANOVA and a Pearson correlation. Data are presented as a percentage (%) of MVIC (mean±SD).

RESULTS: Peak sEMG amplitude of the FA was significantly greater for the OS Unweighted Shoulder Y (110±33%, $p=0.01$) and the OS Weighted Drop Shoulder Y (95±27%, $p=0.01$) when compared to the overarm throw (72±17%). Peak sEMG amplitude of the SH was significantly greater for the OS Unweighted Shoulder Y (82±29%, $p=0.03$) when compared to an overarm throw (56±21%). Peak sEMG amplitude of the SH was not significantly different for the OS Weighted Drop Shoulder Y (65±21%, $p=0.39$) than the overarm throw. For the FA, OS Unweighted Shoulder Y ($r=0.57$, $p<0.01$) and OS Weighted Drop Shoulder Y ($r=0.72$, $p<0.01$) were significantly correlated with overarm throwing. For the SH, OS Unweighted Shoulder Y ($r=0.52$, $p=0.01$) and OS Weighted Drop Shoulder Y ($r=0.77$, $p<0.01$) were significantly correlated with overarm throwing.

CONCLUSION: These data indicate that OS training generates greater peak sEMG amplitude than an overarm throw. Yet, it remains unclear whether OS training will enhance throwing velocity.

Differences In Quadriceps Muscle Endurance Between Healthy Males And Females

Morgan R. Dearing, Lauren N. Erickson, Kylie A. Davis, Christopher S. Fry, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.*

(No relevant relationships reported)

Muscle endurance is critical for many sports, but is rarely assessed. Previous work has used a sustained contraction to measure muscle endurance, finding that females have greater endurance than males. However, a sustained contraction results in greater ischemia and is driven by peak strength. Thus, new clinical assessments of muscle endurance that overcome this challenge are needed. **PURPOSE:** To evaluate

quadriceps endurance between healthy males and females, and compare quadriceps endurance to quadriceps strength. **METHODS:** 19 healthy subjects (10 M, 26.8 ± 7.6 y; 77.6 ± 12.2 kg; 9 F, 23.8 ± 7.3 y; 60.4 ± 6.2 kg; Tegner 7.0 ± 0.9) participated in this study. Leg dominance was self-reported. Maximum voluntary isometric contraction (MVIC) and endurance were assessed at 90° of flexion on a Biodex dynamometer. Endurance was assessed via 5-second contractions followed by 3-second rests at a target of 70% MVIC. Once the subject's torque output fell below 50% of the target for 3 repetitions, the test was completed. Endurance was calculated as the area under the torque curve summed across repetitions. Independent t-tests compared differences between males and females. Pearson product moment correlation coefficients assessed the relationship between quadriceps strength and endurance. **RESULTS:** There were no significant differences in peak isometric strength normalized to body weight (M: 2.6 ± 0.6 Nm/kg, F: 2.6 ± 0.5 Nm/kg), nor was there a relationship between cumulative work and peak strength (p = 0.85, r = -0.05), age (p = 0.22, r = 0.30) or bodyweight (p = 0.31, r = 0.25). Males displayed greater cumulative work than females (M: 242.9 ± 127.3 Nm*s/kg, F: 142.9 ± 71.6 Nm*s/kg, p = 0.05). Both males and females showed significantly greater endurance in the dominant limb (Dominant: 194.9 ± 114.3; Non-dominant: 122.2 ± 55.3; p = 0.003). **CONCLUSIONS:** The muscle endurance test was not influenced by strength, age, or bodyweight. However, we did find significant differences in limb dominance which could be due to greater use of the dominant limb. In contrast to prior studies, males had greater endurance. We speculate that this could be due to differences in how the muscle reperuses during rest periods. Future work should assess if these differences carry over after injury and evaluate the physiological determinants for the observed differences.

Water Vs. Land-based Squat Exercise In Postmenopausal Women: Effects On Neuromuscular Activity And Metabolic Equivalents

Kuei-Yu Chien¹, Wan-Chin Chen², Wen-Sheng Zhou³, Ting-Hui Joanna Kuo¹. ¹National Taiwan Sport University, Taoyuan, Taiwan. ²University of Taipei, Taipei, Taiwan. ³Nanjing Xiaozhuang University, Nanjing, China.
 Email: chienkueiyu@gmail.com
 (No relevant relationships reported)

Overweight and obesity are osteoarthritis (OA) risk factors. The prevalence of OA in women is higher than that of men. The squat exercise is a simple and effective strength training mode for lower extremities. The buoyancy and warm temperature of the water can reduce joint discomfort during the squat exercise. However, it is unclear the responses of neuromuscular activity (MA) and metabolic equivalents (METs) when squat exercise at different speeds was performed. **PURPOSE:** This study was to compare the responses of MA, rating of perceived exertion (RPE), and METs following squat exercise at slow (20bpm), medium (60bpm), and the fast as possible speed between in water and on-land in postmenopausal women. We recruited 23 postmenopausal women over the age of 50 with a BMI ≥ 24 or body fat ≥ 30%. Participants performed 15 repetitions squat exercise at medium speed, slow speed and fast speed in water and on land by random order. We measured the maximum voluntary contractions of quadriceps and hamstring muscle and standing posture oxygen consumption before exercise testing and collected RPE, METs, and MA in the exercise period. Paired-samples t tests were performed to test all parameters in water and on land. **RESULTS:** MA of quadriceps in water were significantly lower than that on land at three-speed squat exercise (slow: 11.95±3.93 vs 31.21±10.70, medium 17.02 ±5.31 vs 42.79±16.46, the fastest: 30.48±7.74 vs. 72.12±25.86 rms %, p<0.05). MA of hamstring was no difference between in water and on land following medium and fast-speed squat exercise. The METs in water were lower than that of on land at slow and medium speed squat exercise (slow: 1.73±0.37 vs.2.40±0.40, medium: 1.91±0.35 vs. 2.34 ±0.42, the fastest: 2.21±0.79 vs. 2.50±0.63, p<0.05). The RPE responses of squat exercise at all speeds in water were lower than that of on land (slow: 2.04±0.64 vs. 3.00±1.16, medium: 1.91±0.60 vs. 2.61 ±1.08, the fastest: 2.21±0.85 vs. 3.39±1.34, p<0.05). Conclusion: The responses of MA of hamstring and METs following the fastest-speed squat exercise were similar to those of on land, whereas it had a lower RPE.

Different Methods Of Post Activation Potential On Swimming

Humberto Miranda¹, Paolo Sirieoi¹, Igor Nasser¹, Gabriel Andrade Paz¹, Ward Dobbs². ¹Federal University of Rio de Janeiro, Rio de Janeiro, Brazil. ²University of Wisconsin-La Crosse, Wisconsin, WI.
 Email: humbertomiranda@cefd.ufrj.br
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to compare the effect of post-activation potentiation (PAP) on countermovement jump (CMJ) using different set configurations and loads on conditioning activity (CA) in highly trained swimmers.

METHODS: Sixteen national level swimmers participated in this study and performed a total of six visits to the laboratory. The first session was used for familiarization, the second session was utilized to determine a five repetitions maximum (RM) in the half squat (HS), and the following four visits consisted of four CA protocols performed in a counterbalanced order. Two CAs were performed as traditional sets (TS) with sequential repetition, with different load, which involved one set of five repetitions at 100% (TS₁₀₀) or 65% of 5 RM load (TS₆₅). Additionally, two CAs included one set of five repetitions with intraset rests, 30 second interrepetition rest (IRR), with both relative loads (IRR₁₀₀ and IRR₆₅). Countermovement jump height was measured at baseline, immediately after the CA, and every 2-min until 12-min. **RESULTS:** Significantly faster peak and mean barbell velocity was observed for the CAs with lower relative loads (p < 0.05). When evaluating the peak CMJ height, considered the best result after the CA, TS₁₀₀ improved CMJ performance (effect size = 0.39; p = 0.027; Δ% = 4.8 ± 7.3). **CONCLUSIONS:** Thus, set configuration using IRR does not promote PAP and TS with a high-load should be adopted for an acute improvement in CMJ for highly trained swimmers.

The Effect Of Reflexive Performance Reset And Gluteal Activation Exercises On Muscular Excitation During Sprints

Kevin A. Slowik¹, Jarod M. Burton², Nathaniel J. Farrell¹, Brady M. Volmering², James R. Sackett¹. ¹Cornerstone University, Grand Rapids, MI. ²Decide. Act. Conquer. Baseball, Ozark, MO.
 (No relevant relationships reported)

Reflexive performance reset (RPR) has been reported to mitigate compensation patterns to reduce pain, increase flexibility, and enhance performance during sport and exercise. Furthermore, gluteal activation exercises (GA) have been postulated to enhance gluteal recruitment during exercise. However, it is currently unknown whether RPR or GA alter muscular excitation during exercise.

PURPOSE: To test the hypothesis that RPR improves hamstring excitation and GA improves glutei maximi excitation when compared to a dynamic warm-up.

METHODS: Ten male subjects (age: 21±1 y, BMI: 25.2±2.4 kg/m²) randomly completed a control visit (Control), a RPR visit (RPR), and a GA (GA) visit. Whole-body feeling was assessed using the feeling scale (-5=very bad, 0=neutral, 5=very good) and sprint time was assessed using slow motion video capture. The total contribution of muscular work was assessed for the quadriceps, the glutei maximi, and the hamstrings using surface electromyography (Athos Training System). Subjects performed a standardized dynamic warm-up (Control), had RPR performed on them by a trained technician (RPR), or completed a series gluteal activation exercises (GA). Maximal voluntary isometric contractions for the quadriceps, the glutei maximi, and the hamstrings were assessed, after which the subject ran three all-out 9.14 m sprints. The feeling scale and sprint time were analyzed via a one-way ANOVA and the total contribution of muscular work was analyzed via a two-way ANOVA. Data are presented as mean±SD.

RESULTS: There were no statistical differences between Control (2.9±1.4 a.u.), RPR (2.9±1.6 a.u.), or GA (3.2±1.7 a.u.) for the feeling scale (p=0.80). There were no statistical differences between Control (2.01±0.03 s), RPR (2.02±0.07 s), or GA (1.93±0.31 s) for sprint time (p=0.48). Total muscular contribution was not statistically different (condition main effect: p=0.90) during Control (quadriceps: 70±12%, glutei maximi: 16±8%, hamstrings: 14±9%), RPR (quadriceps: 61±11%, glutei maximi: 17±5%, hamstrings: 22±8%), or GA (quadriceps: 65±11%, glutei maximi: 17±5%, hamstrings: 18±8%).

CONCLUSION: These data indicate no alterations in muscular excitation following RPR or GA during short sprints in healthy males. Furthermore, RPR or GA did not enhance whole-body feeling or performance.

Case Study: Shoulder Muscle Activity While Swimming With Different Wetsuit Conditions And Swimming Paces.

Boram Lim, Alina Swafford, Cordero Roche, John A. Mercer, FACSM. University of Nevada, Las Vegas, Las Vegas, NV.
 (Sponsor: John A. Mercer, FACSM)
 Email: boram.lim@unlv.edu
 (No relevant relationships reported)

During swimming, the wetsuit is an important piece of equipment can benefit swim performance. Triathletes can select different types of wetsuit based on personal preference, body type, and swimming technique. It is not clear if wetsuit design or swim pace influences shoulder muscle activity. **Purpose:** To determine how swimming with different types of wetsuit (HUUB design., Aegis II 3:5, Sphere) using different swimming paces influence shoulder muscle activity. **Methods:** One male subject (height: 181.6cm, body mass: 81.1kg) completed total four swim conditions in a 25 m pool: 1) No wetsuit (NWS), 2) Sleeveless wetsuit (SLW), 3) Full-sleeve

wetsuit (FSW), 4) Buoyancy shorts (BS) x 3 swimming paces: slow, medium, fast. A wireless waterproof EMG system (Cometa, Italy) was used to measure shoulder electromyography (EMG) (Anterior Deltoid: AD & Posterior Deltoid: PD) and swimming pace was measured by stopwatch. EMG data were averaged across 5 consecutive stroke cycles with stroke rate calculated. EMG data were normalized to NWS slow speed. **Results:** Stroke rate (slow: 1.92 ± 0.05 Hz, medium: 1.75 ± 0.05 Hz, fast: 1.46 ± 0.06 Hz) decreased as swimming velocity (m/s) increased (NWS - Slow: 1.12 ± 0.04 , Medium: 1.21 ± 0.02 , Fast: 1.32 ± 0.01 / SLW - Slow: 1.27 ± 0.02 , Medium: 1.34 ± 0.01 , Fast: 1.52 ± 0.01 / FSW - Slow: 1.25 ± 0.02 , Medium: 1.38 ± 0.02 , Fast: 1.48 ± 0.04 / BS - Slow: 1.21 ± 0.02 , Medium: 1.30 ± 0.01 , Fast: 1.40 ± 0.02). Inspecting EMG trends, AD EMG was greatest during BS vs. other conditions and increased with swim velocity during FSW and BS conditions. PD muscle activity did not exhibit any clear pattern between conditions or across swimming velocities. Table 1. Anterior and posterior deltoid muscle activities (%NWS slow) across the wetsuit conditions.

Condition	Anterior Deltoid			Posterior Deltoid		
	Slow	Medium	Fast	Slow	Medium	Fast
NWS	79.9 ± 19.4	73.7 ± 1.1	80.4 ± 4.8	93.8 ± 7.4	75.9 ± 33.4	87.7 ± 21.1
SLW	92.2 ± 13.2	76.1 ± 1.8	81.1 ± 2.2	102.7 ± 22.6	187.7 ± 22.2	157.3 ± 8.9
FSW	65.2 ± 3.6	76.8 ± 4.3	103.5 ± 14.9	162.1 ± 26.5	121.1 ± 3.7	149.3 ± 1.4
BS	111.7 ± 1.6	122.8 ± 5.7	149.4 ± 9.3	98.6 ± 48.5	83.4 ± 60.4	83.1 ± 48.2

Note: Anterior Deltoid and Posterior Deltoid as percent of Slow-No Wetsuit (NWS) condition during sleeveless wetsuit (SLW), full sleeve wetsuit (FSW), and neoprene shorts (BS).

Conclusion: It is important to establish techniques to measure muscle activity during swimming in different wetsuit conditions since muscle activity is influenced by a complex interaction of wetsuit condition, pace, and swim technique.

2584 Board #45 May 29 9:30 AM - 11:00 AM
How Do Different Forms Of Feedback Effect Maximal Voluntary Force In The Forearm Flexors?

William Miller, Sunggun Jeon, Jun Seob Song, Minsoo Kang, FACSM, Xin Ye. *University of Mississippi, University, MS.*
 (Sponsor: Dr. Minsoo Kang, FACSM)
 Email: wmmille2@olemiss.edu
 (No relevant relationships reported)

Biofeedback provides a unique stimulus enhancement to the maximal voluntary isometric contraction (MVIC) ability in several muscle groups. However, limited research has investigated the use of biofeedback in the upper extremities specifically, the forearm flexors (FF). **PURPOSE:** The purpose of this study was to examine whether different methods of biofeedback affect the maximal force achieved during the FF MVIC test. **METHODS:** Twenty subjects (10 Male) consented to participate in this randomized counter-balanced experiment. In a single visit, subjects were exposed to the following conditions whilst performing the FF MVIC test. These included, 1) Visual and verbal feedback (VIVE); 2) Verbal feedback only (VE); 3) Visual feedback only (VI); and 4) no feedback at all (NOVIVE). Real-time force output was displayed on a monitor for VIVE and VI, and loud standardized verbal encouragement of 'pull, pull, pull' was utilized for VIVE and VE. For each condition, a total of three, 5-second MVIC trials were completed with a two-minute rest between each trial. In addition, a 5-minute rest was provided between consecutive conditions. A 4 x 2 repeated measures ANOVA was performed using the peak MVIC (in Newton) with a significance level set at 0.05. Condition (VIVE vs. VE vs. VI vs. NOVIVE) was a within subject factor and sex (Male vs. Female) was a between subject factor. **RESULTS:** A significant main effect for condition ($p < .001$) but no interaction was revealed, with follow-up Bonferroni-adjusted pairwise comparisons demonstrating significantly greater force production in the VIVE compared to VE (mean ± standard error (SE): 330.80 ± 16.09 vs. 310.62 ± 15.51 , $p = .006$), and NOVIVE (mean ± SE: 330.80 ± 16.09 vs. 304.42 ± 15.88 , $p = .001$) conditions; as well as, significantly greater force production in the VI compared to VE (mean ± SE: 327.24 ± 15.84 vs. 310.62 ± 15.51 , $p < .001$), and NOVIVE (mean ± SE: 327.24 ± 15.84 vs. 304.42 ± 15.88 , $p = .004$) conditions. **CONCLUSIONS:** The main finding is that both VIVE and VI biofeedback provide the most effective form of encouragement during FF MVIC tests by demonstrating the greatest force output. Many studies commonly include VE feedback only, however, here we demonstrate the importance of providing VI biofeedback. Therefore, it is suggested that future studies include VIVE feedback during MVIC trials in the FF.

2585 Board #46 May 29 9:30 AM - 11:00 AM
The Effect Of Vibrating Foam Roller Exercise On Bilateral Ankle Proprioception In Basketball Players

Bowen Liu¹, Jeremy Witchalls², Gordon Waddington², Roger Adams², Sam Wu³, Jia Han¹. ¹Shanghai university of sport, Shanghai, China. ²University of Canberra, Canberra, Australia. ³Swinburne University of Technology, Melbourne, Australia.
 Email: small_brown@163.com
 (No relevant relationships reported)

PURPOSE: Research evidence has shown hemispheric specialization in the utilization of proprioception. The purpose of this study was to investigate the immediate effect vibrating foam roller exercise (VFRE) on bilateral ankle proprioception in recreational basketball players (RBP). **METHODS:** This was a randomized cross-over study. Twenty-two right-footed male RBP (Age = 23.6 ± 0.3) volunteered. After baseline assessment of ankle proprioception in barefoot, RBP were randomly assigned to either vibrating the peroneal muscle (VFRE-p, $n = 11$) or the gastrocnemius muscle (VFRE-g, $n = 11$) group. Bilateral ankle proprioception was re-assessed after VFRE. After 24h washout, the two groups swapped exercise and bilateral ankle proprioception was re-assessed. The VFRE for each muscle group was 3x30s vibration at the frequency of 50 Hz, with a 30s rest between sets. Ankle proprioception was measured by active movement extent discrimination apparatus (AMEDA). Repeated measures and Pearson's correlation was used to analyze the data. **RESULTS:** There was no significant Side ($R = 0.411$, $p = 0.057$), Muscle or Time effect ($F = 0.826$, $p = 0.445$; $F = 0.441$, $p = 0.647$, respectively). However, when RBP were divided into superior (SG, $n = 11$) and inferior (IG, $n = 11$) groups, according to the median of bilateral ankle proprioception, we found: 1) the dominant right ankle proprioception worsen significantly after both VFRE-p ($p = 0.022$) and VFRE-g ($p = 0.02$) in the SG, but not in the IG ($F = 1.748$, $p = 0.2$); 2) the non-dominant left ankle proprioception improved significantly after both VFRE-p ($p = 0.046$) and VFRE-g ($p = 0.01$) in the IG, but not in the SG ($F = 1.461$, $p = 0.256$). These findings suggest that VFRE can impair the dominant right ankle proprioceptive performance in those who initially have superior proprioception, and conversely improve the non-dominant left ankle proprioceptive performance in those who initially have inferior proprioception. **CONCLUSIONS:** This study has revealed a novel hemispheric specialization effect in proprioceptive information processing associated with VFRE. Specifically, VFRE affects proprioception of the dominant and non-dominant hemispheric systems differently suggesting that the clinical application of VFRE should be considered regarding each individual's initial ankle proprioception and footedness.

Comparison Of Warm-Up Strategies On Internal And External Rotation Mechanics In Collegiate Pitchers

Christopher B. Perry, William P. Lydon, J. Mark VanNess, Alexia E. Amo, Cameron A. Williams, Courtney D. Jensen. *University of the Pacific, Stockton, CA.*
 Email: C_perry2@u.pacific.edu
 (No relevant relationships reported)

Rotator cuff strains are the most common musculoskeletal injury in collegiate baseball pitchers. A variety of warm-up routines are employed, the effects of these routines on the subsequent function of the rotator cuff lack comparison. **PURPOSE:** To test the effect of four different warm-up routines on internal (IR) and external rotation (ER) shoulder kinematics. **METHODS:** Seven D1 collegiate pitchers were enrolled in an experiment involving four testing sessions. Each session began with one of four warm-up protocols: 1) Jaeger bands (JB), 2) standard dynamic warm-up (DW), 3) Jaeger bands and standard dynamic warm-up (JBDW), or 4) dynamic warm-up using collinear resistance (CR). Immediately after the warm-up, athletes underwent biomechanical analysis of internal and external shoulder rotation using Proteus (Proteus Motion, USA). They performed 12 repetitions of each motion using 5lb of 3D magnetic resistance. 48 hours of rest separated each session. The assigned sequence of protocols was counter-balanced. Proteus software computed peak power in watts (w), peak force development rate in watts/second, range of motion in meters (ROM), consistency (the ability to replicate ROM in three-dimensional space), and endurance (replication of power parameters in successive repetitions). A one-way repeated measures ANOVA was used. **RESULTS:** Subjects were 20.4 ± 1.4 years of age. Across all conditions, peak power was 96.3 ± 13.7 w in IR and 99.3 ± 15.7 w in ER; peak force development rate was 387.7 ± 118.5 w/sec in IR, and 418.7 ± 195.6 w/sec in ER. Differences were detected in the four warm-up conditions in peak power (CR highest; $p = 0.015$), peak force development rate (CR highest; $p = 0.072$), and ROM (CR highest; $p = 0.015$). No difference was found in deceleration ($p = 0.336$), consistency ($p = 0.903$), or endurance ($p = 0.769$). External rotation was different in the four warm-up conditions in peak force development rate (CR highest; $p = 0.045$). No statistical difference was found in power (CR was highest, but did not reach significance; $p = 0.104$), deceleration ($p = 0.520$), consistency ($p = 0.478$), endurance ($p = 0.145$), or ROM ($p = 0.543$). **CONCLUSION:**

The simulated dynamic warm-up using three-dimensional resistance elicited the best subsequent function, follow up studies should examine mechanisms that produce this difference.

The Relationship Between Mountain Bike Seat Tube Angle, Knee-pedal Alignment, And Knee Range Of Motion

Kyle E. Petersen, Andrew Creer, Shane Draper, Anthony Ciccone. *Utah Valley University, Orem, UT.*
(No relevant relationships reported)

PURPOSE: Newer bicycles have increasingly steep seat tube angles. Seat tube angle (STA) is consistent within each bike model, but changes with seat height and post positioning. Traditionally, a bike fit will vertically align the knee with the pedal at the midpoint of the downstroke. This positioning has an effect on a rider's knee range-of-motion (ROM) potentially affecting fatigue rates. Additionally, the ROM may affect the knee-pedal spindle alignment position thereby affecting power capacity. Therefore, the purpose of this study was to determine if effective seat tube angle affects knee-pedal alignment and knee ROM.

METHODS: Participants included 17 male and female (176.9 ± 3.9 cm, 66.6 ± 25.4 kg), amateur and elite, cross-country mountain bike racers. Reflective markers were placed by the same researcher at locations on the participants dominant side: greater trochanter of femur, lateral condyle of femur, and lateral malleolus of fibula. Photographs were taken of the bike alone and with the participant in their typical riding position, with leg at full extension, full flexion, and halfway through the downstroke. Photographs were analyzed to determine knee-to-spindle horizontal distance (KTS), peak knee flexion angle (KFA), and STA using digital measurement software (Dartfish USA, Alpharetta, GA). Linear regression was used to statistically analyze the data (alpha=0.05).

RESULTS: For every 1 degree increase in STA, knee position moved forward 1.42 cm closer to the handlebars (p=0.050, R²= 0.23). After accounting for STA, KFA explained an additional 44% of the variance in KTS (p<0.001) where every 1 degree increase in KFA resulted in knee position moving 0.58 cm further away from the handlebars. When combined, STA and KFA explain 67% of the variance in KTS.

CONCLUSIONS: It is generally accepted that KTS should be 0 to have optimal power transfer to the pedals and limit sagittal forces on the knee joint. Changing STA in order to decrease KTS may be effective to increase performance. Further research should examine how individualized STA could affect rider positioning and performance during endurance efforts.

Energy Resource Of Four Styles Of 30s All-out Rope Skipping

Changjian Du, Li Guo. *Shanghai University of Sport, Shanghai, China.*
 Email: 494943064@qq.com
(No relevant relationships reported)

Rope jumping has been popular and a major tool for training and entertainment. When skipping rate per jump increments from single under to quad under, flight time prolonged and increased swinging frequency, the proportion of aerobic and anaerobic energy supply may be different.

Purpose: To compare 30-s all-out rope skipping energy resource between four styles.

Method: 10 elite rope-skipper from Shanghai University of Sport (height=169.3±4.7cm; body mass=65.5±9.2kg; age=23.2±2.1 yrs, years of training=3.8±1.3 yrs) volunteered for this study. Participants conducted 30-second rope skipping test at 1 skip per jump (single under, SU), 2 skip per jump (double under, DU), 3 skip per jump (triple under, TU) and 4 skip per jump (quad under, QU), and completed as many repetitions as possible with 24 hours between trials. VO₂ were monitored at rest, during test and up to 1 hour after test. Blood lactate was measured immediately, minute by minute after test. Lactic (W_{bla}) and alactic anaerobic (W_{pcr}) energy outputs were calculated from net lactate production and the fast component of EPOC. Aerobic metabolism (W_{acr}) was determined from VO₂ during exercise. Net energy expenditure (W_{tot}) was calculated as summary of W_{pcr}, W_{bla} and W_{acr}.

Result: SU exhibited significantly lower W_{tot} value (49.9±12.70 kJ) than in DU (69.2±11.05), TU (72.0±13.59) and QU (81.0±16.25) (p<0.01). W_{pcr} (kJ) was significantly different between SU (23.4±6.9), TU (33.7±12.8) and QU (40.0±10.5) (p<0.05), and DU (29.1±8.0) and QU (p<0.05). W_{bla} (kJ) in SU and QU were significantly different (16.5±6.8 v.s 27.2±12.4, p<0.05). SU (10.0±2.2) had

significantly lower W_{acr} (kJ) value than the other styles (DU 12.3±3.1, TU 14.8±2.4, QU 13.7±3.7, p<0.05). W_{pcr} and W_{bla} accounted for 45.6%~50.2% and 32.2%~35.3% of total energy in four styles with no difference between styles (p>0.05). Aerobic provided 16.8~22.1% of total energy in all styles, with significant difference between SU and QU (20.6±4.8% v.s 16.8 ±2.5%, p<0.05), TU (22.1±8.6%) and QU (p<0.05). **Conclusion:** Four styles of 30s all-out rope skipping are all anaerobic-dominated with similar fractions, PCr and anaerobic lactic account for 45.6%~50.2% and 32.2%~35.3% of total energy.

Keywords: rope skipping, metabolism, energy resource

Physiological Responses And Energetic Of Two Sprint Interval Exercise Protocols Based On Rope-skipping And Cycling

Ting Zhao, Li Guo. *Shanghai University of Sport, Shanghai, China.*
 Email: 1158552475@qq.com
(No relevant relationships reported)

High-intensity interval training could improve performance effectively. However, the acute physiological response and energy expenditure of a low-volume, high-intensity rope-skipping based protocol have not been determined.

PURPOSE: To compare the physiological response and energy resource in repeated bouts of sprint interval cycling (SIC) and high-intensity intermittent double-under rope skipping (HIT-RS).

METHOD: Fifteen college students (age=20.2±0.8 yrs, body mass=67.7±4.8kg, BMI=22.4±1.2kg.m², VO_{2peak}=51.90±7.83ml.kg⁻¹.min⁻¹) volunteered for this study. Participants completed two protocols (4 30s with 4min active recovery) on separate days with 1 week between trials. VO₂ and heart rate were monitored at rest, during test and continue to 1 hour after test. Blood lactate was measured 3 minutes after each bout, and minute by minute after the last bout. Lactic (W_{bla}) and alactic anaerobic (W_{pcr}) energy outputs were calculated from net lactate production and the fast component of EPOC. Aerobic metabolism (W_{acr}) was determined from VO₂ during exercise.

RESULT: Mean values for %VO_{2peak} and %HR_{peak} for SIC (78.79±15.35% and 85.33±4.69%) and HIT-RS (74.93±16.21% and 83.17±5.37%) were not significantly different (p>0.05). The overall energy cost for SIC (102.75±13.15 kJ) was significantly higher (p<0.001) compared to HIT-RS (70.86±10.25 kJ). W_{acr}, W_{bla} and W_{pcr} for SIC (17.39±3.08, 59.50±8.10 and 25.86±5.40 kJ) and HIT-RS (13.05±2.01, 27.97±6.77 and 29.84±6.28 kJ) were significantly different (p<0.01). Fractions of W_{acr}, W_{bla} and W_{pcr} for SIC (16.92±1.77%, 57.99±4.70% and 25.09±3.65%) and HIT-RS (18.80±3.13%, 38.84±6.09% and 42.36±5.98%) were significantly different (p<0.001). Both protocols were anaerobic-dominated with similar fraction (SIC:83.08±3.01% vs HIT-RS: 81.20±4.52%). Compared to SIC, HIT-RS was more PCr dominant (42.36±5.98% vs 25.09±3.65%, p<0.01) with lower anaerobic lactic contribution (38.84±6.09% vs 57.99±4.70%, p<0.001).

Conclusion: High-intensity interval protocol of rope skipping elicits vigorous cardiorespiratory responses and may confer physiological adaptations and performance improvements resembling as SIC.

2590 Board #51 May 29 10:30 AM - 12:00 PM
Determinants Of Metabolic Cost During Four Styles Of 30-second Sprint Rope Skipping

Li Guo, Yaogang Han. *Shanghai Sport University, Shanghai, China.*
 Email: guoli@sus.edu.cn
(No relevant relationships reported)

Rope jumping has been a major training tool for many sports. However, no study has been conducted as yet to determine energy expenditure with incremental skipping rate per jump (difficulty) from single under to quad under.

Purpose: To determine and compare 30-seconds all-out effort energy expenditure between four incremental rope skipping difficulties.

Method: Ten skilled rope-jumpers (height=169.3±4.7cm, body mass=65.5±9.2kg, age=23.2±2.1 yrs, years of training=3.8±1.3 yrs) volunteered to participate this study. Participants conducted rope skipping as many repetitions as possible at 1 skip.jump⁻¹ (single under, SU), 2 skips.jump⁻¹ (double under, DU), 3 skips.jump⁻¹ (triple under, TU) and 4 skips.jump⁻¹ (quad under, QU) during 30-second test with 24 hours between trials. Kinematic and kinetic data were collected to calculate flight time (FT) and vertical center of mass displacement (vCOM). Each style was assessed in three trials and then averaged. Net energy expenditure (W_{tot}) was calculated from VO₂ during exercise, the fast component of the EPOC above resting and net blood lactate production.

Result: SU exhibited significantly lower VO_{2peak} (28.01±4.62 ml.kg⁻¹.min⁻¹, p<0.05) compared to TU (34.96±3.45) and QU (36.12±6.38). W_{tot} (J.jump⁻¹) in QU (7975.1±3265.66 J.jump⁻¹) was significantly higher than these values of the other three styles (SU 474.9±108.80, DU 1086.4±183.17, TU 1769.3±540.46, p<0.05). FT (ms) and vCOM (cm) increased significantly with increase in difficulty (SU: 125.0±19.6

and 1.95 ± 0.66 , DU: 276.6 ± 36.1 and 9.53 ± 2.24 , TU: 473.6 ± 32.1 and 27.64 ± 3.76 , QU: 544.4 ± 60.5 and 36.76 ± 8.15 , $p < 0.01$). 30s skip repetitions in QU (46.0 ± 19.34) was significantly lower than the other styles (SU 105.2 ± 12.08 , DU 128.2 ± 15.12 , TU 126.9 ± 20.39 , $p < 0.01$). Standard Workload (J.kg⁻¹.jump⁻¹) was exponentially related to skipping difficulty from 1 skip.jump⁻¹ to 4 skips.jump⁻¹ ($R^2 = 0.89$, $p < 0.001$). **Conclusion:** Skipping difficulty (skip per jump) is one of the main determinants of metabolic cost, whereas skip repetition does not significantly contribute to metabolic cost during 30 seconds all-out rope skipping.

2591 Board #52 May 29 10:30 AM - 12:00 PM
The Effects Of A Counterpulsation Auditory Prompt On Hemodynamics And Metabolism During Endurance Running

Derek W. Marks, Chi-An W. Emhoff. *Saint Mary's College of California, Moraga, CA.*

(No relevant relationships reported)

Recent studies in elite runners suggest that cardiocomotor synchronization, when step rate and heart rate naturally occur with a 1:1 ratio, can lead to hemodynamic advantages of counterpulsation when the foot strikes occur during the diastolic phase of the cardiac cycle. **PURPOSE:** Healthy non-elite runners were studied to investigate the hemodynamic and metabolic responses to prolonged counterpulsation by prompting individuals to step during the diastolic phase of their cardiac cycles during endurance running. We hypothesized that an auditory prompt that elicited counterpulsation would result in a lower heart rate, pulse pressure, respiratory exchange ratio (RER), ventilation and blood lactate, and higher oxygen consumption and blood glucose compared to an auditory prompt that did not elicit counterpulsation. **METHODS:** Fifteen healthy subjects (8 male, 7 female) completed two single-blinded sessions of 20-minutes of continuous treadmill running at an intensity of 60-80% of $\dot{V}O_{2max}$ in randomized order: 1) with an auditory prompt adaptive to the subject's real-time heart rate and stepping phase to guide diastolic stepping, and 2) with a non-adaptive, constant frequency auditory prompt set at each subject's natural step rate. Heart rate and indirect calorimetry were measured continuously throughout exercise followed by 10 minutes of sedentary recovery. Finger pricks for blood lactate and glucose were done every five minutes during exercise and every two minutes during recovery. Blood pressure was measured pre- and post-exercise and post-recovery. **RESULTS:** The adaptive auditory prompt successfully guided runners to step in diastole >75% of the steps and resulted in a significantly lower pulse pressure following the post-exercise recovery compared to the non-adaptive prompt (31 ± 2 vs. 36 ± 3 mmHg, $p < 0.05$). We also observed trends in lower heart rate (2-6 beats/min) and higher blood glucose (0.1-0.3 mM) during exercise guided by the adaptive auditory prompt compared to the non-adaptive prompt. No differences were observed in the other variables. **CONCLUSION:** Counterpulsation, through prompted cardiocomotor synchronization, may have hemodynamic advantages during and after endurance running in a healthy recreationally active population.

(No relevant relationships reported)

Hypertension is the leading risk factor for death and disability worldwide. Isometric handgrip (IHG) training is endorsed as one of the "Best Proven Nonpharmacological Interventions for Prevention and Treatment of Hypertension" by the American Heart Association/American College of Cardiology in their current guidelines. Barriers such as cost of the handgrip devices and tedium arising from repeating the same exercises, pose a challenge for widespread implementation of IHG training. Therefore, alternative devices that provide potential for a wide variety of isometric exercises warrant further investigation. **PURPOSE:** To determine whether an acute bout of IHG exercise, performed with a novel exercise ball (NEB), elicits similar cardiovascular responses and ratings of perceived exertion (RPE) to a traditional IHG device (TID). **METHODS:** Ten healthy adults (age: 24 ± 7 yrs; $\bar{Q} = 7$; systolic blood pressure (BP)/diastolic BP: $99/56 \pm 9/6$ mmHg) randomly performed two different IHG exercise protocols, one with the NEB, and the other with the TID. Both protocols involved 4, 2-min isometric contractions with 1-min rest periods between contractions, but NEB employed hand and adductor isometric contractions at 20-30% of maximum voluntary contraction (MVC), while the TID protocol involved alternating handgrip contractions performed at 30% of MVC. Heart rate (HR) and BP were recorded pre-, mid-, and post-exercise bout, as well as every 5-min during seated rest. RPE was assessed using the Borg CR-10 scale, following each contraction. The two protocol bouts were separated by 30-min of seated rest. **RESULTS:** The NEB and TID protocols elicited

similar HR and systolic BP responses ($p > 0.05$). However, the TID protocol elicited a greater diastolic BP response (12 ± 1 mmHg) than the NEB protocol (8 ± 1 mmHg; $p = 0.026$). Additionally, a higher RPE was observed for TID, compared to NEB ($p < 0.001$). **CONCLUSION:** This preliminary data suggests that the NEB protocol elicits similar cardiovascular responses (HR and systolic BP) while being perceived to require less effort, compared to the TID. Such an isometric exercise ball offers the potential for a wide variety of isometric exercises to be performed during training. Supported by University of Windsor Research Stimulus Fund Grant 813306

Evidence That Women With Polycystic Ovary Syndrome Exhibit Altered Vascular Function To High-intensity Exercise

Emily Brotherton¹, Michael Simmonds¹, Kieran Richardson¹, Lennart Kuck¹, Jacob Turner¹, Antony McNamee¹, Bryce Balmain², Surendran Sabapathy¹. ¹Griffith University, Gold Coast, Australia. ²Institute for Exercise and Environmental Medicine, and UT Southwestern Medical Center, Dallas, TX. Email: emily.brotherton@griffithuni.edu.au

(No relevant relationships reported)

PURPOSE: Women with Polycystic Ovary Syndrome (PCOS) have an increased risk of cardiovascular disease (CVD). The link between PCOS and CVD is believed to be related to vascular dysfunction. An integral component of the management and prevention of CVD is high-intensity (HI) exercise, which has been shown to improve vascular function. However, there is currently a lack of evidence regarding the vascular response following an acute HI exercise bout in PCOS. Therefore, we assessed vascular function via brachial artery flow-mediated dilation (FMD) in response to an acute HI treadmill exercise bout in women with PCOS and healthy controls (CON). **METHODS:** 8 PCOS (age: 26 ± 4 y; height 166 ± 5 cm; weight 66 ± 11 kg) and 10 CON (age: 28 ± 6 y; height 166 ± 7 cm; weight 59 ± 12 kg) were studied. All participants performed a maximal incremental treadmill test to determine peak oxygen uptake ($\dot{V}O_{2peak}$). On a separate day, subjects performed a 30min constant-load HI treadmill test at 75% of their individual $\dot{V}O_{2peak}$. FMD was measured at baseline (pre-HI) and immediately after (post-HI) exercise. A two-way group (PCOS vs CON) by time (pre-HI vs post-HI) analysis of variance was conducted. **RESULTS:** $\dot{V}O_{2peak}$ was similar between groups (PCOS: 2.78 ± 0.42 ; CON: 2.41 ± 0.48 L·min⁻¹, $p = 0.118$). The reduction in FMD post-HI was similar ($p = 0.985$) in PCOS ($-0.66 \pm 1.26\%$) and CON ($-0.47 \pm 0.79\%$). SRAUC increased ($p = 0.035$) in PCOS post-HI (4167 ± 6239 cm·s⁻¹), whereas a reduction ($p = 0.048$) was observed in CON (-4133 ± 7462 cm·s⁻¹). When FMD was normalized for shear rate, as defined by the area under the curve (SRAUC) following hyperaemia, the FMD:SRAUC ratio decreased ($p = 0.020$) to a greater extent in PCOS (-0.90 ± 0.84) compared with CON (0.03 ± 0.10) post-HI. **CONCLUSIONS:** Despite being young and active individuals, we provide new evidence that, for a given shear stress evoked by HI exercise, the impairment in vasodilatory function is worse in women with PCOS compared with CON. Whether this alteration in exercise-induced changes in vascular function plays a role in the elevated risk of developing CVD in this population is presently unclear. Further investigation into the underlying mechanisms of the altered vascular response to HI exercise in women with PCOS is warranted.

The Impact Of Age On Critical Speed And Distance: Insight From The Masters World Championships

Jayson R. Gifford, Jessica Collins. *Brigham Young University, Provo, UT.*

(No relevant relationships reported)

PURPOSE: The impact of age on critical speed (CS), the maximum sustainable speed a person can run under aerobic, steady-state conditions, and Distance-prime (D'), the finite amount of work a person can perform above CS, is unknown. The purpose of this study was to examine how CS and D' vary with age in a population of active adults. **METHODS:** In 2019, the World Masters Association held the Indoor Track and Field World Championships for masters athletes ranging from 35 to 100+ years old. Race times for the top 8 finishers of the 60-10,000m races for each 5-year age group (ages 35-75 yrs) and sex (Females: $n=72$, Males: $n=72$) were taken to explore the effect of age on the relationship between average running speed and distance (Univariate ANOVA). CS and D' were subsequently calculated using the 1/time method for all individuals who completed both the 1,500m and 3,000m events during the championships (Males: $n=63$, 35-85 yrs, Females: $n=39$, 35-80 yrs). Linear regression was then utilized to determine the relationship between age, CS and D'. **RESULTS:** A typical curvilinear relationship between speed and distance was observed for all ages and sexes (Panels A and B). There was a significant interaction between age and the speed-distance relationship, such that a greater decrease in overall running speed was observed when going from 55 to 75 years than from 35 years to 55 years ($P < 0.05$). As illustrated in Panel C, CS exhibited a non-linear,

inverse relationship with age ($R^2=0.65-0.78, P<0.001$) with the rate of decline of CS steepening after ~55 years. Age was weakly related to D' ($R^2=0.06, P=0.035-0.055$), with an average of a 1.08-1.46 meter decline in D' per year.

CONCLUSIONS: Even in subjects representing some of the fittest individuals in the world for a given age, the speed-distance relationship and CS are impacted in a non-linear manner by age, with steeper declines in CS being observed after age ~55 years.

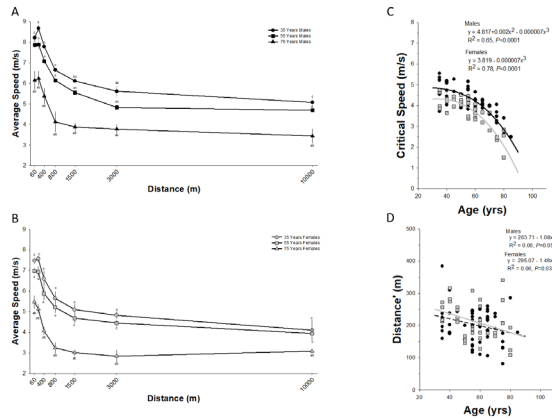

Figure 1: The Impact of Age on the Relationship between Average Race Speed and Race Distance (Panels A and B), Critical Speed (Panel C) and Distance' (Panel D). Black filled circles represent data from males. Gray filled circles represent data from females. a: significantly different from same distance at 35 years. b: significantly different from same distance at 55 years. c: significantly different from same distance at 75 years.

their higher risk for hypertension. It is unknown whether AA and Caucasian Americans (CA) would exhibit different blood pressures following acute bouts of anaerobic exercise.

PURPOSE: To assess hemodynamic changes in healthy, young AA and CA women following repeated bouts (two) of maximal anaerobic exercise. **METHODS:** Eight young, healthy AA women and 9 CA women completed this study. Vascular and hemodynamic measurements were taken at rest, and 5 (P5-1st), 15 (P15-1st), and 30 minutes (P30-1st) following a maximal anaerobic exercise test on cycle ergometer, and 5 (P5-2nd), 15 (P15-2nd), and 30 (P30-2nd) minutes following the second maximal anaerobic exercise test. Brachial systolic (SBP), diastolic (DBP) blood pressures, central aortic SBP, DBP and mean arterial blood pressure (aortic MAP) were measured. Carotid arterial stiffness (beta-stiffness index) were obtained using ultrasonography. **RESULTS:** Data were presented in Table 1 as mean \pm standard error. Resting DBP and aortic DBP were significantly different between AA and CA ($p<0.05$). There was a significant race by time interaction for aortic MAP ($* p<0.05$). And there was a trend towards significance in race by time interaction for beta stiffness index ($p=0.06$). **CONCLUSION:** Acute bouts of anaerobic exercise increase aortic MAP in young AA but not in CA, and it may be related to increases in arterial stiffness in AA. The heightened BP and vascular responses to exercise stimulus may play a role in the pathogenesis of hypertension in AA.

Hemodynamics Between Post-exercise Hypotension Responders And Non-responders After Maximal Exercise

Yu-Ching Wang¹, Lin-Sheng Lin¹, Hao-Min Cheng², Hsin-Fu Lin¹. ¹National Taiwan University, Taipei, Taiwan. ²Taipei Veterans General Hospital, Taipei, Taiwan.
Email: r06h42021@ntu.edu.tw

(No relevant relationships reported)

Emerging evidence showed hemodynamic indices derived from arterial waveform predict cardiovascular events and target organ damage. Whether these biomechanical markers change correspondently with post-exercise hypotension (PEH) remain unknown.

PURPOSE: To test the hypothesis that arterial hemodynamic indices following a maximal exercise test in PEH responders would differ from those in non-responders.

METHODS: A total of 71 recreational active young people (age=23.1 \pm 3.8yrs; BMI=23.1 \pm 3.1kg/m²) were recruited and underwent an acute bout of graded maximal exercise. Blood pressure (BP), arterial stiffness, and hemodynamics were measured at baseline, 5-, 15- and 30-min after exercise. Data analysis was compared between PEH responders (reduced brachial systolic or diastolic BP within 30 mins) and non-responders.

RESULTS: There were 43 responders (M/F=18/25) and 28 non-responders (M/F=10/18). The changes of brachial systolic BP, diastolic BP, and central systolic BP in responders were greater than those in non-responders throughout different time points following exercise. There was no group difference on conventional blood biomarkers, brachial-ankle pulse wave velocity, augmentation index, backward pressure, and reservoir pressure integral. Responders had a greater reduction on excessive pressure integral (XSPI) at 5 min post exercise. Overall arterial reservoir indices correlated better with the PEH changes compared to wave reflection indices.

CONCLUSIONS: From arterial hemodynamic perspective, the reduction of XSPI appeared the most pronounced biomechanical marker associated with post-exercise hypotension.

Muscle Damage And Acute Kidney Injury In Endurance Mountain Running

Daniel Rojas-Valverde¹, Braulio Sanchez-Ureña¹, Guillermo Olcina², Jose Pino-Ortega³, Randall Gutierrez-Vargas¹, Rafael Timón⁴, Jeffrey M. Mjaanes, FACSM⁵. ¹National University, Heredia, Costa Rica. ²University of Extremadura, Cáceres, Spain. ³University of Murcia, Murcia, Spain. ⁴University of Extremadura, Cáceres, Spain. ⁵Northwestern University, Evanston, IL. (Sponsor: Jeffrey M. Mjaanes, FACSM)
Email: drojasv@hotmail.com

(No relevant relationships reported)

During mountain running events, athletes can experience muscular impairment as well as adverse health conditions of cardiovascular, immunological, renal and hepatic nature. Specifically, regarding the renal system, it has been shown that physical stress is a factor that contributes to the transitory decrease of renal function known as acute kidney injury (AKI) and muscle disintegration called exertional rhabdomyolysis (ER). The aim of this study was to assess hydration status, kidney function and muscle damage during an endurance mountain running (35.3km trail run, total positive ascend 1815m). A total of 26 experienced and trained mountain runners (age 39.5 \pm 9.23 years, weight 71.26 \pm 11.17 kg, height 171.65 \pm 8.69 cm) took part of the study. Assessments included urine specific gravity (USG), body weight (BW), creatinine (Cr), blood ureic nitrogen (BUN), albumin (ALB), glomerular filtration rate (eGFR) and creatine kinase

(CK), at three distinct moments (pre, post_{0h} and post_{24h}). A repeated measures analysis of variance (ANOVA) was used to verify possible differences between measurement times. There were no differences in USG ($F_{(2,34)} = 0.817$, $p = 0.45$, $\omega_p^2 = 0.01$), however differences were noted in BW ($F_{(1,26)} = 5.37$, $p = 0.029$, $\omega_p^2 = 0.16$, pre > post_{0h}), Cr ($F_{(2,42)} = 34.453$, $p < 0.01$, $\omega_p^2 = 0.6$, pre < post_{24h} < post_{0h}), BUN ($F_{(2,42)} = 15.694$, $p < 0.01$, $\omega_p^2 = 0.39$, pre < post_{0h} < post_{24h}), ALB ($F_{(1,26)} = 7.806$, $p < 0.01$, $\omega_p^2 = 0.2$, pre < post_{24h} < post_{0h}), eGFR ($F_{(1,26)} = 5.403$, $p < 0.01$, $\omega_p^2 = 0.15$, post_{0h} < post_{24h} < pre) and CK ($F_{(1,26)} = 18.957$, $p < 0.01$, $\omega_p^2 = 0.43$, pre < post_{24h} < post_{0h}). Along with a decrease in body weight (BW loss > 2%), a decrease in eGFR and a rise in ALB, BUN, CK and AKI was found (acute absolute Cr difference > 0.3 mg/dL). This constellation of values supports the idea that endurance mountain running can lead to AKI and muscle injury because of mechanical damage of both kidney and muscle due to repeated effort.

Heavy Battle Rope Exercise On Autonomic Modulation: Differences Between The Sexes

Meredith C. Paskert, Sarah G. Kearney, Jason C. Parks, Erica M. Marshall, Stacie M. Humm, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*

Email: mpaskert@kent.edu

(No relevant relationships reported)

Heavy rope battle exercise (HI-HRE) is used to increase power, muscle hypertrophy and maximal strength. The data regarding autonomic modulation in response to heavy battle rope exercise between the sexes are non-existent. **PURPOSE:** To assess sex differences in autonomic modulation in response to heavy battle rope exercise. **METHODS:** Twenty-six (men: 14; women: 12) resistance-trained individuals volunteered for the study. Heart rate (HR), vagal modulation, and sympathovagal dominance, collected via heart rate variability, were measured at Rest, 15 (Rec1), 30 (Rec2), and 60 (Rec3) minutes after the heavy rope battle exercise. Measures of vagal tone included logarithmically (ln) transformed high-frequency power (lnHF), and the root mean square of successive differences (lnRMSSD). Sympathovagal dominance was assessed using logarithmically (ln) transformed low frequency/high frequency ratio (lnLF/HF). The acute HI-HRE consisted of six, 15-second exercise bouts, using a double wave pattern at 180bpm, separated by 30-seconds of passive recovery intervals. Two-way repeated measures analysis of variance were used to evaluate differences between the sexes (men, women) across the repeated factor of time (Rest, Rec1, Rec2, and Rec3). **RESULTS:** There were no significant two-way interactions (sex by time) for any variable. However, HR demonstrated a significant main effect of time (Rest: 62±10bpm; Rec1: 84±10bpm; Rec2: 76±9bpm; Rec3: 70±8bpm; $p \leq 0.001$) in that each time all three recovery measurements were augmented compared to Rest. There were also significant main effects of time for lnHF (Rest: 7.51±1.09 ms²; Rec1: 4.62±1.30 ms²; Rec2: 5.35±1.20 ms²; Rec3: 6.29±0.97 ms², $p \leq 0.001$) and lnRMSSD (Rest: 4.23±0.63ms; Rec1: 2.71±0.65ms; Rec2: 3.10±0.60ms; Rec3: 3.57±0.51ms, $p \leq 0.001$) in which all three recovery measurements were attenuated compared to Rest. A significant main effect of time was also noted for lnLF/HF (Rest: 0.87±0.11; Rec1: 1.19±0.21; Rec2: 1.14±0.30; Rec3: 1.03±0.15, $p \leq 0.001$) in which all values during recovery were significantly elevated compared to Rest. **CONCLUSIONS:** These data demonstrate that both men and women have the same responses in HR and autonomic modulation during recovery from acute HI-HRE. Collectively, all measures failed to return to resting values within 60 minutes.

2599 Board #60 May 29 10:30 AM - 12:00 PM
Pulse Wave Reflection After Upper-body Resistance Exercise With And Without Blood Flow Restriction Between Sexes

Yu Lun Tai¹, Erica M. Marshall², Jason C. Parks², J. Derek Kingsley, FACSM². ¹University of Texas Rio Grande Valley, Brownsville, TX. ²Kent State University, Kent, OH.

(No relevant relationships reported)

Acute upper-body resistance exercise (URE) with blood flow restriction (BFR) on pulse wave reflection (PWR) between sexes is unclear. **PURPOSE:** To evaluate the effects of URE, with and without BFR, on PWR between sexes. **METHODS:** Nine women and 14 men volunteered for the study (Mean±SD: Age, 22±2 yrs). Hemodynamics and PWR were assessed at rest (R), and at 10 (R10), 25 (R25), 40 (R40), and 55 (R55) minutes after either URE (lat pulldown and chest press) with or without BFR. The BFR condition consisted of 4 sets of 30, 15, 15, and 15 repetitions with 30% 1-repetition maximum (1RM), while the without BFR (high-load, HL) condition consisted of 4 sets of 8 repetitions at 70% 1RM. A 2x2x5 repeated measures ANOVA was used to evaluate the effect of sexes across conditions and time. **RESULTS:** There were no significant 3-way interactions. There were main effects of time for mean arterial pressure (MAP) and central MAP (cMAP). MAP (BFR, Women vs. Men, R: 80±6 vs. 84±4mmHg, R10: 75±6 vs. 78±6mmHg, R25: 79±5 vs. 81±6mmHg; HL, R: 79±5 vs. 84±7mmHg, R10: 77±4 vs. 81±5mmHg, R25: 77±4 vs. 83±5mmHg, $p = 0.001$) decreased at R10 compared to rest and returned to resting level at R25, while cMAP (BFR, Women vs. Men, R40: 77±5 vs. 78±6mmHg, R55: 78±5 vs. 80±7mmHg;

HL, R40: 77±7 vs. 79±6mmHg, R55: 79±5 vs. 82±7mmHg, $p = 0.038$) increased at R55 compared to R40. There were sexes difference for MAP for the HL (Women vs. Men, R: 79±5 vs. 84±7mmHg, R10: 77±4 vs. 81±5mmHg, R25: 77±4 vs. 83±5mmHg, R40: 77±5 vs. 82±6mmHg, R55: 79±5 vs. 85±6mmHg, $p < 0.05$) condition such that women had lower MAP compared to men at all-time points. There were significant sex by time differences for heart rate (HR), augmentation index (AIx), and AIx normalized to 75bpm (AIx@75) such that women had higher HR at rest (Women: 65±3bpm, Men: 54±2bpm, $p < 0.001$), AIx (Women: 17.2±3%, Men: 10.7±2.3%, $p = 0.002$), and AIx@75 (Women: 12.3±3.3%, Men: 0.5±2.7%, $p < 0.001$) compared to men at rest and R10. **CONCLUSION:** These data suggest that sex difference existed for HR and PWR at rest, and men had greater responses to URE with and without BFR compared to women. Although both sexes had attenuated recovery for PWR in response to URE without BFR, PWR returned to resting levels in both sexes 40 minutes after URE with or without BFR.

2600 Board #61 May 29 10:30 AM - 12:00 PM
Foam Rolling And Hrv

Thomas Kopec, Rebecca Rogers. *Samford University, Birmingham, AL.* (Sponsor: John Petrella, FACSM)

Email: kopec001@gmail.com

(No relevant relationships reported)

PURPOSE: The purpose of this study was to determine if a bout of foam rolling could increase parasympathetic activity as measured by heart rate variability (HRV). This study utilized an ultra-short-term HRV finger sensor device and software that records the root mean square sum of standard deviations with the natural log transformation multiplied by 20 (HRV) for easy interpretation of the results.

METHODS: Twenty (20) participants were measured pre-activity for HRV using the finger sensor connected to a tablet while lying supine, and then a second measure was recorded with them sitting upright with feet on the ground. The software collects HRV values in 55 seconds, and directs their breathing with an on-screen prompt. Participants then oscillated on a closed-cell cylindrical foam roller using their body weight on the triceps surae, hamstrings, quadriceps, lumbar spine, and pectoral muscles, respectively, for 60 seconds. Participants first massaged the right limb and then repeated the same muscle group on the left before continuing to the next region. A second HRV measurement was recorded with the same procedures.

RESULTS: Paired samples t-tests revealed no difference between supine measures ($p = 0.56$), nor the seated measures ($p = 0.59$). There was no difference between sexes.

CONCLUSIONS: The single bout of foam rolling across major muscle groups do not increase parasympathetic activity via venous return as hypothesized. The change in HRV values averaged 1.55 and 1.30 decreases between supine and seated, respectively, but those changes are not statistically significant. The task of self-massage may be more metabolically demanding than initially believed, as the required muscle activation overpowers the venous return from massage. More research is needed to determine if passive massage would produce the desired parasympathetic neural increase.

2601 Board #62 May 29 10:30 AM - 12:00 PM
Cool-down Versus Passive Recovery After Supramaximal Interval Exercise On Hemodynamics And Aortic Stiffness

Jason C. Parks, Erica M. Marshall, Stacie M. Humm, Emily K. Erb, Meredith C. Paskert, Sarah G. Kearney, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*

(No relevant relationships reported)

PURPOSE: To compare the effects of a cool-down (CD) versus passive recovery (PR) after supramaximal interval exercise on hemodynamics and aortic stiffness. **METHODS:** Twelve moderately active individuals (Mean±SD: 23±3 yrs (Men: n=8; Women: n=4) were assessed for hemodynamics and aortic stiffness at Rest, and 15 (R15), 30 (R30), 45 (R45) and 60 (R60) minutes following supramaximal interval exercise. Hemodynamics, via photoplethysmography, included heart rate (HR), mean arterial pressure (MAP), cardiac output (CO), stroke volume (SV), and total peripheral resistance (TPR). Aortic stiffness was measured via pulse wave velocity (PWV). Two-way repeated ANOVAs were used to evaluate the main effects of condition (CD, PR) across time (Rest, and R15, R30, R45 and R60). **RESULTS:** There were no significant condition by time interactions. There were significant ($p \leq 0.001$) main effects of time for HR, CO, SV and TPR such that both conditions responded similarly. HR was elevated at all recovery times compared to Rest (CD: Rest: 59±5bpm; R15: 91±10bpm; R30: 84±15bpm; R45: 74±10bpm; R60: 71±9bpm; PR: Rest: 59±7bpm; R15: 90±10bpm; R30: 80±11bpm; R45: 74±9bpm; R60: 71±11bpm). CO was elevated at R15 compared to Rest (CD: Rest: 5.4±0.9L/min; R15: 8.5±1.8L/min; PR: Rest: 5.8±0.9L/min; R15: 9.4±2.0L/min), with values that returned to Rest by R30. SV was similar to Rest at R15 and R30, and significantly higher at R15 compared to R30, R45 and R60. However, R45 and R60 were attenuated compared to Rest (CD: Rest 92.0±14.5mL/b; R15: 100.5±20.1mL/b; R30: 84.7±16.8mL/b; R45: 79.0±13.7mL/b; R60: 78.6±12.1mL/b; PR: Rest: 96.0±11.6mL/b; R15: 102.9±19.5mL/b; R30:

82.4±17.3mL/b; R45: 79.4±14.8mL/b; R60: 76.1±16.4mL/b). TPR was attenuated at R15 after supramaximal interval exercise compared to Rest (CD: Rest: 0.9±0.2mmHg/mL/min; R15: 0.5±0.1mmHg/mL/min; PR: Rest: 0.9±0.1mmHg/mL/min; R15: 0.5±0.1mmHg/mL/min), such that it decreased in both conditions, before it returned to Rest by R30. The supramaximal interval exercise had no effect on MAP or PWV. **CONCLUSIONS:** Collectively, these data suggest that a proper cool-down does not elicit a means to attenuate transient changes in hemodynamics after supramaximal exercise in moderately-trained individuals.

Sex Differences In Arterial Stiffness Following Acute Resistance Exercise

Rebecca M. Kappus, Elise M. Witwer, Kaitlin McShea, Caroline Rushing. *Appalachian State University, Boone, NC.* (Sponsor: Rebecca Battista, FACSM)

(No relevant relationships reported)

During resistance exercise there is an increase in blood pressure, with systolic pressure rising up to 400 mmHg. This transient elevation in pressure has been shown to result in acutely stiffer vessels in young males, however, this has not been well studied in young females. It is possible that the sex hormones of young females may be protective against this pressure load, resulting in differential responses following resistance exercise. **PURPOSE:** The purpose of this study was to determine if there are sex differences in arterial stiffness following an acute resistance exercise bout in young, healthy males and females who are not currently resistance training. **METHODS:** Carotid beta stiffness (β), arterial compliance (AC), and elastic modulus (Ep) measurements were taken in 23 young participants (10 males, 13 females; 26 ± 1 years) before, immediately after, and 30 minutes following full body resistance exercise. Exercise consisted of 2 sets of 10-12 repetitions performed on 8 resistance machines completed at 40% 1RM for the upper body and 60% 1RM for the lower body. Females were tested during the early follicular phase of their menstrual cycle to control for sex hormones. Exercise values (pre, post, post30) were compared between sexes using a repeated measures ANOVA, with significance set at $p < 0.05$. When the interaction was significant, the responses were evaluated with paired samples t-tests within each sex and independent t-tests between sexes. **RESULTS:** There were no sex differences in stiffness values prior to exercise, but males displayed significantly higher β and Ep and lower AC post and post30 compared to females. Males demonstrated significant increases in β (4.2 ± 0.4 to 6.6 ± 0.5 to 5.8 ± 0.5 AU) and Ep (48 ± 5 to 73 ± 6 to 65 ± 6 kPa) and decreases in AC (1.5 ± 0.2 to 0.9 ± 0.1 to 1.1 ± 0.1 mm²/kPa) both immediately and 30 min post resistance exercise compared to baseline values, while females had no change in AC (1.4 ± 0.1 to 1.2 ± 0.1 to 1.5 ± 0.1 mm²/kPa) or Ep (46 ± 4 to 52 ± 5 to 44 ± 5 kPa) with exercise and an immediate increase in β that returned to baseline at 30 min post (4.2 ± 0.3 to 5.1 ± 0.5 to 4.3 ± 0.4 AU). **CONCLUSION:** Acute resistance exercise in females does not result in the elevation of stiffness as seen in males. It appears females may be protected from this increased pressure load, which may be due to the vasodilatory effects of estrogen.

Bilateral And Unilateral Resistance Exercise On Pulse Wave Reflection And Arterial Stiffness

Erica M. Marshall, Jason C. Parks, Stacie M. Humm, Emily K. Erb, Meredith C. Paskert, Sarah G. Kearney, J. Derek Kingsley, FACSM. *Kent State University, Kent, OH.*

Email: emarsh14@kent.edu

(No relevant relationships reported)

PURPOSE: To examine changes in pulse wave reflection and arterial stiffness following bilateral (BL) and unilateral (UL) resistance exercise (RE). **METHODS:** Seventeen individuals (Mean±SD: 23 ±3yrs) were assessed for measures of hemodynamics, pulse wave reflection and arterial stiffness at Rest as well as 10, and 30 minutes post-exercise. Two-way repeated measures ANOVAs were used to analyze the effects of RE condition (BL, UL) across time (Rest, 10, 30 minutes). **RESULTS:** While there were no significant interactions, there were significant main effects of time for brachial diastolic blood pressure (BDBP), central diastolic blood pressure (CDBP), augmentation index (AIx), augmentation index at 75bpm (AIx@75), subendocardial viability ratio (SEVR), and pulse wave velocity (PWV). There were no significant main effects for brachial or central systolic blood pressure. BDBP (BL: Rest: 65 ±5mmHg, Rec1: 61±5mmHg, Rec2: 63 ±3mmHg; UL: Rest: 68 ±5mmHg, Rec1: 64 ±7mmHg, Rec2: 66 ±5mmHg, $p = 0.009$) was decreased at 10 and 30 minutes compared to rest following BL. Following UL, BDBP was decreased only at 30 minutes. CDBP (BL: Rest: 65 ±5mmHg, Rec1: 62 ±5mmHg, Rec2: 64±3mmHg, UL: Rest: 69 ±5mmHg, Rec1: 65 ±7mmHg, Rec2: 66 ±5mmHg, $p = 0.009$) was decreased at 10 minutes compared to Rest, and recovered by 30 minutes for BL. Following UL, CDBP was decreased at 10 and 30 minutes compared to Rest. AIx (BL: Rest: 11.6 ±8.4%, Rec1: 23.5 ±15.2%, Rec2: 18.6 ±12.5%; UL: Rest: 11.9 ±6.8%, Rec1: 25.1 ±13.4%, Rec2: 14.9 ±9.4%, $p < 0.001$) and AIx@75 (BL: Rest: 3.6 ±10.4%, Rec1: 22.1 ±15.9%, Rec2: 8.8 ±12.5%; UL: Rest: 4.1 ±7.9%, Rec1: 24.5 ±15.1%, Rec2: 11.2

±13%, $p < 0.001$) increased at 10 and 30 minutes compared to Rest following BL. Following UL, AIx was increased at 10 minutes compared to Rest and recovered by 30 minutes. AIx@75 also increased at 10 minutes but did not recover at 30 minutes for UL. For both conditions, SEVR ($p < 0.001$) decreased at 10 and 30 minutes compared to Rest. PWV ($p = 0.003$) increased at 10 minutes compared to Rest and returned to Rest by 30 minutes for both conditions. **CONCLUSIONS:** Our data suggest that unilateral RE may produce a quicker recovery in terms of central diastolic BP and AIx, thereby returning measures of pulse wave reflection to rest at a faster pace than bilateral RE.

2604 Board #65 May 29 10:30 AM - 12:00 PM
Orthostatic Challenge After High-intensity Interval Exercise Vs. Continuous Aerobic Exercise In Young Women

Jitanan Laosiripisan¹, Napasakorn Chuensiri², Kadidesh Chomkum¹, Suwijak Boonpratheep¹. ¹*Thammasat University, Pathum Thane, Thailand.* ²*Chulalongkorn University, Bangkok, Thailand.* (Sponsor: Hirofumi Tanaka, FACSM)

Email: jitanan.l@allied.tu.ac.th

(No relevant relationships reported)

Background: Orthostatic intolerance is one of the most common blood pressure regulation disorders and is highly prevalent and more common in young women. Young women tend to experience symptoms such as dizziness and fainting earlier and more often during the orthostatic stress. This tendency may be exacerbated after exercise when the phenomenon of post-exercise hypotension was superimposed. **Purpose:** This study aimed to investigate acute effects of two commonly performed exercises (high-intensity interval exercise and continuous aerobic exercise) on orthostatic responses after exercise in young women. **Methods:** Twenty apparently healthy young women aged 18-35 years were studied. Assessment of peak oxygen consumption ($VO_{2\text{peak}}$) was performed in the first visit. Each participant performed high-intensity interval exercise (HIIE) or continuous aerobic exercise (CAE) for 40 minutes each in a separate day. HIIE was performed at 80-90% of $VO_{2\text{peak}}$ (exercise:rest = 1:2). CAE was performed at 50-60% of $VO_{2\text{peak}}$. Orthostatic challenge tests (i.e., rapid standing from the supine position) were performed before and at 0, 60, and 120 minutes after the exercise session was completed. **Results:** Heart rate responses to the orthostatic stress were not different between the HIIE and CAE sessions. Both modes of exercise induced reductions in systolic blood pressure reductions after exercise. However, the magnitude of systolic blood pressure reduction during the orthostatic challenge was greater after the HIIE session (-13 ± 6 mmHg) than the CAE session (-8 ± 7 mmHg). **Conclusion:** These results suggest that compared with CAE, HIIE induced a greater reduction in systolic blood pressure during the orthostatic challenge and could make young women more prone to orthostatic intolerance.

Sex Differences In Circulating Angiogenic Cells And Circulating Endothelial Cells In Response To Acute Exercise

Rian Landers-Ramos¹, Ian Imery², Dakota Siok¹, Urvi Patel¹, Sarah Syme¹, Kailyn Gates¹, Elizabeth Boyle¹, Elizabeth Dalton¹, Kathleen Dondero¹. ¹*Towson University, Towson, MD.* ²*Johns Hopkins University, Baltimore, MD.*

Email: rlandersramos@towson.edu

(No relevant relationships reported)

Acute exercise provides a stimulus for improving the function and health of the endothelium by initiating release of circulating angiogenic cells (CACs). However, this may also result in endothelial stress through the shedding of endothelial cells into circulation (CECs). The ratio of CACs/CECs may serve as a unique indicator of vascular health but sex differences in the ratio of CACs/CECs in response to acute aerobic exercise are unknown. **PURPOSE:** To determine whether there are sex differences in the CAC and CEC response to a single bout of submaximal treadmill exercise. **METHODS:** Subjects were healthy physically active men (n=15) and women (n=10) between the ages of 18-29 years. Maximal oxygen consumption ($VO_{2\text{max}}$) was assessed and 48 hours later, participants performed 30 minutes of treadmill running at 70% $VO_{2\text{max}}$. Fasted blood was obtained before and 30-minutes after the treadmill exercise. Peripheral blood mononuclear cells were isolated, FeR blocked and immunostained with antibodies specific to CD34-FITC, KDR-PE, CD31-FITC, CD3-APC, CD146-PECy7 and CD45-PerCP, and fixed in paraformaldehyde. The forward-side-scatter plot was used to identify the lymphocyte and monocyte gates from a total of 5,000 events/sample using a flow cytometer. CACs (CD34+/KDR+, CD31dim, and CD31dim/CD3+) and CECs (CD146+/CD45-) were quantified. **RESULTS:** There was no main effect for exercise or sex, or a sex*exercise interaction in the number of CD34+/KDR+ and CD31dim cells ($P > 0.05$ for both). There was no main effect of exercise in CD31dim/CD3+ cells but there was a significant main effect of sex ($P = 0.038$) and a trend for a sex*exercise interaction ($P = 0.069$) in men exhibiting 8% and 3% fewer CD31dim/CD3+ cells vs. women before and after exercise, respectively. Regardless of sex, CECs increased from 45.2 ± 9.7 events to

66.7 ± 18.7 events after the acute exercise bout ($P=0.027$). There was no main effect for exercise or sex, or a sex*exercise interaction in CAC/CEC ratios ($P>0.05$ for all). **CONCLUSIONS:** Regardless of sex, the lack of mobilization of CACs in response to submaximal treadmill exercise suggests that other repair mechanisms may play a stronger role in maintaining the balance between endothelial repair and disturbance in younger physically active adults.

Effects Of Acute Short Sleep And High-intensity Interval Exercise On Heart Rate Variability Frequency Indices

Zacharias Papadakis¹, Jeffrey S. Forsse², Matthew N. Peterson².
¹Barry University, Miami Shores, FL. ²Baylor University, Waco, TX.
 Email: zpapadakis@barry.edu
 (No relevant relationships reported)

Short sleep (SS) disrupts the normal functioning of the autonomic nervous system (ANS). Heart rate variability (HRV) is a reproducible measure of ANS function. Reduction in HRV represents a disruption of the ANS. High-intensity interval exercise (HIIE) reduces HRV. The immediate HRV response and its short-term recovery after HIIE is unexplored. SS prior to HIIE may disrupt further the ANS and reduce HRV. **PURPOSE:** To characterize the influence of SS on HRV after a single bout of HIIE in the hours post-exercise (PE). **METHODS:** Fifteen physically active males (age 31.1±5.3 yr) with good sleep quality as determined by the Pittsburgh Sleep Quality Index (PSQI) participated in this study. Participants completed a non-exercise control trial after 9 to 9.5 hrs of reference sleep (RS), a HIIE treadmill running (90% and 40% of $VO_{2\text{reserve}}$ in 3:2 min ratio) to expend 500 kcals after reference sleep (RSX) and after 3 to 3.5 hrs of SS (SSX) in a randomized crossover design. After being in a supine position for 10 minutes in a quiet and temperature-controlled environment heart rate (HR) was recorded for 5 minutes the night before, the morning of the next day, 1-, 2-, 4- and 6-hours PE using an elastic electrode belt (Polar Wearlink®). Sleep was performed at their own residence. Supine resting HRV indices (frequency domain: LF/HF and VLF) obtained from HR were measured and processed by CardioMood®. Data were analyzed using a 3 (condition) by 6 (time) repeated measures ANOVA. Examined variables violated normality and thus were transformed into natural logarithm (ln). Bonferroni was used for post hoc comparisons. Significance was set at $p < 0.05$. All analyses were performed using SPSS®. **RESULTS:** For ln VLF there was a main effect for condition by time interaction ($F_{10,140}=3.60, p=.000, \eta^2=.204$), but not for ln LF/HF condition by time ($F_{10,140}=1.84, p=.060, \eta^2=.116$). In VLF was both decreased in RSX at 1hr PE (6.3±2.5, $p=.001$) and 2hr PE (7.1±2.0, $p=.007$) and in SSX 1hr PE (6.1±2.2, $p=.000$) and 2hr PE (7.4±2.6, $p=.000$) compared to RS. During *post hoc* analysis frequency domain ln LF/HF was increased in SSX at Day 2-baseline (.29±.17, $p=.040$) and at 1hr PE (1.1±.19, $p=.041$). **CONCLUSION:** HIIE with 3:2 min ratio decreases HRV for up to 2 hours PE and takes more than 6 hours to return to baseline levels. These responses are not modified by a single night of short sleep.

Differential Apelin Responses To Physical Stress In Elite Hungarian Athletes

Roland Ligetvári¹, Pongrác Ács¹, Gabriella Far¹, Ákos Móra¹, Éva Csöndör¹, Zsolt Komka², István Szokodi¹, Miklós Tóth¹, Tímea Stromájer-Rácz¹, József Betlehem¹, András Oláh¹.
¹University of Pécs, Hungary, Pécs, Hungary. ²Semmelweis University, Hungary, Budapest, Hungary.
 Email: roland.ligetvari@gmail.com
 (No relevant relationships reported)

PURPOSE: To characterize the changes of different fragments of the strong positive inotropic peptide Apelin (AP) upon extreme physical stress in Hungarian handball players. The 77-amino acid preproapelin is cleaved to shorter active peptides, such as AP-36 and AP-13. However, these Apelin receptor agonists may differ in biological efficacy, with the shorter fragments being more potent. **METHODS:** We investigated the response of male athletes ($n=54$; age=24±2) to extreme physical (vita maxima treadmill test) stress. Cardiovascular, metabolic and respiratory parameters were monitored. All parameters were measured at baseline, at maximal stress situation and 30 minutes in the restitution phase. Circulating peptide (AP-13, AP-36, NT-proBNP) levels were measured by ELISA. **RESULTS:** AP-13 levels increased significantly at the peak of the treadmill test (167±71.5 pg/ml), compared to baseline values (144±72.4 pg/ml; $p<0.05$). After 30 minutes of recovery, AP-13 levels decreased significantly (137±65.7 pg/ml; $p<0.001$) returning to the baseline levels ($p=NS$). AP-36 showed a more robust increase in response to the maximal intensity treadmill test (80.7±61.4 pg/ml vs. 159±81.8 pg/ml; $p<0.001$), which decreased below the control levels after 30 minutes of restitution (52.4±23.2 pg/ml; $p<0.001$). NT-proBNP levels remained unchanged in all settings. Importantly, baseline and peak AP-13 levels showed a negative correlation with AP-36 response to the treadmill test ($r=-0.400, p<0.05$; $r=-0.416, p<0.05$; respectively). The

change in AP-13 level upon extreme physical stimulation correlated with the maximal MET ($r=0.374, p<0.05$) and the relative $VO_{2\text{max}}$ ($r=0.340, p<0.05$). Our subjects showed differential AP response: 62% of the individuals showed elevated whereas 38% lower AP-13 levels after the treadmill test. AP-36 increased in 85% and decreased in 15% of the athletes at peak intensity.

CONCLUSION: Collectively, our data show that both Apelin fragments change significantly after a vita maxima treadmill test, suggesting that Apelin as an endogenous positive inotropic peptide may contribute to the stress adaptation of the heart. Athletes having higher baseline and peak AP-13 plasma concentrations had a lower AP-36 response, suggesting the existence of a previously unknown interplay between the distinct fragments.

Dose Smoking Immediately After Exercise Deteriorate Hemodynamic And Autonomic Recovery?

Minjeong Cho, Ingo Park, Youngwoo Kim, Hyunjeong Kim, Saeyoung Jae. University of Seoul, Seoul, Korea, Republic of.
 (No relevant relationships reported)

Although regular exercise reduces the risk of cardiovascular diseases, post-exercise recovery is thought to be a vulnerable phase for an increased susceptibility to sudden cardiovascular events. Cigarette smoking has been demonstrated to amplify sympathetic activation and cardiovascular stress. Paradoxically, many smokers tend to smoke immediately after leisure-time physical activity or exercise. **PURPOSE:** We tested the hypothesis that smoking immediately after exercise would deteriorate autonomic and hemodynamic recovery following an acute bout of aerobic exercise compared with the sham smoking control. **METHODS:** Ten healthy male smokers (age=21±3yrs; BMI=24.7±3.9kg/m²) participated in two trials in a randomized order: 1)cigarette smoking immediately after exercise (SM), 2)sham cigarette smoking after exercise (SHAM). All subjects exercised on a treadmill at a moderate intensity (40-60% of heart rate reserve) for 30 minutes and smoked one cigarette (0.6mg nicotine) or sham cigarette immediately after exercise. We measured heart rate, brachial and central artery blood pressures, rate-pressure product, carotid-femoral pulse wave velocity (PWV), brachial artery flow-mediated dilation (FMD), and heart rate variability time domains. All variables were measured at baseline and at 10 minutes and 30 minutes after exercise, except for FMD measured at baseline and 30 minutes after exercise. **RESULTS:** Rate-pressure product was significantly higher in the SM trial compared to the SHAM trial (interaction effect; $p=0.008$). Central systolic and diastolic blood pressure increased in the SM trial (interaction effect; $p=0.026, p=0.006$, respectively). PWV was higher post-exercise in the SM trial, but this did not reach statistical significance ($p=0.116$). FMD increased only in the SHAM trial ($p=0.008$). SDNN decreased from baseline more so in the SM trial (SM:51.5±24.5ms to 23.6±15.7ms to 36.3±18.9ms) compared with the SHAM trial (SHAM:56.8±28.1ms to 43.1±17.2ms to 50.8±22.8ms) ($p=0.041$ for interaction). **CONCLUSION:** Cigarette smoking immediately after exercise deteriorated autonomic and hemodynamic recovery in smokers, suggesting that smoking immediately after leisure-time physical activity or exercise should be avoided to reduce in the susceptibility of sudden cardiovascular events.

Postexercise Hypotension, Aortic Pressure And Autonomic Modulation In Men Living With HIV

Juliana P. Borges, Juliana P. Barros, Marcus Vinicius dos S Rangel, Wallace Monteiro, Felipe Amorim, Tainah de Paula, Paulo Farinatti. University of Rio de Janeiro State, Rio de Janeiro, Brazil.
 Email: julipborges@gmail.com
 (No relevant relationships reported)

A single session of aerobic exercise reduces blood pressure vs. pre-exercise, which is referred as postexercise hypotension (PEH). Changes in cardiac autonomic control and local vasodilatation contribute to PEH. HIV-infected patients present higher risk of hypertension, autonomic and endothelial dysfunction, which may influence the PEH. However, this phenomenon has never been studied in this population. **PURPOSE:** To investigate the effects of acute aerobic exercise upon systemic blood pressure, aortic pressure, and cardiac autonomic modulation in men living with HIV. **METHODS:** After cardiopulmonary exercise testing, 10 HIV-infected (HIV: 47.5 ± 9.7 yrs; 25.2 ± 3.0 kg.m⁻²) and 14 healthy men (CTL: 40.1 ± 10.5 yrs; 25.8 ± 3.4 kg.m⁻²) underwent cycling bouts expending 150 kcal at 50% oxygen uptake reserve (time to achieve 150 kcal - HIV: 24.1 ± 5.5 and CTL: 23.1 ± 3.0 min) and control sessions (20 min), in a randomized counterbalanced order. Systolic blood pressure (SBP), aortic pressure, and heart rate variability were assessed 30 min before and 60 min after each session, by means of oscillometric digital monitor, pulse wave reflection (tonometry), and beat-to-beat heart rate intervals, respectively. Comparisons within-between sessions were made using 2-way ANOVA with repeated measures ($P \leq 0.05$). **RESULTS:** No difference was detected between groups for maximal oxygen uptake (HIV: 27.3 ± 4.2 vs. CTL: 31.4 ± 6.8 mL.kg⁻¹.min⁻¹; $P=0.1$) and SBP at rest (HIV: 117.2 ± 11.6 vs. CTL: 112.2 ±

8.9 vs mmHg; $P=0.2$). Resting aortic pressure was higher in HIV (107.0 ± 9.3 mmHg) vs. CTL (100.0 ± 4.3 mmHg; $P=0.03$), while standard deviation of NN intervals (SDNN) was lower in HIV (28.3 ± 11.2 ms) vs. CTL (43.9 ± 20.8 ms; $P=0.04$). In CTL, SBP (-9.3 ± 5.9 mmHg; $P=0.01$), aortic pressure (-6.3 ± 4.6 mmHg; $P=0.03$), and SDNN (-23.4 ± 44.5 ms; $P=0.05$) decreased after submaximal exercise vs. control sessions. No significant change occurred in HIV for SBP (-4.2 ± 18.9 mmHg; $P=0.5$), aortic pressure (-5.1 ± 13.0 mmHg; $P=0.2$), or SDNN ($+5.5 \pm 25.6$ ms; $P=0.4$). **CONCLUSION:** Healthy, but not HIV-infected men, exhibited acute blood pressure reduction after submaximal aerobic exercise. The higher central arterial stiffness and lower vagal modulation among HIV patients may help to explain the absence of PEH in this group. Supported by FAPERJ Grant.

Fibromyalgia Patients Display Blunted Cardiovascular Responses During Repeated Exercise Stress

Ethan V. Bandri¹, Courtney D. Jensen¹, Cynthia Villalobos¹, Staci R. Stevens², Jared Stevens², Todd E. Davenport¹, J Mark VanNess¹. ¹University of the Pacific, Stockton, CA. ²Workwell Foundation, Ripon, CA.

(No relevant relationships reported)

Fibromyalgia syndrome (FMS) affects nearly 10 million people in the United States and an estimated 6% of the world's population. FMS is idiopathic and characterized by severe pain (typically in joints and musculature), fatigue, and malaise. Pain and fatigue may limit physical activity, but other factors such as post-exertional malaise, may also contribute. **PURPOSE:** To examine exertional and post-exertional cardiovascular responses. **METHODS:** Thirty-five patients with fibromyalgia and 8 sedentary controls performed two cardiopulmonary exercise tests (CPET) to maximal exertion separated by 24 hours. Heart rate (HR) was measured continuously via ECG and blood pressure (BP) was recorded every two minutes. Independent samples T-tests compared differences between FMS patients and sedentary controls. Multiple linear regressions observed the effects of FMS on cardiovascular statistics (HR, SBP, Rate pressure product; RPP) at anaerobic threshold (AT) and VO_2 max (peak), controlling for confounding variables (age, sex, BMI, workload, and any additional medical conditions). **RESULTS:** Patients were 44.6 ± 9.8 years old, 27.5 ± 6.1 kg/m² BMI, and mostly female (88.4%). FMS and sedentary controls did not differ in age or BMI. FMS and sedentary controls did not differ in VO_2 ($p=0.62$), workload ($p=0.29$), SBP ($p=0.44$), DBP ($p=0.989$), RPP ($p=0.05$) during test 1. At AT, FMS did not influence HR ($\beta=-3.71$, $p=0.53$), SBP ($\beta=-3.94$, $p=0.67$), or RPP ($\beta=-1,478.37$, $p=0.35$) at test 1, but did at test 2 for HR ($\beta=-20.69$, $p=0.003$) and RPP ($\beta=-5,035.79$, $p=0.003$). When comparing test 1 to test 2 with the same variables, FMS influenced both HR ($\beta=-15.956$, $p=0.001$) and RPP ($\beta=-3,227.35$, $p=0.01$), but not SBP ($\beta=-3.60$, $p=0.686$). At peak, FMS influenced HR ($\beta=-23.80$, $p=0.012$) and RPP ($\beta=-5,078.36$, $p=0.040$) for test 1, but did not influence SBP ($\beta=-2.86$, $p=0.786$). This was also observed during test 2 for HR ($\beta=-23.30$, $p=0.004$), RPP ($\beta=-7,373.82$, $p=0.008$), and SBP ($\beta=-13.27$, $p=0.294$). When comparing test 1 to test 2 at peak, FMS did not influence HR ($\beta=-0.31$, $p=0.974$), or RPP ($\beta=-2,453.78$, $p=0.175$), but did influence SBP ($\beta=-14.72$, $p=0.029$). **CONCLUSION:** Post-exertional effects blunt the cardiovascular responses to exercise in FMS. This post-exertional effect has not been clearly elucidated in this illness and may help in understanding the illness.

A Nonadapted Cardiac Autonomic Regulation Following Repeated Bouts Of Eccentric Exercise

Choun-Sub Kim, Min-Ghyu Sun, Maeng-Kyu Kim. *Kyungpook National University, Daegu, Korea, Republic of.*

Email: blknight7@naver.com

(No relevant relationships reported)

Due to lower cardiovascular demand despite of high-force generation, eccentric contraction (EC) have recently been preferred in sports and clinical practice. However, EC exercise training may lead to cardiac autonomic imbalance. The effects of EC and repeated bouts of EC on cardiac autonomic regulation and adaptation along with exercise-induced muscle damage (EIMD) are unknown. **PURPOSE:** The present study was performed to examine changes in indices of heart rate variability (HRV) as well as the signs of EIMD after the maximal EC exercise and to determine whether the cardiac autonomic regulation would be adapted by the so-called "repeated bouts effect". **METHODS:** Repeated bouts of maximum voluntary EC of the knee extensors on isokinetic dynamometer were performed in twelve young men. To evaluate signs of EIMD, muscle strength, range of motion (ROM), muscle pain and swelling, creatine kinase activity, and echo intensity of rectus femoris were measured. HRV from RR intervals was analyzed to identify cardiac autonomic balance during 5-min. All parameters were measured before and post-EC (24, 48, 72, and 96 h). The second bout of EC was measured 3-week later using the same leg. **RESULTS:** There were significant changes in ROM, muscle pain and swelling, and echo intensity as EIMD markers following ECC exercise, respectively. After EC exercise, resting normalized low frequency (LF nu) and low to high frequency ratio (LF/HF ratio) of

HRV spectra were significantly increased compared to those at baseline, but these indices did not return to baseline level up to 96 h. Besides, there were no statistical differences between EC and repeated bouts of EC in LF nu and LF/HF ratio, respectively. **CONCLUSIONS:** From these results we suggested EC itself showed the sympathovagal imbalance of HRV index in men. Moreover, unlike the changes in conventional markers of EIMD following EC, the cardiac autonomic regulation was not adapted to the second bouts of EC, suggesting unique pattern of cardiac autonomic regulation following repeated bout of EC. Natural Counterpulsation Explains Cardiocomotor Synchronization In Distance Runners

Chi-An W. Emhoff¹, Paul D. Mannheim², Jeffery L. Bleich³, Robert F. Chapman, FACSM⁴. ¹Saint Mary's College of California, Moraga, CA. ²No Affiliation, Pleasanton, CA. ³Stanford University, Palo Alto, CA. ⁴Indiana University, Bloomington, IN. (Sponsor: Robert F. Chapman, FACSM)

Email: cwe1@stmarys-ca.edu

(No relevant relationships reported)

Cardiocomotor synchronization, when step rate and heart rate naturally occur with a 1:1 ratio, has been well-described in studies of running and walking. A proposed explanation for this phenomenon is that the frequency match enables cardiac counterpulsation via diastolic stepping, a potentially adaptive physiological behavior that may improve hemodynamic efficiency during ambulation. **PURPOSE:** Highly trained runners were studied to assess the prevalence of cardiocomotor synchronization and whether the step-to-heart phase timing preferentially occurred during diastole, facilitating natural counterpulsation. We hypothesized that unprompted heart rate and step rate entrainment would be present in our cohort of elite runners and the synchronization would occur during the diastolic phase of their cardiac cycles. **METHODS:** Eleven elite male endurance athletes completed three stages of over-ground running separated by ample recovery. The stages consisted of 12 min at 17.06 km/h (5:40 min/mi), 11 min at 18.67 km/h (5:10 min/mi), and 5 min at 21.08 km/h (4:35 min/mi), for a total running time of 28 minutes. A chest strap-based sensor transmitted and recorded real-time ECG and three-axis accelerometry data. Proprietary software was then used to analyze data for timing comparison of step rate, heart rate and the step-to-heart cycle phase relationship. **RESULTS:** When the frequencies of step and heart rates were matched, six of the eleven athletes displayed episodes of prolonged (>30 sec) diastolic stepping during at least one of the three speeds. Three runners exhibited prolonged diastolic stepping for $18 \pm 6\%$ of the first stage. All six runners exhibited prolonged diastolic stepping for $26 \pm 15\%$ of the second stage. Three runners exhibited prolonged diastolic stepping for $28 \pm 15\%$ of the third stage. Five of the eleven athletes did not experience any episode of cardiocomotor synchronization, due to heart rate being consistently lower than step rate. Only one episode of prolonged systolic stepping was observed. **CONCLUSIONS:** Unprompted cardiocomotor synchronization occurs with highly trained runners and is associated with diastolic stepping and natural counterpulsation, suggesting that the entrainment for hemodynamic advantages may be a driving force behind the coupling of heart rate and step rate.

Resistance Exercise And Caffeine On Performance, Hemodynamics, And Pulse Wave Reflection Measure In Resistance-trained Women

Kayla R. Hare, Therese Smith, Erica M. Marshall, Jason C. Parks, Stacie M. Humm, Meredith C. Paskert, Sarah G. Kearney, J Derek Kingsley, FACSM. *Kent State University, Kent, OH.*

(No relevant relationships reported)

PURPOSE: To investigate the effects of caffeine ingestion in conjunction with acute resistance exercise in resistance-trained women on resistance exercise performance, cardiovascular hemodynamics, and pulse wave reflection. **METHODS:** Eleven resistance-trained women (Mean Age \pm SD=24 \pm 4yrs) ingested either a placebo (PL) or caffeine (4mg/kg), separated by 72hrs, in a double-blind, crossover design. Heart rate (HR), mean arterial pressure (MAP), and pulse wave reflection measures were assessed at rest (Rest1), 45 minutes post-consumption (Rest2), immediately post-exercise (Post1), and 10 minutes post-exercise (Post2). Participants performed two sets of 10 repetitions at 75% 1-repetition maximum (1RM), and one set with repetitions to failure at 70% 1RM on the squat and bench press. Paired t-tests were used to analyze total volume the across conditions. Hemodynamics and pulse wave reflection were analyzed with repeated measures ANOVAs to determine the effects of condition (PL and caffeine) across time (Rest1, Rest2, Post1, Post2). **RESULTS:** There was no statistical differences for total volume on the squat ($p=0.9$) or bench press ($p=0.4$). There were no significant two-way interactions for any variable. There was no main effect of time for MAP ($p=0.09$). There were significant main effects of time for HR ($p=0.0001$), augmentation index (AIx, $p=0.001$), and for AIx normalized to 75bpm (AIx@75,

$p=0.0001$). HR increased significantly at Rec1 and Rec2 compared to Rest1 and Rest 2 (PL: Rest1: 61 ± 9 bpm, Rest2: 59 ± 10 bpm; Rec1: 87 ± 16 bpm, Rec2: 83 ± 14 bpm; Caffeine: Rest1: 58 ± 7 bpm, Rest2: 58 ± 10 bpm, Rec1: 86 ± 18 bpm, Rec2: 82 ± 15 bpm). This was also seen for AIx (PL: Rest1: $6.8\pm 8.5\%$, Rest2: $2.3\pm 11.6\%$, Rec1: $26.5\pm 9\%$, Rec2: $19.1\pm 9.1\%$; Caffeine: Rest1: $9.6\pm 10.2\%$, Rest2: $7.2\pm 10\%$, Rec1: $27.8\pm 16.2\%$, Rec2: $22.2\pm 12.2\%$) and AIx@75 (PL: Rest1: $1.7\pm 9.1\%$, Rest2: $-5.7\pm 14\%$, Rec1: $32.3\pm 10.8\%$, Rec2: $24.2\pm 12\%$; Caffeine: Rest1: $1.2\pm 11.5\%$, Rest2: $-0.8\pm 11.2\%$, Rec1: $28.9\pm 19.8\%$, Rec2: $23.6\pm 17\%$). **CONCLUSIONS:** These data suggest that the ingestion of 4mg/kg of caffeine provides no ergogenic effect in resistance-trained women. Additionally, caffeine consumption, in addition to performing resistance exercise, does not demonstrate alter hemodynamics or pulse wave reflection in resistance-trained women.

 Email: amanda.zaleski@hhchealth.org
 (No relevant relationships reported)

Aerobic exercise acutely reduces blood pressure (BP) 5-7 mmHg among adults with hypertension, termed *postexercise hypotension* (PEH). PEH has been shown to be highly correlated to the BP response to exercise training in the laboratory. However, this relationship has yet to be explored under ambulatory conditions and compared to a control sham session (CONTROL) which is necessary to account for the circadian variation in ambulatory BP (ABP). **PURPOSE:** To examine the relationship between PEH (ABP_{ACUTE}) and the systolic BP (ASBP) and diastolic ambulatory BP (ADBP) responses to aerobic exercise training (ABP_{CHRONIC}). **METHODS:** Adults with hypertension (n=24) completed a graded-exercise stress test (GEST) and CONTROL before and after 12wk moderate intensity aerobic exercise training. Ambulatory BP was assessed immediately after each experiment until the next morning and averaged at hourly intervals over 19hr. ABP_{ACUTE} was the difference between pre-training GEST minus CONTROL ABP. ABP_{CHRONIC} was post- minus pre-training CONTROL ABP. ANCOVA tested differences in ABP over time with resting BP as a covariate. Multiple variable regression examined relationships among ABP_{ACUTE} and ABP_{CHRONIC}. **RESULTS:** Subjects were middle-aged (52.3 ± 10.8 y), physically inactive adults with hypertension ($136.3\pm 10.7 / 85.2\pm 8.9$ mmHg). Following the GEST, ABP_{ACUTE} (ASBP/ADBP) were lower -5.9 ± 5.7 mmHg / -2.9 ± 4.1 mmHg than CONTROL (ps<0.006). Following 12wk of aerobic exercise training, post-training ABP CONTROL ($137.9\pm 11.0 / 81.7\pm 6.5$ mmHg) was not different than pre-training ABP CONTROL ($137.5\pm 6.6 / 80.5\pm 5.7$; ps>0.404). Multivariable regression analysis revealed that resting SBP, body mass index (BMI), and ASBP_{ACUTE} explained ~40% of the variance in ASBP_{CHRONIC}, with ASBP_{ACUTE} explaining ~17% of the variance in ASBP_{CHRONIC} (p=0.03). Similarly, resting DBP, BMI, and ADBP_{ACUTE} explained ~40% of the variance in ADBP_{CHRONIC}, while DBP_{ACUTE} explained ~11% of the variance to DBP_{CHRONIC} (p=0.06). **CONCLUSION:** ABP_{ACUTE} explained ~11-17% of the variability in exercise training-induced changes in ABP_{CHRONIC}. The magnitude of the correlations we observed between ABP_{ACUTE} and ABP_{CHRONIC} under ambulatory conditions appear to be less than those reported previously in the laboratory and merit further investigation.

Post-exercise Cardiac Autonomic Modulation: Comparison Between Triathlon And High-intensity Functional Training Athletes.

Gabriel Cartaxo Barbosa da Silva, Freddy Enrique Ramos Guimarães, Michelle Teles Morlin, Edgard MKVK Soares, Daniel Saint Martin, Guilherme Eckhardt Molina. *Universidade de Brasilia, Brasilia, Brazil.*
 Email: gabriel.cartaxo@hotmail.com
 (No relevant relationships reported)

PURPOSE: To verify if athletes submitted to volume overload display differences in the cardiac autonomic function throughout the post-exercise recovery phase comparatively to athletes submitted to resistance overload.

METHODS: 30 men were divided into three equal groups (p>0,05): non-athlete group (n=10 30.8±3.0 year, BMI: 24.6±2.7 kg/m²), high-intensity functional training athletes (n=10, 31.4±2.9 year, BMI: 31.4±2.2 kg/m²), and triathlon athletes (n=10, 31.2±2.8 year, BMI: 23.1±1.8 kg/m²). Participants underwent a maximal graded treadmill exercise test followed by a five-minute of active recovery protocol (2,4km/h 2,5%). During the post-exercise recovery phase, a valid R-R intervals series were recorded (5min) using a valid and reliable heart rate monitor. The data were processed off-line using the Kubios HRV - Heart Rate Variability Software. A Kruskal-Wallis test was used to determine differences in SD1 and SD2 indices between all groups. The SD1 and SD2 indices were used to assess the degree of parasympathetic reactivation and global cardiac modulation, respectively over the recovery phase. Heart rate variability, by means, SD1 and SD2 indexes of Poincaré Plot were recorded during the 30s; 1stmin; 3rdmin and 5thmin of recovery to evaluate the cardiac autonomic function (CAF).

RESULTS: No significant differences were found in parasympathetic and global cardiac modulation between groups, There were no difference between 3 groups in SD1-30s (2.66-3.15; p = 0.29), SD1-1st min (2.52-3.24; p = 0.23), SD1-3rd min (2.87-3.72; p = 0.58), SD1-5th min (3.08-4.29; p = 0.44), SD2-30s (2.22-2.88; p = 0.21), SD2-1st min (2.57-2.92; p = 0.39), SD2-3rd min (4.36-5.78; p = 0.58), SD2-5th min (5.34-6.79; p = 0.53). Possibly, the magnitude of differences is small, which warrants a larger sample size than used in our study to detect statistical differences.

CONCLUSIONS: In our study, no significant differences in parasympathetic and global cardiac modulation were found between groups. These initials results show that individuals submitted to resistance and volume overload training have similar abilities of the autonomic branches (sympathetic and parasympathetic) on the modulation of the heart throughout the post-exercise recovery.

 (No relevant relationships reported)

PURPOSE: Ultra-endurance running, classified as any distance greater than a marathon (42.2km), is strenuous on the body. These extreme distances may include difficult weather conditions or terrain (e.g., heat, cold, altitude, trails, etc.) and could lead to changes in urine biomarkers resulting from damage to essential organs (e.g., kidney, liver, and heart). The purpose of this study was to determine the effects of running a grueling 161.3km trail race on general characteristics, presence of blood, and other molecules in the urine of an elite ultra-endurance runner (EUR). **METHODS:** Urine specimens were collected from a 32y male EUR (170cm, 64.5kg, age-ranked 98.7%[ultrasignup.com]), before and after completing the Western States Endurance Run (WSER). Samples were analyzed using 11-parameter urinalysis strips (Med Lab Diagnostics, Laguna Beach, CA) one day pre-race and ~2h post-race. **RESULTS:** EUR finished the WSER in less than 16 hours. Main findings showed red blood cell (RBC) count increased from 0 to ≥ 200 cells/ μ l (indicated hemolysis), bilirubin increased from 0 to 17 mmol/L (biprodut of hemoglobin), and urobilinogen increased from 0 to 3.2 mmol/L (indicated RBC destruction) post-race. Urine proteins and ketone abundance increased while ascorbate decreased post-race. **CONCLUSIONS:** Elevated urinary levels of red blood cell derivatives post-WSER highlight the formidable hematologic implications of ultramarathon running. Modalities to mitigate this phenomenon as well as an improved understanding of the systemic consequences of and time to recover from this exercise-induced hemolysis are of interest.

 (No relevant relationships reported)

Exercise training has been demonstrated to cause beneficial cardiac adaptations in different patient groups. However, comparative studies on different exercise training modes are sparse in sedentary women diagnosed with arterial hypertension. **PURPOSE:** To examine effects of 15 weeks of soccer training versus low volume high intensity interval swim training and prolonged continuous moderate intensity swim training on cardiac structure and function in middle-aged, sedentary, hypertensive women. **METHODS:** Sedentary, premenopausal women with mild-moderate arterial hypertension ($n = 73$) with average (\pm SD) age, height, weight and body fat of 45 ± 6 yrs, 165 ± 6 cm, 80.0 ± 14.1 kg and $42.6 \pm 5.7\%$ were randomized into a soccer training (SOC; $n=19$), moderate intensity swimming (MOS; $n=18$), high intensity interval swimming (HIS; $n=17$) and control (CON; $n=19$) groups. SOC completed a total of 45 ± 3 training sessions over the 15-week intervention period. SOC completed 1-h sessions consisting of small-sided soccer games (4v4 to 6v6). MOS completed 1 h sessions of continuous front-crawl swimming, with the participants encouraged to swim as far as possible during each session, while HIS performed 6-10x30-s all-out front-crawl swimming intervals interspersed with 2 min of passive recovery; thus, 3-5 min of effective swimming time. Cardiac measures were evaluated by echocardiography. **RESULTS:** Left ventricular mass increased ($p<0.05$) by 11.5 ± 14.1 and 8.7 ± 16.5 g in SOC and HIS with no change in MOS and CON. Left ventricular diastolic properties (as the ratio of early to late mitral inflow velocities, E/A ratio) improved ($p<0.05$) by 38.5 ± 46.9 , 24.6 ± 25.4 and $26.6 \pm 48.2\%$ in SOC, MOS and HIS, respectively, with no change in CON. Right ventricular function determined by tricuspid annular plane systolic excursion was improved by $8.9 \pm 13.7\%$ in SOC only. When data from the three training groups were pooled together left ventricular mass rose by $8.0 \pm 11.3\%$, with greater change-scores compared to CON ($2.2 \pm 11.0\%$). **CONCLUSION:** Exercise training improves cardiac structure and diastolic function in hypertensive women with superior effects of a hybrid training mode like soccer compared both to endurance training and high intensity interval training alone.

2619 Board #80 May 29 10:30 AM - 12:00 PM

Extended Cardiac Rehabilitation Does Not Improve Exercise Adherence More Than Usual Care

Inger-Lise Aamot Aksetoy, Elisabeth Kleivhaug Vesterbekkmo, Knut Asbjørn Rise Langlo, Håvard Dalen, Asbjørn Støylen.
 Norwegian University of Science and Technology, Trondheim, Norway.
 Email: Inger-Lise.Aksetoy@ntnu.no
 (No relevant relationships reported)

PURPOSE: Exercise adherence is in general poor after cardiac rehabilitation (CR). In Norway, standard exercise-based CR typically offers 12 weeks of hospital-based supervised exercise at moderate or high intensity. The use of high-intensity interval training (HIT) in CR expands; however, it is still unclear how HIT affects exercise adherence. The purpose of this study was to assess the effect of an extended community-based or home-based CR program on long-term exercise adherence. **METHODS:** Between August 2014 and June 2017, 161 persons (27 women, age 62.3 (8.7)/134 men, age 60.1 (8.9)) were recruited. All had completed a HIT-based CR at St. Olav's Hospital in Trondheim, Norway. They were randomized in a 1:1:1 ratio to an extended supervised community-based CR (ExCR), a home-based CR (HCR) or a control group (CG). The extended CRs (ExCR and HCR) consisted of one HIT session and two additional sessions a week for eight weeks. The ExCR got a follow-up session every third month until one year after inclusion. The CG received usual care (standard advice for exercise and life style). Measurements were performed at baseline (T1), at 1 year (T2) and 2 years (T3) after inclusion. Primary outcome was peak oxygen uptake (VO2peak) at 2 years. Secondary outcome was achievement of current guidelines in regard of physical activity (PA) at moderate (MPA) and vigorous (VPA) intensity, measured with accelerometer. Data are analyzed with mixed linear model.

RESULTS: Out of 161 participants, 144 (89%) completed the 2 year follow-up. VO2peak (ml/kg/min) was not significantly different between groups ($p=0.777$) at T1 (33.1 (7.7), 33.6 (8.5), 34.0 (7.2)), T2 (33.1 (7.9), 33.1 (8.4), 33.9 (7.4)) or T3 (30.9 (7.5), 32.2 (8.6) and 32.0 (7.3) for ExCR, HCR and CG, respectively). The decrease in VO2peak over time was significant from T2 to T3 ($p=0.024$). Daily average of minutes in MPA and VPA were not significantly different between groups ($p=0.441$ and $p=0.557$ respectively) at any time. There was a significant reduction from T1 to T2 in both MPA (107 (61) min to 100 (59) min, $p=0.043$) and VPA (14 (19) min to 11 (18) min, $p=0.007$).

CONCLUSIONS: Extended cardiac rehabilitation did not enhance exercise adherence compared to usual care after a HIT-based CR program. Despite a decrease in VO2peak over two years, the amount of physical activity met the current guidelines.

POSTURAL ORTHOSTATIC TACHYCARDIA SYNDROME (POTS) AND CARDIAC REHABILITATION: CLINICAL SUCCESSES AND CHALLENGES.

Mireille Landry, Paula Harvey, Tosin Osuntokun, Deborah Childerhose, Faith Delos-Reyes, Miriam Fong, Jennifer Price.
 Women's College Hospital, Toronto, ON, Canada.
 Email: mireille.landry@wchospital.ca
 (No relevant relationships reported)

Postural Orthostatic Tachycardia Syndrome (POTS) is a chronic debilitating form of dysautonomia most prevalent in premenopausal women. POTS continues to be poorly understood, however evidence suggests exercise and lifestyle interventions may ameliorate symptoms such as fatigue pre-syncope, and exercise intolerance and may in some patients induce remission. A recent position statement on POTS recommends exercise and lifestyle modification as a first line non-pharmacological strategy and cardiac rehabilitation (CR) is increasingly prescribed for this purpose. **PURPOSE:** To describe the experience of a gender-specialized CR program for patients with POTS. **METHODS:** A retrospective case review was undertaken to describe the demographics and outcomes of women living with POTS who attended CR from 2016-2019. **RESULTS:** Baseline characteristics showed 42 women aged 18-62 years (mean \pm SD, 35 ± 13.02), 62% unemployed and 68% exhibiting below average age-predicted fitness in Metabolic Equivalents (METS ml/min/kg, 9.7 ± 10.42) and poor function on the Duke Activity Status Index (9.7 ± 10.4). Quality of life as measured by the Short Form 36 physical component score (27.7 ± 6.6) were significantly lower than expected while the mental component score was average (45.0 ± 7.7). 50% of participants had mild depression while 31% had moderate to severe depression on the Beck Depression Inventory (15.9 ± 9.0). Of those, 62% ($n=26$) of participants attended onsite CR, 33% ($n=14$) of patients opted for an exercise consult or a home program. Despite personalized programs with recumbent aerobic exercise, lifestyle education, young women's peer support, dietitian and pharmacy counseling, completing CR was challenging. Adherence rates to the weekly onsite CR sessions were low due to ongoing symptoms of postural intolerance, however, only a small number who elected to participate did not complete the CR program ($n=2$). **CONCLUSIONS:** Patients with POTS have impaired quality of life with low fitness, high levels of unemployment and depression. There is early evidence that a traditional CR model may be more of a challenge in women with POTS and a needs assessment is warranted. Additional components of CR such as peer support, stress management, and self-care strategies may be important to enhance the therapeutic efficacy of this intervention.

 (No relevant relationships reported)

Postural Orthostatic Tachycardia Syndrome (POTS) is a form of dysautonomia and a clinical syndrome of orthostatic intolerance. This chronic debilitating condition most prevalent in premenopausal women is characterized by both cardiac and non-cardiac symptoms, including exercise intolerance. Patients may benefit from a multidisciplinary approach to assist with non-pharmacological management, such as lifestyle modification and exercise, the only intervention currently shown to induce clinical remission. A cardiac rehabilitation (CR) program has supported these patients as part of their current model of care. A traditional CR setting has been challenging and there is a need to develop novel and effective ways to support these patients. **PURPOSE:** To describe the creation of a self-management intervention tailored to the needs of women living with POTS. **METHODS:** Retrospective chart reviews, literature review, patient surveys and staff feedback were completed and integrated with evidence-based guidelines to inform the creation of a program focusing on best practice and patient needs. **RESULTS:**

Between 2016-2019, 42 women aged 18-62 years (mean=35 ± 13.02) were referred to CR with 68% exhibiting below average age-predicted fitness in Metabolic Equivalents (METS ml/min/kg, (9.7 ± 10.42). 62% of participants attended onsite CR while 33% of patients opted for a home program. A multidisciplinary team developed content and selected outcome measures better suited to evaluate this population. Based on the literature, recumbent aerobic exercise, resistance training and counter pressure maneuvers are important components to physical activity participation. Strategies to manage postural intolerance such as pacing, hydration, salt intake and compression garments are included to promote first line non-pharmacological approaches to POTS management. Based on feedback from past participants in the traditional CR model, peer-support and stress/anxiety management are highly valued and therapeutic. **CONCLUSIONS:** The self-management and peer support model for POTS was developed with up-to-date recommendations and non-pharmacologic interventions. Effectiveness and feasibility of this new model of care will be evaluated. Future developments in virtual care will be explored to enhance access to the program.

Achievement Of Current Guideline Levels Regarding Cardiovascular Risk Factors After Cardiac Rehabilitation

Pernille Hagen, Elisabeth Kleivhaug Vesterbekkmo, Inger-Lise Aamot. *Norwegian University of Science and Technology, Trondheim, Norway.*
(No relevant relationships reported)

Studies conducted both in Norway and Europe have found low achievement of current guidelines regarding cardiovascular risk factors. Physical activity (PA) positively affects several risk factors of coronary heart disease (CHD). Extended cardiac rehabilitation (CR) increases maintenance of PA-level. **PURPOSE:** To explore whether extended CR had an additional effect on the lipid profile in patients with CHD, and further to investigate the achievement of current guidelines in regards of PA. **METHODS:** A randomised controlled study. Participants (112 men/22 women) who had completed standard CR were randomly assigned to either extended CR run by municipality (MBG), home-based extended CR (HBG) or a control group (CG). The extended CR groups (MBG and HBG) completed 1 session of interval training (4 times 4 minutes) for 8 weeks and were encouraged to two optional additional exercises per week. After 8 weeks the MBG got a follow-up session every third month until 1 year after inclusion. The CG received standard lifestyle advice at baseline and had no follow-up throughout the year. **RESULTS:** Results are presented in Table I. At 1-year follow up 50% of all participants and 56% of participants on high-intensive statin therapy (HIST) achieved low-density lipoprotein cholesterol levels below 1.8 mmol/L. 73 (88%) participants were found adherent to their lipid lowering therapy. The majority of participants (97% and 91.5%) met the recommended target for both triglycerides and weekly level of moderate PA, respectively. **CONCLUSIONS:** Our findings suggest that current lipid lowering therapy in patients with CHD is inadequate. We suggest that a larger proportion of patients should be using HIST, Ezetimibe combined with statins or PCSK9 inhibitors. Further, extended CR was not found to have any additional effect on the lipid profile. The majority of participants reached recommended PA-levels at both baseline and 1-year, suggesting that extended CR does not lead to higher PA-levels.

Table I. Outcome measures of lipids, HbA1c and body mass index at baseline and 1-year follow-up according to intervention groups.

Skeletal Muscle Adaptation In Cardiac Rehabilitation Patients Undertaking Traditional Or Higher Intensity Stair-climbing Exercise

Changhyun Lim¹, Emily C. Dunford¹, Sydney E. Valentino¹, Sara Y. Oikawa¹, Chris McGlory², Maureen J. MacDonald¹, Stuart M. Phillips, FACSM¹. *McMaster University, Hamilton, ON, Canada.* ²Queen's University, Hamilton, ON, Canada.
Email: limc16@mcmaster.ca
(No relevant relationships reported)

Exercise-based cardiac rehabilitation is associated with reduced secondary events in coronary artery disease (CAD) patients. Despite this evidence, the rate of participation

in cardiac rehabilitation exercise is low. There is a lack of information evaluating how both traditional and time-reduced higher intensity protocols affect muscle metabolism in this population, even though CAD exacerbates skeletal muscle defects that contribute to the poor metabolic phenotype.

PURPOSE: To determine the effect of a traditional cardiac rehabilitation exercise program and an alternative stair climbing-based high-intensity interval training program on the skeletal muscle phenotype in CAD patients. **METHODS:** 16 participants (15M, 1F) were randomly assigned to either traditional moderate-intensity exercise (7M, TRAD) or brief but higher-intensity interval stair climbing exercise (8M, 1F, STAIR). Both programs were 12 weeks (3d/w) in duration, each TRAD exercise session consisted of 45 minutes of moderate-intensity aerobic exercise, and each STAIR session consisted of 3 bouts x 6 flights of high-intensity stair climbing. Muscle biopsies were collected from the *vastus lateralis* at baseline and after 12 weeks of training. Immunofluorescent staining of muscle cross sections was completed to determine fiber size, capillarization, satellite cell (SC) and myonuclear content. **RESULTS:** There were no differences in the cross-sectional area and myonuclear domain of type I or II fibers following 12 weeks of either TRAD or STAIR training (p>0.05). Following 12 weeks, both exercise programs resulted in increases in, myonuclear content (type I: TRAD Δ0.4±0.5, STAIR Δ0.3±0.6, p=0.012; type II: TRAD Δ0.8±0.7, STAIR Δ0.4±0.7, p=0.006), capillary contacts (type I: TRAD Δ0.5±0.5, STAIR Δ0.2±0.7, p=0.038; type II: TRAD Δ1.2±0.6, STAIR Δ0.7±0.4, p<0.001), capillary-to-fiber perimeter exchange index (type I: TRAD Δ1.6±1.8, STAIR Δ0.4±0.8, p=0.01; type II: TRAD Δ1.8±1.7, STAIR Δ0.7±0.8, p=0.002), and capillary to fiber ratio (type II: TRAD Δ0.5±0.3, STAIR: Δ0.3±0.2, p<0.001). **CONCLUSION:** Both brief stair climbing-based high-intensity interval training and traditional cardiac rehabilitation exercise result in improvements in variables associated with skeletal muscle health in CAD patients.

(No relevant relationships reported)

PURPOSE: To determine the effects of 36 exercise-based cardiac rehabilitation (CR) sessions on walking speed, performance times and hemodynamic variables in cardiac patients. A second aim was to determine the reliability of the timed-up-and-go (TUG) test in CR patients. **METHODS:** Forty-seven patients (age = 58.2 ± 11.6 yr., height = 168.6 ± 8.0 cm, weight = 80.3 ± 12.8 kg, BMI = 28.3 ± 4.5 kg/m²) were measured on heart rate (HR), systolic (SBP) and diastolic (DBP) blood pressure, 6-min walking test (6MWT), and TUG at baseline (B), and following T4 (T24) and T6 (T36) CR sessions. The TUG was performed twice interspersed with a 2-min seated rest. One-way repeated measures ANOVA and Fisher's LSD post hoc test identified significant mean differences. The intraclass correlation coefficient (ICC) and 95% confidence intervals (95%CI) were used to determine the reliability of TUG at B, T24, and T36. Relative change (Δ%) from B to T24 and T36 and from T24 to T36 were computed for TUG and 6MWT. **RESULTS:** 6MWT distance improved from B (466.4 ± 72.8 m) to T24 (538.3 ± 67.2 m, p ≤ 0.001), and T36 (554.5 ± 69.1 m, p ≤ 0.001), and from T24 to T36 (p = 0.012). 6MWT walking speed improved from B (4.7 ± 0.7 km/h) to T24 (5.4 ± 0.7 km/h, p ≤ 0.001), and T36 (5.6 ± 0.7 km/h, p ≤ 0.001), and from T24 to T36 (p = 0.012). Exertional HR improved from B (100.1 ± 16.7 bpm) to T24 (106.7 ± 20.4 bpm, p ≤ 0.011), and T36 (108.2 ± 18.6 bpm, p = 0.003). Exertional SBP improved from B to T36 (123.6 ± 20.6 vs. 130.8 ± 19.5 mmHg, p = 0.006). TUG performance times improved from B (5.5 ± 1.2 s) to T24 (5.1 ± 0.9 s, p = 0.003), and T36 sessions (4.9 ± 0.7 s, p ≤ 0.001), and from T24 to T36 (p = 0.015, η² = 25.6). TUG performance speed improved from B (4.1 ± 0.8 km/h) to T24 (4.4 ± 0.7 km/h, p = 0.011), and T36 (4.5 ± 0.6 km/h, p ≤ 0.001), and from T24 to T36 (p = 0.033). Significant reliability coefficients were observed on the TUG (trial 1 vs. trial 2) on time at B (r = 0.91, p ≤ 0.001, 95%CI = 0.83 to 0.95), T24 (r = 0.94, p ≤ 0.001, 95%CI = 0.90 to 0.97) and T36 (r = 0.88, p ≤ 0.001, 95%CI = 0.79 to 0.94). The biggest Δ% in 6MWT occurred from B to T36 (Δ = 20.2 ± 13.4%, p ≤ 0.001), followed by B to T24 (16.8 ± 13.7%, p = 0.015), and from T24 to T36 (3.3 ± 7.9%, p ≤ 0.001). **CONCLUSION:** CR patients improved walking speed, TUG performance, exertional HR and SBP following 36 exercise-based CR sessions. A learning effect was observed on the second trial of the TUG.

Cardiac Rehabilitation Combined Training Improves Lower Limb Strength After 12 Sessions In Elderly Patients

Lady J. García¹, Fausto Y. Rojas¹, Germán D. Ochoa², Oscar H. Ortiz¹, Andrea Ramírez², John Duperly³. ¹Fundación Santa Fe de Bogotá, Bogotá, Colombia. ²Universidad de los Andes, Bogotá, Colombia. ³Universidad de los Andes and Fundación Santa Fe de Bogotá, Bogotá, Colombia.

Email: ladygaco@gmail.com

(No relevant relationships reported)

Increased quadriceps muscle strength has shown to decrease the risk of cardiovascular mortality by 34% in patients with coronary heart disease. Muscle mass and strength declines progressively in the elderly and training effects have been generally reported after 12 weeks. Adherence to cardiac rehabilitation programs is usually low, with less than 50% of patients completing 36 sessions in 12 weeks. There is still no consistent evidence that muscle strength in elderly patients can be improved after just 12 sessions of cardiac rehabilitation. **PURPOSE:** To evaluate the effect of 12 sessions of combined training on lower limb strength, in elderly patients attending a cardiac rehabilitation program 2-3 times per week. **METHODS:** Patients included eighty-four elderly (>60 yrs) (21 women, age 67 ± 6 yrs; 63 male, age 70 ± 7 yrs) attending a cardiac rehabilitation program in a university hospital in Bogotá city, Colombia. They were evaluated from January to September 2019 before and after 12 training sessions 2-3 times per week, which included 30 minutes of cardiovascular aerobic and 15 minutes of multifunctional strength training. Aerobic training was performed at 60 - 85% of the estimated maximal heart rate. Progressive resistance strength training included 3 sets of 10-15 repetitions of major muscle groups with 50 - 70% estimated 1-repetition maximum (1-RM) including elastic bands, cuff weights, free weights and gym machines.

Baseline and follow up evaluation at the 12th session were performed by a horizontal leg press machine with 1-RM estimation according to Brzycki formula: (1-RM: 100* load repetition / (102.78 - 2.78 *rep). Pre/post training changes were assessed by paired t tests.

RESULTS: After 12 training sessions a significant maximum strength increase was found, both for men (189.6 ± 42.6 vs 203.0 ± 47.4; p = 0.000), and women (116.1 ± 18.8 vs 140.6 ± 31.0; p = 0.000).

CONCLUSIONS: This study showed that twelve sessions of combined training in elderly patients attending a cardiac rehabilitation program, improved lower limb strength in less time than usually reported. This finding supports the importance and feasibility of including strength in addition to aerobic training to reduce cardiovascular risk in this growing population.

Chronotropic Index And Heart Rate Recovery After Exercise In Adolescents With Down Syndrome

Geiziane Leite Rodrigues Melo, Dahan Cunha Nascimento, Weldson Ferreira Abreu, Samuel Cunha Oliveira, Ronaldo Benford, Rodrigo Neves Neves, Thiago Santos Rosa, Milton Rocha Moraes. *Universidade Católica de Brasília, Águas Claras, Brazil.*

(No relevant relationships reported)

Individuals with Down syndrome (DS) have a reduced heart rate (HR) response to exercise which is the main contributor to low cardiorespiratory fitness in this population. A previous study has shown delayed heart rate recovery (HRR) in adults with DS performing exercise testing, however there is still a gap regarding the HRR response and chronotropic index in adolescents with DS. **PURPOSE:** To evaluate heart rate response treadmill exercise test and its impact on exercise in adolescents with DS compared to non-DS. **METHODS:** Eleven adolescents with DS (7 girls, 4 boys; age 14.1 ± 1.04 years) and 10 non-DS (6 girls, 4 boys; age 13.7 ± 1.2 years) performed peak treadmill test with heart rate measurements. HRR was defined as the reduction in heart rate from the rate at peak exercise to the rate at 1 and 2 minutes after the cessation of exercise. Chronotropic index was calculated by a formula [(peak HR - resting HR) / (220 - age - resting HR)] * 100. For comparisons between groups, the independent t test was used. **RESULTS:** Compared to control group, adolescents with DS presented lower peak HR, loading time (s) and distance (m) (p < 0.05). In contrast, adolescents with DS had resting HR values similar to those non-DS. Participants with DS showed slower HRR than non-DS at 1 minute (DS: 21.1 ± 6.95 beats / min; controls: 47.1 ± 6.99 beats / min) and 2 minutes (DS: 28.5 ± 7.38 beats / min; controls:

49.4 ± 6.39 beats / min) of recovery (p < 0.05). In addition, adolescents with DS have a lower CI (0.84 ± 0.09 vs 0.66 ± 0.09, p = 0.0001) when compared to their peers.

CONCLUSION: Adolescents with DS had attenuated post-exercise HRR that may be related to lower chronotropic response at peak intensities.

Influence Of Traumatic Lower-limb Amputation Severity On Biomarkers Of Cardiometabolic Health In British Military Personnel

James Lee John Bilzon. *University of Bath, Bath, United Kingdom.* (Sponsor: Professor James Betts, FACSM)

Email: j.bilzon@bath.ac.uk

(No relevant relationships reported)

Severe injuries sustained during military combat result in exceptional long-term healthcare and rehabilitation needs. It is unclear if previously physically active military personnel with lower-limb amputation(s) (LLA) have compromised cardiometabolic health following prolonged rehabilitation.

PURPOSE: To determine within and between group differences in biomarkers of cardiometabolic health in UK military personnel with unilateral (UNI) and bilateral (BI) LLA, nearing the end of their rehabilitation care pathway, compared to non-injured controls (CON).

METHODS: Sixteen UK military personnel with traumatic LLA (8 UNI, mean age 30±5yrs and 8 BI, mean age 29±3yrs) attended two 4-week inpatient rehabilitation admissions, separated by two 6-week home-based periods. Thirteen active age-matched males (28±5 yrs) acted as CON. Fasted blood samples (lipid profile) were taken prior to determining the insulin and glucose response to a 75g oral glucose load at baseline and 20 weeks. Data were analysed using 2-way mixed model ANOVA (group x time).

RESULTS: No significant interaction effects were observed for any biomarkers (Table 1). Biomarkers of cardiovascular and metabolic health were comparable between UNI LLA and CON (p>0.05). BI LLA demonstrated significantly elevated cardiovascular health risk (Total:HDL cholesterol ratio, p<0.001; triglyceride, p=0.001; and CRP, p=0.002), insulin resistance (HOMA2-β (p=0.030), and reduced insulin sensitivity (p=0.005) compared to CON.

CONCLUSIONS: Cardiometabolic health risk is comparable between UNI LLA and CON, but elevated in BI LLA. Further strategies to improve and support the long-term management of cardiometabolic health risk in BI LLA are warranted.

Abstract

Individuals with Down syndrome (DS) have lower peak oxygen uptake (VO_{2peak}) in comparison to individuals without DS. This is partly explained by autonomic dysfunction with lower peak heart rates observed during maximal exercise in DS compared to controls. Oxygen (O_2) pulse is the measure of oxygen uptake per heartbeat and is a product of stroke volume and arterial-venous difference. As such, it is widely used as an indicator of deconditioning and could provide unique information about exercise intolerance in individuals with DS. **Purpose:** To compare O_2 pulse between individuals with DS and a sex- and age-matched control group. **Methods:** Individuals with DS (n=17; male n=11; age (mean± standard deviation) = 25 ± 4 years) and controls (n=17; male, n=11; age 24 ± 3 years) completed a maximal exercise treadmill test with a previously validated protocol. Heart rate and oxygen uptake were averaged over 15-second intervals. O_2 pulse was calculated by dividing peak oxygen uptake by peak heart rate. Group differences were analyzed with independent t-tests. **Results:** Individuals with DS had lower height, absolute VO_{2peak} (p<.001), relative VO_{2peak} (p<0.001), peak heart rate (p<0.001), and O_2 pulse (p= 0.017) compared to controls. **Conclusion:** Individuals with DS demonstrated lower O_2 pulse in comparison to individuals without DS, potentially explained by deconditioning or population-specific physiologic limitations.

This research is partly supported by NIH K99R01 HD092606-01.

The Association Of Ground Reaction Forces With The Five Most Common Running Injuries

Caleb D. Johnson, Adam S. Tenforde, Jereme Outerleys, Irene S. Davis, FACSM. *Harvard Medical School, Cambridge, MA.*
(Sponsor: Irene Davis, FACSM)
(No relevant relationships reported)

Inconsistent associations have been reported for ground reaction force (GRF) variables and running injuries when grouping all injuries together. However, previous work has shown more consistent associations when focusing on specific injuries. **PURPOSE:** To establish general and injury-specific associations between GRFs and five common running injuries. **METHODS:** 126 runners presenting with patellofemoral pain (PFP), tibial bone stress injury (TBSI), plantar fasciitis (PF), Achilles tendinitis, or iliotibial band syndrome and 70 healthy controls (CON) completed an instrumented treadmill assessment at a self-selected speed. All were rearfoot strikers. Injured/control groups were matched for gender and running speed. Vertical average and instantaneous load rates (VALR, VILR) were calculated over the first 15% of stance. Peak vertical, posterior, medial (mGRF), and lateral forces were calculated over all of stance. Mean comparisons were made between the general injury (INJ) and CON groups, and specific injuries and CON. Further, optimal cutoff values were established for variables using ROC curves. Area under the curve (AUC) and odds ratios (ORs) were used to evaluate their diagnostic value. **RESULTS:** Mean differences for variables between CON and injury groups are presented below. Only VALR, VILR and mGRF showed significant differences between groups (p<0.05). Cutoffs for VALR had superior diagnostic value for PFP and PF (OR=5.8-10.6, AUC=0.70-0.73) compared to INJ (OR=3.8, AUC=0.65). This trend held for VILR (PFP: OR=5.1, AUC=0.72; INJ: OR=3.5, AUC=0.64) and mGRF (TBSI: OR=8.8, AUC=0.74; INJ: OR=3.0, AUC=0.60). **CONCLUSION:** VALR, VILR and mGRF variables showed significant associations with running injury, even when grouped across injuries. However, associations were driven by PFP, PF and TBSI. Diagnostic value of variables was greatly improved when separating specific from general injuries.

Sex-specific Knee Biomechanics Associated With Patellofemoral Pain In Amateur Runners During Running

Chen Yang¹, Bing Yu², Hui Liu³, Feng Qu³. ¹Nanjing Sport Institute, Nanjing, China. ²The University of North Carolina at Chapel Hill, Chapel Hill, NC. ³Beijing Sport University, Beijing, China.
Email: obayoung@foxmail.com
(No relevant relationships reported)

Patellofemoral Pain (PFP) is a common injury among runners. The mechanisms of sex differences associated with lower extremity biomechanics in PFP are still unclear.

PURPOSE: To determine the differences in knee biomechanics between male and female amateur runners with PFP and without PFP in running task. Further, to determine the sex-specific biomechanical factors associated with the development of PFP.

METHODS: 15 male and 10 female amateur runners aged 18 to 40 years with PFP were screened and enrolled in PFP group, 25 healthy amateur runners matched with the PFP group in sex, age, and running experience were recruited as control group. PFP group was tested running with and without knee pain (PFP with pain and PFP without pain groups), while control group performed one running test (running speed = 4.0 ± 0.3 m/s). Knee pain in PFP group was eliminated by decreasing the volume of running. Knee kinematics and kinetics during landing phase of running were reduced from reflective marker coordinates and ground reaction force data, as well as compared among groups and between sexes.

RESULTS: Peak knee valgus angle of running in PFP group with pain (male: 3.2 ± 4.2°, female: 4.8 ± 4.9°, P = 0.001) and control group (male: 1.9 ± 2.7°, female: 3.8 ± 3.0°, P = 0.001) were significantly lower compared to PFP group without pain (male: 4.5 ± 4.3°, female: 7.9 ± 3.1°). Peak knee external rotation moment of running in PFP group with pain (male: 0.021 ± 0.008 BW × BH, female: 0.019 ± 0.006 BW × BH, P = 0.019) and control group (male: 0.020 ± 0.006 BW × BH, female: 0.017 ± 0.006 BW × BH, P = 0.001) were significantly lower compared to PFP group without pain (male: 0.024 ± 0.009 BW × BH, female: 0.022 ± 0.008 BW × BH). Peak knee flexion angle of running in PFP group without pain (48.8 ± 5.6°) was significantly greater compared to control group for male participants (46.0 ± 3.6°, P = 0.008).

CONCLUSIONS: Decreased knee valgus angle and external rotation moment in running appeared to be compensations to avoid pain when amateur runners with PFP were running with pain, and increased knee valgus angle and external rotation moment might be biomechanical factors associated with the development of PFP. Increased knee flexion angle in running may be another critical biomechanical factor associated with the development of PFP for male amateur runners.

Assessing Between-limb Differences In Prospectively Injured And Uninjured Runners Using Dynamical Measures Of Gait

Gauri A. Desai, Allison H. Gruber. *Indiana University, Bloomington, IN.* (Sponsor: Joseph Hamill, FACSM)
Email: gaudesai@iu.edu
(No relevant relationships reported)

Between limb differences in the dynamic interactions of leg joints and segments may reflect rotational stresses and soft tissue strain experienced during gait, leading

to greater insight of running related injury mechanisms than discrete measures. **PURPOSE.** Determine between limb differences in coordinative variability (CAV) in prospectively injured and uninjured runners. **METHODS.** Over ground running (4.0 m/s ± 5%) was recorded with motion capture at enrollment. An injury was any running related pain that caused modified training for ≥1 day. Coupling angles between sagittal knee, transverse shank and frontal ankle angles were calculated via vector coding. Mean CAV was calculated for each couple within each third of stance (initial, mid, late). Asymmetry was quantified as the percent difference in CAV between legs. Wilcoxon Signed Rank Tests were used to compare CAV between legs within each group and between-group differences in CAV asymmetry were assessed with Mann-Whitney U Tests. **RESULTS.** Injured (n=16) runners had significantly greater shank-ankle and knee-shank CAV in the injured leg in initial and late stance but lower shank-ankle CAV in mid stance (P<0.05; Fig. 1). Uninjured (n=15) runners had significantly greater shank-ankle CAV in the right leg in initial and mid stance but in the left leg in late stance, and greater knee-shank CAV in the right leg in mid-stance (P<0.05). CAV asymmetry was similar between groups. **CONCLUSION.** We recommend comparing injured legs of injured runners to the matched leg of uninjured runners, rather than randomly selecting legs from the uninjured group. Greater knee-shank CAV in initial and late stance may influence prospective injury risk. **Fig 1.** Group mean CAV across stance for the injured and uninjured legs in the injured runners (top row) and between right and left legs in the uninjured runners (bottom row). Vertical dashed lines demarcate initial, mid and late stance. *p<0.05 indicates significant differences in CAV between legs.

Dynamic Stability In Runners With Plantar Fasciitis
 Devin K. Kelly¹, Kristyne Wiegand², Julia Freedman Silvernail¹.
¹UNLV, Las Vegas, NV. ²Whittier College, Whittier, CA. (Sponsor: John Mercer, FACSM)
 (No relevant relationships reported)

Plantar fasciitis (PF) is a common running injury associated with low arch height, and excessive loading and pronation. Research has shown gait alterations in individuals with PF including increased rearfoot eversion, forefoot plantarflexion, and MTPJ dorsiflexion, and reduced center of pressure (COP) duration at the heel. Changes in kinematics and COP trajectory may affect dynamic stability. Therefore, dynamic stability as measured by time to contact (TtC) may be reduced in runners with PF. **PURPOSE:** To determine differences in dynamic stability during the stance phase of running in individuals with PF. **METHODS:** Twenty runners were separated into two groups based on injury status (1: PF; 2: healthy). Kinematic and kinetic data were collected at 200 and 1000 Hz, respectively, as participants ran at 3.5 m/s ±5%. TtC of the COP to the medial and anterior boundaries of the base of support were calculated over the stance phase. Minimum TtC values were determined for each portion of stance per trial, averaged across five trials per participant and across participants per group. Differences in TtC between groups during early, middle, and late stance were determined using one-way ANOVAs with alpha level set at 0.05. **RESULTS:** Group demographics were similar. TtC was similar between groups during early and late stance and different during mid-stance (Table 1). **CONCLUSION:** TtC was similar between runners with and without PF during early and late stance which may be related to inherent instability in transition phases. Runners with PF had reduced TtC during mid-stance suggesting a more rigid control strategy reflecting the injured state and increased potential for loss of balance. **Table 1.** Results for demographics and time to contact (TtC) for runners with and without plantar fasciitis (PF). * = significant difference (α=0.05).

No Difference In Muscle Excitation Between Runners With And Without Patellofemoral Pain During Prolonged Run
 Savannah L. McLain, Li Li, FACSM, Barry A. Munkasy, Samuel J. Wilson, Klarie Ake, Jessica A. Mutchler. Georgia Southern University, Statesboro, GA.
 Email: sm09149@georgiasouthern.edu
 (No relevant relationships reported)

PURPOSE: To determine if muscle excitation amplitudes differed from beginning, middle, and end of a prolonged run in runners with and without patellofemoral pain. **METHODS:** Five recreationally active female runners with history of running with patellofemoral pain (PFP) were matched to five female runners without lower extremity pain (CON) (PFP: age = 21.2±2.68 years, ht = 1.62±0.10m, mass = 67.45±6.10kg; CON: age = 21.2±1.30 years, ht = 1.66±0.12m, mass = 67.45±7.26kg). Wireless EMG surface electrodes were placed bilaterally on the rectus femoris (RF), vastus medialis oblique (VMO), biceps femoris (BF), and gluteus medius (GMED). EMG data was sampled at 2000Hz. Participants ran at a self-selected pace on a treadmill until they met exertion or pain criteria. EMG signals were passed through a 4th order, zero lag, Butterworth high-pass filter with cut-off at 10Hz, low-pass filter with cut-off at 350Hz, and full wave rectified. Average maximum EMG amplitude for 20 steps from 3 time points (beginning, middle, end) of the run were compared for each group using separate paired samples t-tests for each muscle and group. Alpha level was set at p<0.05. **RESULTS:** No statistically significant differences were observed in EMG amplitude of any muscle for either group when comparing amplitude between participants' first, middle and last trial of the run (PFP: Max_RF: 0.136mV, 0.117mV, 0.100mV, p>0.05; Max_VMO: 0.506mV, 0.464mV, 0.519mV, p>0.05; Max_BF: 0.273mV, 0.273mV, 0.274mV, p>0.05; Max_GMED: 0.121mV, 0.101mV, 0.096mV, p>0.05; CON: Max_RF: 0.103mV, 0.068mV, 0.073mV, p>0.05; Max_VMO: 0.051mV, 0.464mV, 0.052mV, p>0.05; Max_BF: 0.146mV, 0.151mV, 0.149mV, p>0.05; Max_GMED: 0.102mV, 0.086mV, 0.078mV, p>0.05). **CONCLUSION:** Neither groups of runners experienced a significant change in EMG amplitude from beginning, middle and end of a prolonged run. Running with active patellofemoral pain does not appear to change muscle excitation amplitude of the RF, VMO, BF, or GMED during a prolonged run.

Whipping Or Tearing? Mechanisms For The Development Of Achilles Tendinopathy In Runners
 Kevin Aubol, Clare E. Milner, FACSM. Drexel University, Philadelphia, PA. (Sponsor: Clare E. Milner, FACSM)
 Email: kga43@drexel.edu
 (No relevant relationships reported)

Achilles tendinopathy is a common running injury that affects up to 13% of runners. A "whipping" mechanism, in which abnormal rearfoot eversion causes asymmetrical loading of the tendon, has been proposed for the development of Achilles tendinopathy in runners. A second "tearing" mechanism, in which eccentric plantar flexor contractions cause microtears in the Achilles tendon, has also been proposed. However, a clear link between these mechanisms and Achilles tendinopathy has not been demonstrated. **PURPOSE:** To determine if peak rearfoot eversion, duration of rearfoot eversion, peak sagittal plane ankle power absorption, and peak dorsiflexion moment are different between runners with and without a history of Achilles tendinopathy. **METHODS:** 10 male, rearfoot strike runners (34±10 years; 1.79 ± 0.07 m; 81.3 ± 12.6 kg) participated. Five participants had previous or current Achilles tendinopathy and five had no history of Achilles tendon pain. Reflective markers were placed on the trunk, pelvis, legs, and feet. A motion capture system recorded five good trials for each participant running at 3.7 m/s. Variables of interest and effect sizes (r) were calculated to compare groups. **RESULTS:** There was a small effect for peak rearfoot eversion, with previously injured runners exhibiting higher peak rearfoot eversion angles (Table

1). There was also a small effect for the duration of rearfoot eversion, with injured runners remaining in an everted position for longer than the control group. There were no differences between groups in peak power absorption or peak dorsiflexion moment. **CONCLUSION:** In this preliminary study runners with and without Achilles tendinopathy exhibited gait characteristics that provide partial support for the whipping mechanism of injury proposed for Achilles tendinopathy in runners. However, these findings were not consistent with the proposed tearing mechanism of injury.

	Controls Median (IQR)	Previous Injury Median (IQR)	Effect Size (r)
Peak Eversion (°)	8.6 (13)	11.4 (11)	0.30
Duration of eversion (% stance)	71 (45)	87 (61)	0.26
Peak dorsiflexion moment (Nm/kg)	2.2 (0.5)	1.9 (0.8)	0.03
Peak power absorption (watts/kg)	3.8 (1.7)	4.0 (1.0)	0.12

Changes In Coordination And Variability During Running As A Function Of Head Stability Demands
 Jongil Lim¹, Richard Van Emmerik², Joseph Hamill, FACSM².
¹Texas A&M University - San Antonio, San Antonio, TX.
²University of Massachusetts - Amherst, Amherst, MA. (Sponsor: Joseph Hamill, FACSM)
 (No relevant relationships reported)

Stabilization of the head in space is important during running, but less is known about how individuals accomplish the head-in-space equilibrium through segmental and joint coordinative adaptations. **PURPOSE:** To identify changes in segment/joint coordination and its variability in running with increasing head stability requirements. **METHODS:** Fifteen strides from twelve recreational runners (29.67 ± 4.4 years; 1.73 ± 0.08 m; 72.1 ± 13.9 kg) while running on a treadmill at their preferred speed were collected. Head stability demands were manipulated through real-time visual feedback that required head-gaze orientation to maintain within boxes of different sizes, ranging from 21 to 3 degrees of visual angle with 3-degree decrements. Coordination patterns and variability were assessed between head and trunk segments, hip and knee joints, and knee and ankle joints in three cardinal planes, respectively. Mean phase angles and the standard deviation of the phase angles at each individual point of the stance phase were calculated using vector coding and circular statistics. A statistical analysis was performed to detect differences in coordination pattern frequency and waveform of coordination pattern and variability between visual conditions. **RESULTS:** As head stability demands increased, transverse plane head-trunk coordination was more anti-phase (i.e., segments rotating the opposite direction; 3.3%, $p=0.028$), and showed increased head-leading (1.7%, $p=0.001$) and decreased trunk-leading patterns (10.3%, $p=0.015$); for the lower extremity, there was increased in-phase (hip-knee: 5%, $p=0.015$; knee-ankle: 6.4%, $p=0.010$) and decreased anti-phase (hip-knee: 16.7%, $p=0.003$; knee-ankle: 10.8%, $p=0.001$) sagittal plane coordination during the second half of the stance phase. An increase in coordination variability was also observed for lower extremity couplings between the hip and knee and knee and ankle joints. **CONCLUSION:** Overall, the results provide evidence that coordinative adaptations to increasing head stability demands occur throughout the entire body (1) through more independent control of the head relative to the trunk, and (2) by increasing in-phase coordination and variability between lower extremity joints, contributing to the reduction of range of motion in vertical direction.

Associations Between 24-Hour Dietary Intake And Biomechanical Changes During A Long Run: An Exploratory Study
 Cailyn Schroeder, Christopher Casillas, James Becker. Montana State University, Bozeman, MT.
 Email: james.becker4@montana.edu
 (No relevant relationships reported)

Both nutrition and biomechanics play important roles for running and athletic performance. However, to date they have usually been studied separately and there is minimal literature evaluating effects of nutritional status or interventions on biomechanical outcomes. **PURPOSE:** This exploratory study evaluated relationships between nutritional status prior to a long hilly run and changes in running mechanics following the run. **METHODS:** Eight trail runners (5 M/3 F; weekly mileage: 27.6 ± 8.5 miles) ran a 10-mile hilly run which matched the elevation profile of a popular

local trail run. 3D kinematics and ground reaction forces were collected during five-minute level ground running sections prior to and following the run. Changes in spatial temporal parameters, ground reaction forces, and leg stiffness variables from pre to post run were computed for each participant's left leg using Visual3D. Pre-run 24-hour dietary recalls were analyzed for total caloric intake (Tkcals) and percent calories from carbohydrate (%CHO), protein (%PRO), and fat (%FAT). Pearson's correlations were used to assess associations between each nutritional variable and changes in biomechanical variables. **RESULTS:** There were significant associations between %PRO and changes in peak ground reaction force and changes in contact time such that runners with higher %PRO displayed smaller changes in biomechanics (Figure 1). Similar associations were observed between Tkcals and %FAT and changes in vertical center of mass displacement. **CONCLUSIONS:** This preliminary study suggests nutritional status prior to a long run may affect the changes in biomechanics a runner experiences during the run. These biomechanical effects have implications for both performance and injury, and highlight the importance of protein for long distance runners. Additional research is required to evaluate whether manipulating nutrition can be used to manage biomechanical changes associated with long duration running.

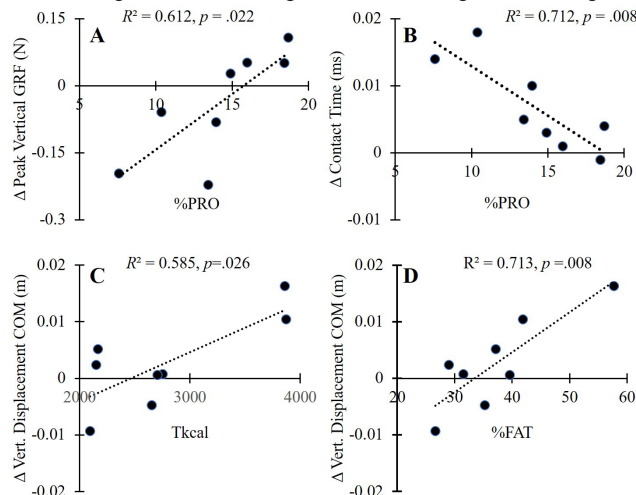

Figure 1. Correlations between % calories from protein (%PRO) and changes in peak vertical ground reaction force (A) and changes in contact time (B). C and D show correlations between total calories (Tkcals) and percent calories from fat (%FAT) and changes in vertical center of mass displacement.

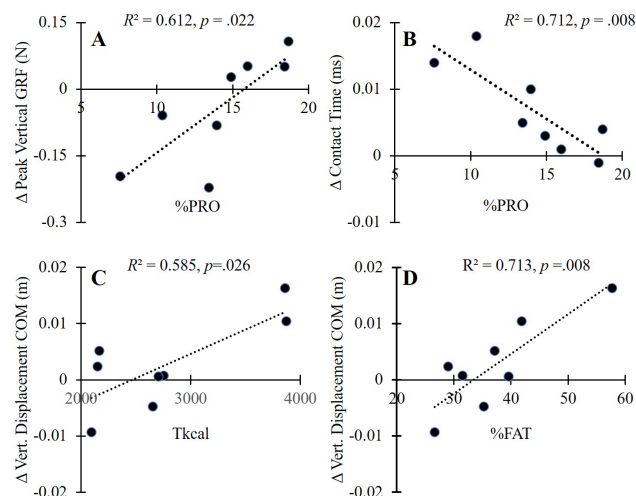

Figure 1. Correlations between % calories from protein (%PRO) and changes in peak vertical ground reaction force (A) and changes in contact time (B). C and D show correlations between total calories (Tkcals) and percent calories from fat (%FAT) and changes in vertical center of mass displacement.

The Relationship Between Forefoot Stiffness And Angular Kinematics During The Early Stance Phase Of Running.

Juan C. Garbalosa, Jose Riofrio, Richard Feinn, Taylor O'Sullivan, Stephen Sharo. *Quinnipiac University, Hamden, CT.*
 Email: juan.garbalosa@quinnipiac.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to determine if a relationship between forefoot stiffness and intersegmental foot kinematics exists. We hypothesized runners with high stiffness values would exhibit decrease foot motion. **METHODS:** A convenience sample of 20 asymptomatic recreational runners participated in this study. At the completion of a warm-up protocol, subjects underwent a measurement of their non-weight bearing midfoot torsional stiffness using a foot torsion measurement device. Retroreflective markers were placed over select bony landmarks located on the subject's lower legs and feet and then recorded using an 18-camera motion analysis system sampling at 240 Hz while running at their self-selected speed. Data analysis: Torsion-angle curves were fit with a one-degree polynomial and the intercepts and first term coefficients (FTC) recorded. The rearfoot and forefoot three-dimensional angular kinematics of the first third of the stance phase of the running trials were obtained for each subject. A linear regression model was used to assess the relationship between the maximum eversion and inversion rearfoot and forefoot angles and the FTC. The statistical level of significance for this study was set at the $p = .05$ level.

RESULTS: The mean eversion and inversion FTC were -0.44 ± 0.44 and -0.08 ± 0.20 Nm/degree. The mean maximum rearfoot eversion and inversion angles were 2.0 ± 2.1 and 1 ± 2.3 degrees, respectively. The mean maximum forefoot inversion and eversion angles were 1.0 ± 2.4 and 1.0 ± 2.3 degrees, respectively. The regression model did not reveal a significant relationship ($p > .05$) between the eversion and inversion FTC and the kinematic variables.

CONCLUSIONS: During the first third of the stance phase of running passive stiffness of the foot does not appear to be related to dynamic motion.

Persistence Of Altered Kinematics Following A Typical Training Run At 24hrs

Sherveen Riazati, Nick Caplan, Phillip Hayes. *Northumbria University, Newcastle upon Tyne, United Kingdom.* (Sponsor: Prof. Florentina Hettinga, FACSM)
 Email: sherveen.riazati@northumbria.ac.uk
 (No relevant relationships reported)

Running participation has increased since the 1970's, concomitant with the rise in popularity has been the rise in running related injuries. Epidemiological studies have reported 2.5 to 33.0 injuries for every 1000 hours of running, with most common injuries being overuse knee injuries. There is a common consensus that altered hip and knee kinematics are risk factors for developing overuse injuries. Previously we demonstrated altered gait kinematics as result of fatigue following a high intensity interval training run (HIIT). These fatigue induced alterations in kinematics could place runners at greater risk of developing an overuse injury. To date, the time course of recovery for gait kinematics is unknown. If these gait changes remain at the onset of the next training run this could be a precursor to overuse injury. **PURPOSE:** To examine the time course of kinematic changes immediately after and 24hr post HIIT. **METHODS:** Twenty (10F, 10M) healthy recreational runners performed a HIIT session consisting of six repetitions of 800 meters, each run at $1\text{km}\cdot\text{h}^{-1}$ under the speed at V_{O_2} max, with a 1:1 work: rest ratio. Kinematics were examined during a 6-minute, medium intensity run, performed at halfway between the speeds at lactate threshold and lactate turnpoint. The 6-min run was performed pre, post, and 24hr post HIIT. Maximum angle and range of motion (RoM) of the hip and knee during ground contact were analysed in sagittal and frontal planes. One way repeated measures ANOVA was performed to assess changes over time. **RESULTS:** Hip frontal angles were significantly increased with time for both maximum angles ($P < 0.001$) and RoM ($P = 0.001$). Post hoc analysis revealed a significant increase in maximum hip adduction angle immediately post ($P < 0.001$, $d = 0.91$) and at 24hr post ($P < 0.001$, $d = 0.86$) compared to pre. Hip frontal RoM was also increased significantly at post ($P < 0.001$, $d = 0.85$) and at 24hr ($P < 0.001$, $d = 0.74$). Knee kinematics were affected by time for maximum angle of knee frontal plane ($P = 0.046$) and sagittal plane knee RoM ($P = 0.015$). However, there was no presence of altered knee kinematics at 24hr. **CONCLUSION:** The HIIT session induced kinematic alterations to the hip frontal angles. In some runners these alterations were still present 24 hours after HIIT. For these runners, this could increase the risk of developing overuse injuries.

Effects Of Foot Rotation On Knee Joint Reaction Forces During Running

Hunter Jared Bennett¹, Kevin A. Valenzuela², Joshua T. Weinhandl³. ¹*Old Dominion University, Norfolk, VA.* ²*California State University Long Beach, Long Beach, AR.* ³*The University of Tennessee, Knoxville, TN.*
 Email: hjbennet@odu.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to examine the effects of internal and external foot rotation on knee joint reaction forces during running.

METHODS: Motion capture and force data were recorded on nineteen healthy adult runners (22.3 ± 4.0 years, 67.99 ± 10.27 kg, and 1.77 ± 0.10 m) running at 3.5 m/s with normal and maximal comfortable external (EXT) and internal (INT) foot rotation. Musculoskeletal simulations were performed using the Rajagopal 2015 model and OpenSim (SimTK). All data were low pass filtered at 10 Hz and normalized to a full stride (stance: 0-36% & swing: 37-100% stride). Models were scaled to each subject's anthropometric parameters. Inverse dynamics were derived by combining inverse kinematics and force data. Muscle excitations were derived using Static Optimization, including muscle physiology parameters. Joint Reaction Forces were obtained by combining inverse kinematics, force data, and muscle excitations. Within-subjects ANOVAs via Statistical Parametric Mapping were used to determine differences in resultant knee joint reaction force waveforms.

RESULTS: The EXT condition decreased early stance (0-2% stride) and late swing (92-100% stride) phase forces, but increased forces during early swing (44-46% phase) compared to normal. The INT condition reduced forces during very late swing phase (92-94% stride). The EXT reduced forces during early stance (0-1% stride) and late swing (97-100% stride) compared to INT.

CONCLUSIONS: Despite the known success of altered foot rotation on reducing external knee abduction moments during walking and running, knee forces were only reduced during low-loading portions of running strides. Thus, it appears altered foot rotations does not improve knee loading during running.

Muscular Not Skeletal Components Of Leg Stiffness Are Significantly Correlated With Associated Biomechanical Variables During Running

Jay Hinton¹, D.S. Blaise Williams², Alexis K. Nelson¹, Hailey B. Fong¹, Max R. Paquette¹, Douglas W. Powell, FACSM¹. ¹*University of Memphis, Memphis, TN.* ²*Nike Sport Research Laboratory, Beaverton, OR.* (Sponsor: Dr. Douglas W. Powell, FACSM)
 (No relevant relationships reported)

Muscular (kMusc) and skeletal (kSkel) components of leg stiffness have been previously related to injury patterns in runners [1]. Though these components mirror proposed injury mechanisms in runners, their relationship to underlying biomechanical variables remains unclear. **PURPOSE:** to evaluate the association between components of leg stiffness (kMusc & kSkel) with common biomechanical variables of muscular (joint work) and skeletal loading (joint reaction forces) during a running task. **METHODS:** Thirteen recreational runners (8 male, 5 female) performed ten over ground running trials at 3.35 m/s ($\pm 5\%$) in each of four conditions with varying shoe and strike patterns. Kinematics and ground reaction forces (GRFs) were recorded using an 8-camera motion capture system (240 Hz, Qualisys) and force platform (1200 Hz, OR-7, AMTI). Visual3D (C-Motion) was used to calculate joint powers and compressive joint reaction forces (JRFs). MATLAB was used to calculate negative joint work values and stiffness variables. kMusc and kSkel were calculated as previously reported [1]. Prism 8.0 (GraphPad) was used to perform correlation analyses between muscular and skeletal contributions to load attenuation. **RESULTS:** kMusc had moderate and weak relationships with lower extremity work ($p < 0.01$; $r = 0.55$) and knee joint work ($p = 0.01$; $r = 0.32$). Weak correlations existed between kSkel and ankle ($p = 0.25$; $r = -0.10$), knee ($p = 0.17$; $r = 0.14$) and hip joint reaction forces ($p = 0.46$; $r = 0.01$). **CONCLUSIONS:** These data revealed moderate associations between kMusc and negative work values suggesting that kMusc is proportional to muscular contributions to load attenuation. JRFs had weak associations with kSkel, suggesting kSkel may not represent skeletal loading. These findings suggest this simplistic model may be insufficient to describe muscular and skeletal contributions to load attenuation.

[1] Powell, Paquette & Williams, 2017.

in the running group ran at least 15 miles/week, while participants in the resistance training and cycling/swimming group ran at least 3 miles/week. Running kinematics were captured using a 10-camera motion capture system while participants ran at a controlled pace of 3.5 m/s ($\pm 5\%$) over a 10-m runway with force platforms collecting kinetic data. Five successful trials were chosen for analysis. A one-way ANOVA assessed differences in mean kinematic and kinetic variables of interest between physical activity groups ($\alpha < 0.05$). **RESULTS:** Mean values for gait variables during the stance phase are shown in Table 2. **CONCLUSION:** Preliminary data shows no differences between activity groups, suggesting that participation in physical activity helps maintain healthy movement patterns in older adults. As the study continues we will be able to ascertain whether this lack of difference is a result of our small current sample size or reflective of the participants' primary form of physical activity.

Table 1: Participant demographics.

	Running	Resistance Training	Cycling/Swimming
Age	54.20 \pm 5.81	48.40 \pm 3.91	56.40 \pm 6.69
Height (m)	1.76 \pm 0.11	1.69 \pm 0.11	1.69 \pm 0.15
Mass (kg)	71.69 \pm 12.88	67.97 \pm 11.01	74.69 \pm 17.54
BMI (kg/m ²)	22.84 \pm 1.76	23.80 \pm 2.33	26.24 \pm 5.10
PBF (%)	21.40 \pm 5.80	20.10 \pm 4.54	27.86 \pm 16.46
Days/week	5.00 \pm 1.22	4.80 \pm 1.10	4.60 \pm 0.89
Miles/week	41.00 \pm 14.32	6.20 \pm 4.49	9.20 \pm 4.09

Mean \pm standard deviation; m: meters, kg: kilogram; BMI: body mass index; PBF: percent body fat; days/week: number of days participating in respective primary activity.

Table 2: Kinematics and kinetics during the stance phase of gait.

	Running	Resistance Training	Cycling/Swimming
Ankle ROM ($^{\circ}$)	20.66 \pm 2.31	17.18 \pm 4.85	20.02 \pm 5.63
Knee ROM ($^{\circ}$)	20.99 \pm 1.11	24.29 \pm 4.15	27.25 \pm 7.29
Hip ROM ($^{\circ}$)	39.41 \pm 6.27	43.91 \pm 3.71	39.25 \pm 6.74

Normalizing Running Power By Muscle CSA Increases Variance Explained Compared To Metabolic Power
 Mason J. Coppi, Scott Murr, Eric Sobolewski, Randolph E. Hutchison, Alec Whyte, Jake T. Ogden, Frank Lara, Trent Mandato. *Furman University, Greenville, SC.* (Sponsor: Anthony Caterisano, FACSM)
 Email: randolph.hutchison@furman.edu
 (No relevant relationships reported)

Running pace is one of the primary measures of running intensity, however, variations in grade limit quantifying intensity solely based on pace. Cross sectional area (CSA) of the vastus lateralis is a key determinant in running pace. With the advent of wearable running power meters, runners can assess the metabolic demand inclusive of pace and grade. The research of CSA on metabolic demand in running with wearables is currently limited. **PURPOSE:** The purpose of this study was to compare running power to metabolic power of running submaximally at various speeds and inclinations. Additionally, correlations were compared at a group level with and without normalization to CSA. **METHODS:** Four collegiate cross-country runners

(male n=1, age=22yrs, weight=72.6 kg, height=183 cm; female n=3, age=19.67±0.58 yrs, weight=54.07±2.29 kg, height=164.33±10.26 cm) participated in 10 trials of steady-state, submaximal running at different speeds and inclinations. The CSA of the subject's vastus lateralis and rectus femoris was measured by use of ultrasound (GE LOGIQ e Series). Ventilatory measures and heart rate (HR) were measured with a portable breath by breath analyzer (COSMED K5). Running speed was paced by a cyclist using a speedometer. Pearson Correlation Coefficients between metabolic and running power (normalized by total CSA) were calculated for all subjects, individually as well as combined.

RESULTS: There were statistically significant, strong positive correlations between metabolic power and running power (normalized and non-normalized) for the collegiate cross country runners, both individual (Table 1) and as a group, ($r_{p,CSA} = .910$ $P < 0.001$, $r_s = .602$ $P < 0.001$).

CONCLUSIONS: The results support that predicted running power is positively related to metabolic power, which indicates a strong relationship with running intensity. Additionally, normalizing running power to CSA improves correlation and increases the explanation of variability (r^2) from 36% to 83%.

Subject	Correlation Coefficient (r)	Significance
1	0.83	P<0.01
2	0.99	P<0.001
3	0.99	P<0.001
4	0.93	P<0.001
Combined, non-normalized	0.60	P<0.001
Combined, CSA-normalized	0.91	P<0.001

Characterization Of Fatigue In A Short Bout Of Running

Yunae Lee, Erin Butler, Jeff Knight, Luke Montzingo. *Under Armour, Austin, TX.* (Sponsor: Brian Mcfarlin, FACSM)
(No relevant relationships reported)

All runners experience physiological fatigue during a run. Research shows physiological stress induced by fatigue influences changes in running biomechanics. However, past studies have focused on a limited number of kinematic variables during fatigue. To understand the interrelationship between a plurality of kinematic variables, a study was conducted to observe changes in stride length (SL), ground contact time (GCT), foot strike angle (FSA), and cadence (CAD). It was hypothesized fatigue would yield a decreased CAD, increased GCT and SL, and shift subjects to a more rear-foot FSA. **PURPOSE:** To examine the influence of physiological fatigue on running biomechanics during a short bout of high-intensity running. **METHODS:** Male and female athletes of all levels (n=36; 15 female; 33 ± 9 years; 70.11 ± 13.66 kg; 171.37 ± 9.75 cm) participated in a 20-minute treadmill fatiguing protocol. Subjects first ran 5 minutes at their preferred pace (speed one), followed by ten minutes at a fatiguing pace (speed two), and ended with five minutes at speed one. Speed two was .67-.89 m/s faster than speed one, near estimated vVO_{2max} . Kinematic time series data from a shoe embedded accelerometer was collected for the following metrics: CAD, SL, GCT, and FSA. The first 30 seconds of speed two (fatigue start) was analyzed and compared to the last 30 seconds of speed two (fatigue end). Subjects were considered fatigued when heart rate met or exceeded 90% age predicted max and RPE ≥ 17. Significant differences between fatigue start and fatigue end were tested with a varied samples t-test. **RESULTS:** Significant differences were identified between fatigue start and fatigue end for CAD (173.36±13.91 vs 169.92±11.99 steps/min, $p < 0.001$), SL (2.45±0.34 vs 2.50±0.34 meters, $p = 0.003$), and GCT (279.61±44.25 vs 285.25±44.44 ms, $p = 0.004$). CAD decreased while SL and GCT increased. No significant difference was observed for FSA. **CONCLUSION:** This study demonstrated biomechanical changes in running form from the beginning to the end of a short, high-intensity fatiguing run. The direction of change for cadence, stride length, and ground contact time confirmed the hypothesis. Changes in foot strike angle were not confirmed.

Anthropometric And Kinematic Predictors Of Base Of Gait During Running

Mikel R. Stiffler-Joachim, Seraphina G. Provenzano, Jennifer L. Sanfilippo, Bryan C. Heiderscheit. *UW-Madison, Madison, WI.*
 Email: joachim@ortho.wisc.edu
(No relevant relationships reported)

A narrow base of gait (BOG) during running, such that the foot crosses contralateral to the body's line of gravity, has been implicated as a cause of iliotibial band syndrome and patellofemoral pain. BOG has been shown to vary by sex and running speed, but

it is unknown if body anthropometric and running kinematic measures predict BOG. Determining predictors of BOG will clarify if BOG is a result of non-modifiable anthropometric factors or biomechanical factors, which could be modified using targeted interventions. **PURPOSE:** To determine if BOG at midstance during running can be predicted by anthropometric or kinematic measures. **METHODS:** Whole body kinematics were obtained for 71 Division I cross country runners (30 males) during treadmill running at preferred speed. Athletes were healthy with no history of stress fracture 3 months before testing or any history of lower extremity surgery. Anthropometric measures from each athlete were obtained from whole body dual-energy X-ray absorptiometry scans: greater trochanteric (GTR) and hip joint center width; leg and femur length. Kinematic measures during stance phase included: peak lateral pelvic drop, hip adduction (H_{ADD}), knee flexion (K_{FLEX}); vertical excursion of center of mass ($vCOM$); anterior-posterior distance from heel to COM at initial contact. Correlations between predictors and BOG were calculated, with variables moderately correlated or better ($|r| \geq 0.3$) included in subsequent analyses. Data from both limbs were included in a forward, stepwise regression to determine predictors of BOG, controlling for sex and speed. **RESULTS:** Stride length, $vCOM$, peak K_{FLEX} and H_{ADD} , GTR width, and leg and femur length ($|r| = 0.32 - 0.51$) were entered into the model. The model with the best overall fit included all predictors except leg length ($R^2 = 0.383$, BIC: -32.1). The strongest predictors were GTR width ($\beta = -0.27$), $vCOM$, ($\beta = -0.18$), and peak H_{ADD} ($\beta = -0.17$). **CONCLUSIONS:** Biomechanical and anthropometric measures explain less than 40% of the variance in BOG. Given that GTR width is the strongest predictor of BOG and is non-modifiable, BOG appears to be largely influenced by an individual's anthropometrics. Conversely, $vCOM$ and peak HADD are modifiable through gait retraining strategies such as step rate modification and may be targeted in those where narrow BOG is a concern.

Cost Of Transport In Ultra-runners Utilizing Hand Bottle Vs. Hydration Pack

Brooke W. Haugen¹, Paolo Taboga², Roberto Quintana¹. ¹Human Performance Research Lab, CSU-Sacramento, Sacramento, CA. ²Biomechanics Lab, CSU-Sacramento, Sacramento, CA.
 Email: bwhaugen13@gmail.com
(No relevant relationships reported)

Over the last 10 years, ultra-marathon running events have become increasingly popular. For these longer distances, it is common for runners to carry hydration devices with them. How different water carrying devices impact cost of transport (CoT) during running is unknown.

PURPOSE: To examine differences in CoT in trained ultrarunners utilizing two popular hydration devices filled with various amounts of water.

METHODS: Six ultra-marathon trained runners (5 males, 1 female) participated in this study after obtaining informed consent. Each subject completed six 10 min running trials at 15% below their lactate threshold over two days: one baseline trial (no water), two trials with a hand bottle (0.25 and 0.5 kg of water) and three trials with a hydration pack (0.5, 1.0 and 1.5 kg of water) on their back. Each subject's running trials were randomized utilizing a Latin Square design. For each trial, we analyzed VO_2 (ml/kg/min) and RER to obtain 2 minutes of steady state data to calculate CoT (J/kg/m). We used a linear mixed model to analyze the effects of water mass and hydration device on CoT.

RESULTS: We found a statistically significant effect of water mass on CoT: every 1 kg of additional water mass increases CoT by 0.09 J/kg/m (1.92%, $p = 0.03$), but hydration device had no significant effect on CoT ($p = 0.31$) (see Figure 1).

CONCLUSIONS: Our preliminary findings indicate that CoT increases by 1.92% for every additional 1 kg of water mass carried. This increase in CoT could have significant negative effects on ultramarathon running performance.

Figure 1. Cost of transport (CoT, J/kg/m) as a function of water mass (kg) carried. The regression line is calculated using a linear mixed model: each subject was classified as a random effect; water mass was classified as fixed-effect; and CoT as the outcome variable.

Influence Of Leg Stiffness And Its Effect On Performance During Acceleration And Constant Speed Phases Of Sprinting

Wei Zhuang, Keyi Yin, Yu Liu. *school of kinesiology, Shanghai, China.*
 Email: zhuangweisus@outlook.com
 (No relevant relationships reported)

Evidence between leg stiffness and varying sprint speed remains inconclusive. Some studies indicate that with the increase speed, from low to medium, both vertical stiffness and leg stiffness increase which may lead to improved push-off force during a sprint. Others have shown that leg stiffness remains relatively unchanged with the increment of speed. Some recent evidence suggests that muscular strategies of high-speed sprinting may be different.

PURPOSE: The purposes of this study are to: (a) determine differences in leg stiffness during acceleration and constant speed phases in sprinting, (b) examine the association between leg stiffness and kinematic and kinetic characteristics during each phase of sprinting.

METHODS: 11 sprinters (Height 1.77 ± 0.05 cm; Weight 69 ± 0.55 kg; Personal Best 11.17 ± 0.23 s) from Shanghai University of Sport participated in the study. 12 cameras were used to capture the kinematic data (200HZ) and three force plates were placed in the runway to ascertain kinetic data (1000HZ). The starting line of sprinting was set 12 and 40 meters ahead of force plates allowing sufficient leadway for acceleration and constant speed phases when they reached the force plates. Paired samples t tests and correlation analyses were used to analyze leg stiffness and kinematic and kinetic data ascertained under each running phase.

RESULTS: There was a significant difference in leg stiffness between constant speed phase and acceleration phase of sprinting (15.11 ± 2.00 kN/m versus 12.54 ± 1.98 kN/m, $p = 0.001$). No difference was observed in vertical stiffness between the two phases. Leg stiffness during the constant speed phase was significantly correlated with vertical ground reaction force (normalized by body weight) and contact time ($r = -0.754$; $r = -0.751$). Similar results on leg stiffness were observed during the acceleration phase ($r = -0.849$; $r = -0.686$).

CONCLUSION: During the acceleration phase of sprinting, leg stiffness was more pronounced than constant speed phase. Leg stiffness in the two speed phases were correlated with contact time and vertical ground reaction force.

The Influence Of Hamstring Muscle-tendon Stiffness On Isolated And Dynamic Velocity Based Parameters

Sean P. Langan, Jadeon D. Carreker, Thomas Murphy, George J. Davies, Bryan L. Riemann. *Georgia Southern University (Armstrong), Savannah, GA.*
 (No relevant relationships reported)

Previous research has demonstrated sex differences in active hamstring muscle-tendon stiffness as well as associations between stiffness and landing biomechanics and architectural tissue properties. Little is known whether active stiffness relates to other measures of muscle function (i.e., maximum voluntary isometric contraction [MVIC], isotonic dynamometry) and performance (i.e., sprinting).

PURPOSE: To conduct a pilot study examining the relationship between active hamstring muscle-tendon stiffness and isometric torque production, isotonic velocity development, and sprint velocity. A secondary research interest was to examine the relationship between the isotonic velocity parameters and sprint performance.

METHODS: Nine recreationally active and healthy subjects (7 males, 2 females) (24 ± 3 years) completed an MVIC for the hamstrings (30° knee flexion) followed by three 40m sprint trials using an infrared timing gate system (Brower, Draper, UT). At least 48 hours later, subjects completed a measure of hamstring muscle-tendon stiffness (damped oscillatory technique) and an isotonic knee flexion test on a fixed dynamometer (Biodex, Shirley, NY). The isotonic test began at 90° of knee flexion and was eccentric/concentric through a 90° arc of motion with subjects lying prone. Eccentric velocity was set at $180^\circ/s$ and concentric torque was set at 25% of MVIC. Bivariate correlations were conducted between stiffness, MVIC (normalized to body mass), sprint times, time to peak velocity, rate of velocity development (RVD, 0-100ms), and rebound time ($-50^\circ/s$ to $+50^\circ/s$).

RESULTS: Stiffness (24.3 ± 11.7 Nm/kg) was only significantly related ($r = .681$, $P = .043$) to MVIC (1.48 ± 0.23 Nm/kg). Stiffness was not significantly related to rebound time (0.076 ± 0.026 s) ($r = -.354$, $P = .350$), time to peak velocity (0.214 ± 0.034 s) ($r = -.285$, $P = .457$), RVD_{0-100} ($1314.64 \pm 222.30^\circ/s^2$) ($r = -.336$, $P = .377$), or sprint velocities (5.90 ± 0.56 m/s) ($r = .248$, $P = .521$). Rebound time ($r = -.535$, $P = .138$) and RVD_{0-100} ($r = -.436$, $P = .241$) were not significantly related to sprint times.

CONCLUSIONS: Although only the association between stiffness and normalized MVIC reached statistical significance, the magnitude of the other observed relationships provides impetus for further study with a larger sample size.

Effects Of Minimal, Traditional, And Highly Cushioned Shoes On Injury-related Biomechanics In Rear And Non-rearfoot Strike Runners

Richard T. Beltran¹, Jake A. Melaro¹, Megan R. Ryan¹, Isabel Moore², Max R. Paquette¹. ¹University of Memphis, Memphis, TN. ²Cardiff Metropolitan University, Cardiff, United Kingdom. (Sponsor: Douglas W. Powell, FACSM)
 Email: rtbltran@memphis.edu
 (No relevant relationships reported)

Running barefoot, in minimal shoes, or traditional shoes alters certain injury-related biomechanical variables and these footwear effects can be influenced by foot strike pattern. It is unclear however how highly cushioned shoes might alter this interaction.

PURPOSE: Given the increasing popularity in highly cushioned footwear in runners, this study assessed the interaction of footwear and foot strike pattern on injury-related biomechanical variables in experienced runners. **METHODS:** Six rear (RFS) and seven non-rearfoot strike (NRFS) experienced runners completed five running trials at 3.5 m/s ($\pm 5\%$) in minimal (MSH), standard (SH) and high cushioned (HC) shoes. A mixed-design repeated measures ANOVA was used to test interaction effects for all injury-related variables. Paired t-tests were used to decipher any interaction effect and Cohen's *d* effect sizes were computed to assess mean difference magnitudes.

Given the preliminary nature of this work and the small sample size, alpha level was set to 0.1. **RESULTS:** Strike index confirmed the different strike patterns while running in SH between RFS ($15.2 \pm 3.1\%$) and NRFS ($10.2 \pm 11.8\%$) groups ($p < 0.001$). Interaction effects were not observed for any of the variables except for peak eversion velocity ($p = 0.1$) and instantaneous vertical loading rate (IVLR; $p = 0.1$) (Figure 1). Main footwear effects were observed for IVLR ($p = 0.004$) and peak eversion velocity ($p = 0.01$). Main foot strike effects were observed for step length ($p = 0.041$), strike index ($p = 0.00$), and IVLR ($p = 0.00$). **CONCLUSION:** Similar to prior research, these current preliminary findings suggest there might be an interaction between foot strike and footwear in experienced runners for peak eversion velocity and IVLR. Thus, if these biomechanical variables are of interest to scientists or clinicians, these findings suggest that footwear type and strike pattern should both be considered in research or return to running programs.

Figure 1. Instantaneous vertical loading rate (A: IVLR) and peak eversion velocity (B) in the three footwear conditions in rear (RFS; black) and non-rearfoot strike (NRFS; red) runners. *: foot strike group difference within footwear; #: footwear difference within foot strike group ($p < 0.1$).

How does footwear impact stride characteristics in younger and older runners?

Kelsey Klug, Brianne Borgia, Julia Freedman Silvernail
 University of Nevada, Las Vegas, Las Vegas, NV
 Running is an increasingly popular form of exercise among adults due to the positive influence exercise has on health. Currently, little is known about how different types of footwear effect gait mechanics in experienced runners. **PURPOSE:** The purpose of this study was to examine how different types of running footwear impacted stride characteristics in younger and older experienced runners. **METHODS:** Five older adults (Age: 56 ± 7.28 ; Mass: 77.96 ± 10.92 ; Height: 1.75 ± 0.09 ; PBF: 21.78 ± 5.13 ; Miles/week: 25 ± 5.77) and five younger adults (Age: 30.80 ± 3.32 ; PBF: 24.02 ± 3.31 ; Miles/week: 23 ± 6.08) participated in this investigation. Participants were provided with a neutral shoe and a maximal cushioning shoe in their self-reported size. The participants own running shoes served as a third footwear condition. Participants

ran at a controlled pace of 4.0 m/s ($\pm 5\%$) over a 10-m runway with force platforms collecting kinetic data. Initial contact and toe off were determined from the vertical GRF using a 30N threshold from which stance time, swing time, step width and stride length were calculated. Differences in mean stride characteristics were analyzed using a 2x3 (group x shoe) mixed analysis of variance ($\alpha < 0.05$). **RESULTS:** Mean values for variables of interest are shown in Table 1. No comparisons were significant, with all p-values greater than 0.05. **CONCLUSION:** There were not differences observed between groups or footwear condition suggesting participants maintained their preferred movement in all three shoes.

Table 1. Stride Characteristics

	Neutral Shoe		Maximal Shoe		Own Shoe	
	Young	Older	Young	Older	Young	Older
Stance time (s)	0.19 (0.01)	0.21(0.03)	0.19 (0.02)	0.21(0.02)	0.16(0.04)	0.20(0.02)
Swing time (s)	0.43(0.03)	0.44(0.03)	0.42(0.01)	0.43(0.04)	0.44(0.03)	0.42(0.02)
Step width (m)	0.07(0.02)	0.15(0.18)	0.06(0.02)	0.16(0.19)	0.08(0.01)	0.15(0.18)
Stride length (m)	2.92 (0.14)	2.90(0.20)	2.89(0.14)	2.83(0.26)	2.70(0.40)	2.92(0.23)

Mean (standard deviation) of stride characteristics during gait. s: seconds; m: meters.

Locomotion Pattern Alters Apparent Joint Stiffness During Unloaded And Loaded Bipedal Ambulatory Tasks In Women

Kellen T. Krajewski, Camille C. Johnson, Dennis E. Dever, Nizam U. Ahamed, Qi Mi, William J. Anderst, Chris Connaboy. *University of Pittsburgh, Pittsburgh, PA.*
 Email: ktk20@pitt.edu
(No relevant relationships reported)

Soldiers often perform bipedal ambulatory tasks with load carriage. During marching they are encouraged to use a walk pattern instead of running (RN) despite translating at a velocity above their gait transition (GTV), known as forced marching (FM). Apparent joint stiffness provides an opportunity to quantify the modulation of lower extremity elasticity during dynamic activity in regard to joint loading. Moreover, joint stiffness potentially has implications on mechanical efficiency. However, little is known how load magnitude and locomotion pattern affects joint stiffness at relative velocities. **PURPOSE:** To determine interactive effects of load magnitude and locomotion on lower extremity joint stiffness in women.

METHODS: Twelve healthy females (24.75 \pm 2.17 years, 60.98 \pm 9.74kg) completed 2 testing sessions collecting kinematic (100 Hz) and kinetic (1000 Hz) data. Subjects wore combat boots and a dual-sided weighted vest. Trials were conducted at body weight (BW) and loaded; +25%, +45%. At each load, 2 locomotion types (RN and FM) were performed at 10% above their GTV. Joint angles (θ) were relative and moments (M) normalized to system weight. Joint stiffness (K) [sagittal plane] calculated as $\Delta M_{joint} / \Delta \theta_{joint}$ during the braking portion of stance phase. Multifactorial RMANOVA, load by locomotion (3x2), were conducted on each K for each limb (dominant [DOM] & nondominant [NON]) separately. Bonferroni-corrected pairwise comparisons were conducted when necessary ($\alpha < 0.05$).

RESULTS: K_{ankle} had a main effect of locomotion (DOM: $p = .02$, NON: $p = .002$); RN (.81 \pm .22 Nm/kg/°) ~82.5% greater than FM (.14 \pm .04 Nm/kg/°) for both limbs. K_{knee} had a main effect of locomotion (DOM: $p < .001$, NON: $p < .001$); RN (.09 \pm .01 Nm/kg/°) ~80.5% greater than FM (.03 \pm .004 Nm/kg/°) for both limbs. For K_{hip} , had a main effect of load (NON: $p = .01$); +45% ~10% less than +25%.

CONCLUSIONS: Ankle and knee joint stiffness were not significantly altered by changes in load magnitude, demonstrating the importance of locomotion pattern on modulating apparent joint stiffness. Unlike the ankle and knee, the hip may only mediate lower extremity stiffness with the addition of load. Greater observed joint stiffness during RN may exhibit the greater elastic energy potential that can be leveraged for energy absorption and horizontal propulsion compared to FM.

The Influence Of Maximal And Minimal Shoes On Walking Biomechanics In Older Individuals

Christine D. Pollard¹, J.J. Hannigan². ¹Oregon State University-Cascades, Bend, OR. ²San Jose State University, San Jose, CA.
 Email: christine.pollard@osucascades.edu
(No relevant relationships reported)

Older individuals frequently walk as a means for exercise and often wear running shoes during this activity. Recently there has been increased popularity in older individuals wearing maximal running shoes during walking. Maximal running shoes are unique because they are comprised of a highly cushioned midsole in both the rearfoot and forefoot that is supposed to improve shock attenuation. Minimal running shoes with little cushioning are also used in this population to improve proprioception and balance. Loading in the frontal plane is of particular interest for older individuals since it has been associated with increased risk of knee osteoarthritis. Little is currently known about how maximal and minimal shoes influence walking biomechanics in any age group.

PURPOSE: To examine the influence of maximal and minimal running shoes on walking biomechanics in older individuals. **METHODS:** Walking biomechanics were collected on 16 female participants (age range: 51 – 64 years) using an 8-camera Vicon motion capture system and two embedded force plates. 3D kinematics and kinetics were collected while subjects walked along a 10-meter runway in three different footwear conditions (MAX, MIN, TRAD). Variables of interest included the 1st and 2nd peak of the vertical ground reaction force (F_{z1} , F_{z2}), the instantaneous vertical loading rate (IVLR), peak ankle eversion and knee varus angles, and the peak external ankle eversion and knee varus moments. Differences were determined using a repeated measures ANOVA. **RESULTS:** The external knee varus moment was significantly higher in the maximal shoe compared to the traditional shoe (MAX: 0.55 \pm 0.16 Nm/kg, TRAD: 0.49 \pm 0.14 Nm/kg, $p = .005$). The IVLR was significantly higher in the minimal shoe compared to the traditional shoe (MIN: 30.4 \pm 3.4 BW/s, TRAD: 21.8 \pm 1.8 BW/s, $p < .001$). No other significant differences were found for the variables of interest. **CONCLUSION:** The maximal shoe was found to increase the external knee varus moment, which has been linked to increased pain and disease progression in knee osteoarthritis. The IVLR was significantly higher in the minimal shoe, which has also been linked to injury. Based on these findings, there are no clear advantages to wearing a maximal or minimal shoe during walking, and doing so may be detrimental to injury risk. No grant support was provided.

Dual Task Interference During Walking After Ten Days Of Complete Physical Inactivity

Uros Marusic¹, Marco Narici², Rado Pisol¹. ¹Science and research centre Koper, Koper, Slovenia. ²University of Padua, Padua, Italy.
(No relevant relationships reported)

Prolonged physical inactivity or immobilization after sports injuries and/or surgery can lead to severe cognitive and motor disorders that prevent rapid recovery and lead to future falls. Previous studies have shown that gait control provides the demand for cognitive centers of the brain and that dual-task assessments may indicate an increased risk of falling or a protection strategy to prevent falls. **PURPOSE:** To determine to which extent walking and walking while texting ability deteriorates after prolonged physical inactivity. **METHODS:** Ten healthy young volunteers successfully completed 10 days of horizontal bed rest with 24h video and medical monitoring. Gait speed parameter was obtained with the 2D OptoGait system (Microgate, Italy, EU) under four different conditions in a random order: self-selected and fast paced walking condition with (dual-task) and without (single-task) typing on the smartphone. **RESULTS:** Ten days of horizontal bed rest had no significant impact on the self-selected gait speed in single- (-5.7%; $p = 0.190$) and dual-task conditions (-4.0%; $p = 0.339$). In contrast, bed rest significantly decreased gait speed in fast paced walking condition in single- (-9.9%; $p = 0.009$) and dual-task conditions (-10.3%; $p = 0.002$). **CONCLUSION:** Our results show that bed rest reduces gait performance and that the effects are greater for tasks that require more attentional resources - tasks with higher complexity. The results can be used for the future development of effective rehabilitation countermeasures. Supported by ASI, MARS-PRE Project, n. DC-VUM-2017-006.

Walking Biomechanics Associated With Patellofemoral Pain In Sedentary And Active Emerging Adult Women

Jillian L. Hawkins, Clare E. Milner, FACSM. *Drexel University, Philadelphia, PA.* (Sponsor: Clare Milner, FACSM)
 (No relevant relationships reported)

About 50% of emerging adults do not meet the national physical activity recommendations. Risk of injury, like patellofemoral pain (PFP) during walking, may be a barrier to meeting the physical activity recommendations for sedentary emerging adults. **PURPOSE:** To determine if sedentary emerging adult women had walking biomechanics related to PFP compared to active emerging adult women. **METHODS:** As part of a larger study, 26 (12 sedentary, 14 active) emerging adult women (age:22(3) years; height: 1.58(0.08) m; mass: 58.4(8.7) kg) participated in the study. Anatomical and tracking retro-reflective markers were placed on body segments to record movement. Participants completed 5 good walking trials at 1.4 m/s (\pm 5%). Three-dimensional gait analysis was performed using motion capture sampling at 200 Hz and force platforms sampling at 1000Hz. Joint angles were determined using the joint coordinate system and moment was determined using inverse dynamics. The variables of interest were peak knee flexion angle, peak internal knee extensor moment (PKEM), knee abduction and external rotation angles at PKEM, and hip adduction and internal rotation angles at PKEM. Independent t-tests compared variables between sedentary and active emerging adult women. Effect sizes (d) were calculated for each variable. **RESULTS:** Knee external rotation angle at PKEM was significantly larger in sedentary compared to active emerging adult women (Table 1). There were no other significant differences between the sedentary and active groups for the remaining variables of interest. **CONCLUSION:** A larger knee external rotation angle at PKEM suggests higher pressure on the lateral patella in the sedentary versus active group. According to the pathomechanical model for PFP, high lateral pressure and associated high cartilage stress is a mechanism for the develop of PFP. Therefore, sedentary women may be more at risk for developing PFP during walking for exercise compared to active women.

Table 1: hip and knee biomechanics during walking in sedentary and active emerging adult women

	Sedentary Mean (SD)	Active Mean (SD)	t	p-value	Effect size (d)
Peak knee flexion angle (°)	15.6 (4.8)	16.1 (5.1)	-0.3	0.78	0.1
Peak internal knee extensor moment (Nm/kg)	0.45 (0.20)	0.60 (0.21)	1.9	0.08	0.8
Knee abduction angle at peak internal knee extensor moment (°)	0.2 (2.4)	-0.2 (3.4)	-0.4	0.71	0.2
Knee external rotation angle at peak internal knee extensor moment (°)	9.1 (3.3)	3.7 (4.5)	3.5	<0.01*	1.4
Hip adduction angle at peak internal knee extensor moment (°)	9.6 (2.5)	8.6 (2.7)	-1.1	0.29	0.4
Hip internal rotation angle at peak internal knee extensor moment (°)	6.7 (4.3)	5.7 (4.6)	-0.6	0.58	0.2

Hallux Valgus And Walking Speed Influence Frontal Plane Net Joint Moments In Older Adults

Carolyn E. Barbee, Harsh H. Buddhadev. *Western Washington University, Bellingham, WA.*
 Email: cbarbee216@gmail.com
 (No relevant relationships reported)

Hallux valgus (HV) is often comorbid with knee osteoarthritis (OA) in older adults. Both these conditions are known to adversely affect walking mechanics, but the biomechanical link between these conditions has not been established. Peak external knee adduction moment is a surrogate measure of knee OA severity and progression. However, this variable is sensitive to changes in walking speed. **PURPOSE:** To examine the effects of HV on peak external knee adduction moment while walking at controlled slow and fast speeds. **METHODS:** Nineteen older adults (65-80 years) with moderate-to-severe HV and 19 healthy older controls completed five walking trials at controlled slow (1.0 m·s⁻¹) and fast (1.3 m·s⁻¹) speeds. Three-dimensional lower extremity marker position and ground

reaction force data were collected at 100 and 1000 Hz, respectively. External knee adduction moment was calculated using an inverse dynamics approach. Peak moments were identified for the more affected leg for the HV group and dominant leg for the control group for each trial. Two-way mixed model ANOVAs were used to examine the effects of group (HV vs. control) and speed (1.0 vs. 1.3 m·s⁻¹) on peak external knee adduction moment.

RESULTS: For peak knee adduction moment a group x speed interaction (p=0.035) was observed. With increase in walking speed external knee adduction moment increased (p<0.001), however, the HV group had twice as much of an increase in net peak knee adduction moment (16.6% greater; 0.53 \pm 0.21 vs. 0.62 \pm 0.25 Nm/kg) as compared to the control group (8.6% greater; 0.51 \pm 0.13 vs. 0.56 \pm 0.13 Nm/kg).

CONCLUSIONS: Older adults with HV show altered knee joint mechanics at faster walking speeds. Knee adduction moment data suggest that older adults with HV may be at a greater risk for developing knee osteoarthritis.

Increased Attentional Focus On Walking By Older Adults Limits Maximum Speed And Dynamic Stability Control

JUTALUK KONGSUK, Christopher HURT. *University of Alabama at Birmingham, BIRMINGHAM, AL.*
 Email: jutalukk@uab.edu
 (No relevant relationships reported)

Older adults with lower balance confidence demonstrate a reduced willingness to experience instability as the task of walking becomes more challenging. The specific reason why is not known. **PURPOSE:** To investigate the extent to which performance of a challenging walking task relates to the attentional requirements of walking. **METHODS:** Fourteen older participants were asked to walk on a treadmill at a range of speeds from 0.4 m/s, increasing 0.2 m/s, up to either 2.0 m/s or a speed they chose to stop. All walking trials included 60 steps. Kinematic data was collected and a measure of margin of stability in the anterior direction at heel strike (MOS_{AP}) was quantified. The timed up and go (TUG) and timed up and go dual task (TUG_{dual}) were performed. An automaticity index (TUG/TUG_{dual} *100) was calculated to evaluate the attentional resources. Individuals were grouped (n=7 in each group) based on whether they could (complete, 70 \pm 2.44 years) or could not (incomplete, 67 \pm 2.43 years) complete all walking trials. Comparisons between groups were made with Independent T-test and Mann-Whitney U test. Correlations were detected with Spearman rank correlation. **RESULTS:** Significant differences were detected in the maximum speeds achieved between groups as well as the range of gait stability (p<0.05). Those that could not complete all speeds had a lower automaticity score compared to other group (p=0.019). The fastest speed attempted was correlated with an average of MOS_{AP} (rho=-0.93, p<0.001) and the automaticity index (rho=0.61, p=0.022). The average of MOS_{AP} and the automatic gait index were significantly correlated (rho=-0.71, p=0.004, Fig 1). **CONCLUSION:** Older adults with lower automaticity of gait appeared to choose to stop limit walking trials before they became dynamically unstable, which may relate with the increased attentional demand required to maintain dynamic stability at higher walking speeds. This should be considered for an assessment to identify stability problems.

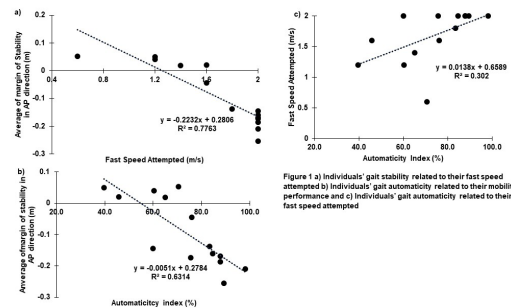

Figure 1 a) Individuals' gait stability related to their fast speed attempted b) Individuals' gait automaticity related to their mobility performance and c) Individuals' gait automaticity related to their fast speed attempted

Walking To A Fractal-like Stimulus Does Not Affect Cardiorespiratory Function

Stuart McCrory¹, Nelson Cortes¹, Lauren Biscardi¹, Navid Ghoddosi¹, Valdir Semedo², Joana Reis², Joao Vaz². ¹George Mason University, Manassas, VA. ²Universidade Europeia, Lisbon, Portugal. ³University of Lisbon, Lisbon, Portugal.
 Email: ncortes@gmu.edu
 (No relevant relationships reported)

Gait complexity decreases with aging. Gait rehabilitation commonly uses step synchronization with external cues; yet, cues do not present variability in its structure. It has been recently suggested that cues should be presented in a fractal-like pattern (i.e., complexity). Yet, the effects of fractal-cueing on physiological outcomes remains poorly understood.

PURPOSE: To investigate the effect of synchronization of visual stimulus with different temporal structures on cardiorespiratory function.
METHODS: 14 male participants (23±4 yrs, 1.8±0.1 m, 70±9 kg) completed four 10-min treadmill walking trials at their preferred walking speed. First, self-paced walking (SPW) condition (no stimulus). Stride time from SPW was used to design individualized stimuli for 3 randomized cue conditions: periodic (PER), fractal (FRC), and random (RND). Detrended fluctuation analysis (DFA) was used to validate the temporal structure of the FRC and RND stimuli. The stimulus was provided via a moving horizontal bar projected on a screen. Heart rate (HR) and oxygen uptake (VO₂) were collected. An accelerometer, placed at the ankle, was used to determine gait events. DFA was used to determine the fractal-scaling exponent from inter-stride intervals (ISI_α). ANOVAs were conducted to assess differences between conditions for all dependent variables (p<0.05).
RESULTS: Descriptive statistics are shown in Table 1. ISI_α was significantly different between conditions (F_{2,44,31.70}=33.76, p<0.0001). FRC and SPW had greater ISI_α than PER and RND.
CONCLUSION: FRC and SPW displayed higher complexity (ISI_α) compared to PER and RND. Compared to SPW, only FRC maintained the complexity of the system. Participants maintained the structure of the stimuli. Notably, FRC appears a viable approach for gait training without altering the cardiorespiratory system, and likely improving gait complexity compared to the PER.

Table 1. Mean ± standard deviation of ISI_α, VO₂, and HR per condition

	FRC	PER	RND	SPW
ISI _α	0.82 ± 0.13	0.48 ± 0.12	0.60 ± 0.12	0.92 ± 0.15
VO ₂ (ml.kg ⁻¹ .min ⁻¹)	13.3 ± 1.7	13.3 ± 1.4	13.2 ± 1.6	13.4 ± 1.5
HR (bpm)	90 ± 11	91 ± 11	94 ± 12	91 ± 13

Gait Metrics For Older Adults Using Different Walking Devices After A Six-week Walking Intervention

Megan Ruppert, Abbie Payne, Lana Prokop, Joshua Guggenheimer. St. Catherine University, St. Paul, MN. (Sponsor: Mark Blegen, FACSM)
 (No relevant relationships reported)

Falls have detrimental effects to older adults' physical and mental wellbeing and can even result in death. The medical system spends billions of dollars on treatment for falls every year. Measuring different aspects of gait, such as gait velocity, can help predict the risk for falling. **PURPOSE:** This study investigated how walking with no device, walking poles, or the gait trainer impacted gait metrics in older adults.
METHODS: Fourteen participants (3 men, 11 women, aged 77.53 ± 7.28 years) were randomized to one of three walking groups: Control (C) (n=4), Walking Poles (WP) (n=5), or Gait Trainer (GT) (n=5). The gait trainer is a new device aimed at preventing age-related gait decline. Assessments were performed at three separate times: prior to the intervention (Pre-test), immediately after the intervention (Post1), and six weeks after Post1 (Post2). Assessments included measurements of gait velocity, cadence, and left and right step lengths for the subjects' normal and fast gait speeds. For the six-week intervention, all participants walked three times per week for 30 minutes in their assigned walking group. **RESULTS:** An ANOVA showed there were no statistically significant differences between the groups at Pre-test for all metrics (p > 0.05). Between group measurements across time were analyzed using linear regression models for all metrics, with an alpha set at p < 0.05. The only statistically significant difference was found for left step length (L SL) for fast gait velocity between the C and WP groups from Pre-test to Post1 (p = 0.03). From Pre-test to Post1, L SL increased in C from 68.4 cm to 73.7 cm and decreased in WP from 73.0 cm to 70.6 cm. There were no statistically significant differences for all other metrics analyzed. **CONCLUSION:** The results from this study found that walking group did not impact gait velocity over time. Gait velocity is determined by step length and cadence, and can be used as a predictor of falls; therefore, walking group did not impact fall risk with the six-week walking intervention, despite the increase in L SL for the C group. The current sample

size was relatively high-functioning and did not show improvement; however, trends indicated a subset of lower functioning participants who have experienced notable age-related gait decline may benefit from the gait trainer.

Lower Body Positive-pressure Walking Reduces Knee Extensor And Plantarflexor Muscle Activity In Obese Women

Rebekah S. Carpenter, Lance M. Bollinger. University of Kentucky, Lexington, KY.
 Email: rebekah.seay@uky.edu
 (No relevant relationships reported)

Muscle contractile activity is a major determinant of oxygen consumption during walking. Obesity increases electromyography (EMG) activity of knee extensors and plantarflexors during walking. **PURPOSE:** To determine how reduced body weight affects lower extremity muscle activity in obese women. **Methods:** Eight obese females (Age: 37.5 ± 8.5y; BMI 36.3 ± 4.0 kg/m²) walked at a self-selected speed (2.3 ± 0.4 mph) on a lower body positive-pressure treadmill (LBPP) during four conditions; control (CON), 10% incline (INC), 25% body weight support (BWS), and BWS+INC. Surface EMG of the vastus lateralis (VL), vastus medialis (VM), semitendinosus (ST), and medial gastrocnemius (MG) were recorded at 1000Hz during the final 30s of each stage. Integrated EMG activity (iEMG), total spectral power (TSP), peak frequency (PF), and median frequency (MF) were calculated over 20 consecutive gait cycles for each subject. **Results:** Compared to CON, INC increased VL iEMG by 38% (p = 0.010) while BWS decreased VL iEMG by 28% (p = 0.037). VL iEMG was lower in BWS+INC compared to INC by 33% (p = 0.002), but was not significantly different from BWS alone (p = 0.133). A significant interaction (p = 0.029) between INC and BWS alone was noted for VM iEMG, but post-test revealed no significant differences among conditions. ST iEMG was not significantly different among conditions. Compared to CON, INC increased MG iEMG (35%, p = 0.015). BWS did not significantly affect MG iEMG compared to CON. MG iEMG was significantly lower in BWS+INC (23%, p < 0.001) compared to INC, but was not significantly different from BWS alone (p = 0.232). Compared to CON, TSP was higher in INC for the VL (232%, p < 0.001) and MG (47%, p < 0.001). BWS significantly decreased TSP compared to CON in MG (35%, p = 0.009), but not VL. TSP was not significantly different between BWS+INC compared to INC or BWS alone. There was a main effect for incline to increase PF of the VL (p = 0.035), but post-tests revealed no significant differences among conditions. MF was not significantly different among conditions in any muscle group. **Conclusion:** Reduced body weight lowers muscle activity of the VL and MG during level and incline walking without significantly affecting motor unit recruitment pools. Reduced VL and MG activity may explain reduced metabolic cost of transport following weight loss interventions.

Effects Of Lower Body Positive-pressure Treadmill Walking On Joint Kinematics And Electromyography In Obese Women.

Lance Bollinger, Rebekah S. Carpenter. University of Kentucky, Lexington, KY.
 Email: lance.bollinger@uky.edu
 (No relevant relationships reported)

Obesity reduces knee flexion and ankle plantarflexion concomitant with prolonged activation of quadriceps and gastrocnemii during walking. **PURPOSE:** To determine how reduced body weight, independent of changes in body segment volume, affects lower extremity joint kinematics and muscle recruitment during walking. **METHODS:** Eight apparently healthy, obese women (Age: 37.3 ± 8.5y; BMI: 36.3 ± 4.1 kg/m²) walked at a self-selected pace on a lower body positive-pressure treadmill (LBPP) under four conditions: 1) control (CON), 2) 10% incline (INC), 3) 25% body weight support (BWS), and 4) BWS + INC. Joint kinematics were measured through bi-axial wireless electrogoniometers and time-synchronized with surface electromyography (EMG) of the vastus lateralis (VL), vastus medialis (VM), semitendinosus (ST), and medial gastrocnemius (MG). The gait cycle was defined by swing, weight acceptance (WA), midstance (MS), and pushoff (PO) according to plantarflexion (PF) and dorsiflexion (DF). Statistical comparisons were made by two-way repeated measures ANOVA. **RESULTS:** Joint kinematics and EMG activity were unchanged throughout swing. At the knee joint, INC increased mean knee flexion during WA (28.3 ± 12.9 v 21.8 ± 14.2°, p < 0.001) and MS (25.3 ± 9.1 v 19.4 ± 12.0°, p = 0.044) compared to CON. BWS + INC reduced mean knee flexion during WA (23.8 ± 13.3, p < 0.001) and MS (21.1 ± 12.4°, p = 0.020) compared to INC. Similarly, mean PF was reduced during INC during WA (10.1 ± 1.7 v 13.6 ± 2.2°, p < 0.001) and MS (4.4 ± 5.3 v 8.0 ± 4.9°, p = 0.008) compared to CON. BWS + INC increased mean PF compared to INC during WA (12.3 ± 1.7°, p = 0.009) and MS (7.0 ± 5.5°, p = 0.006). During PO, both BWS (10.8 ± 4.8°) and BWS + INC (9.8 ± 5.4°) increased mean PF compared to CON (8.1 ± 4.6°) and INC (6.5 ± 6.1°). Compared to CON, INC increased mean VL EMG activity during WA (31.3 ± 10.1 v 17.8 ± 6.0 %MVIC) and MS (19.2 ± 5.2

v 9.5 ± 2.3 %MVIC), which was restored by BWS + INC (19.5 and 12.1 %MVIC). There was a main effect for body weight support to reduce mean MG EMG during MS. **CONCLUSIONS:** Weight loss, independent of changes in body segment volume reduces knee flexion during WA and MS phases of incline walking concomitant with reduced VL EMG activity. Weight loss increases PF throughout stance during incline walking despite reduced MG EMG activity.

Relationships Between Muscle Quality, Maximal And Rapid Torque Characteristics, And Walking Speed In Elderly Females

Ahalee Farrow, Chinonye Agu-Udomba, Ethan Mitchell, Ty Palmer. *Texas Tech University, Lubbock, TX.*
 (No relevant relationships reported)

The link between walking speed, rectus femoris (RF) muscle quality [echo intensity (EI)], and maximal and rapid strength in older adults is not well understood. **PURPOSE:** To examine the relationships between walking speed, RF EI, and maximal and rapid isometric torque characteristics of the leg extensors in elderly females. **METHODS:** Twenty elderly (67 ± 4 yrs.) females underwent one diagnostic ultrasound assessment followed by three isometric maximal voluntary contractions (MVC) of the leg extensors and a 6-min walk test. RF EI was measured on the right leg using a portable B-mode ultrasound imaging device and linear-array probe. Walking speed was determined as the average speed during the 6-min walk test. For each MVC, participants sat in an upright position and were instructed to push "as hard and fast as possible" against a load cell for 3-4 s. Isometric MVC peak torque (PT) was determined as the highest mean 500 ms epoch during the entire 3-4 s MVC plateau. Peak rate of torque development (RTD) was calculated during each MVC as the highest slope value for any 50 ms epoch that occurred over the initial 200 ms of the torque-time curve. Pearson correlation coefficients (r) were used to examine the relationships between walking speed, EI, PT, and RTD. A partial correlation was used to examine the relationship between walking speed and RTD when controlling for EI. **RESULTS:** There were significant relationships between walking speed and RTD ($r = 0.451$; $P = 0.046$) and EI ($r = -0.497$; $P = 0.026$). There was a significant negative relationship between EI and RTD ($r = -0.469$; $P = 0.037$). No relationships were observed between PT and walking speed ($r = 0.394$; $P = 0.085$) or EI ($r = -0.413$; $P = 0.071$). With EI as a control variable, there was no significant relationship between walking speed and RTD ($r = 0.285$; $P = 0.238$). **CONCLUSIONS:** We found a significant positive relationship between walking speed and RTD of the leg extensors in elderly females. Although the reason for this is uncertain, partial correlation analysis suggested that this relationship may be explained by the variance shared (collinearity) between walking speed and RF EI. From a functional standpoint, an age-related decrease in RTD due to its apparent collinearity with RF EI, may significantly impact the quality of life among older adults by impairing their walking speed performance abilities.

Lower Extremity Joint Stiffness And Energy Generation In Gait Transitions

Li Jin¹, Michael Hahn². ¹*San Jose State University, San Jose, CA.*
²*University of Oregon, Eugene, OR.*
 Email: li.jin@sjsu.edu
 (No relevant relationships reported)

Walk-to-run (WRT) or run-to-walk transitions (RWT) occur when walking at a constantly accelerated speed or running at a constantly decelerated speed. Lower extremity joint level kinetic patterns are related to gait transition mechanisms. Little is known about lower extremity joint stiffness, or mechanical work generation in the WRT and RWT processes.

PURPOSE: To identify ankle, knee and hip joint stiffness and mechanical work generation patterns in WRT and RWT processes. **METHODS:** Ten middle age healthy subjects (50.7 ± 6.0 years, 173.4 ± 11.4 cm, 69.7 ± 14.9 kg) participated in treadmill WRT (1.8 m/s - 2.4 m/s) and RWT (2.4 m/s - 1.8 m/s) tests, with acceleration and deceleration set to 0.1 m/s^2 and -0.1 m/s^2 , respectively. Five steps were selected for data analysis: transition step (S0); two steps before transition (S-2, S-1); two steps after transition (S1, S2). Joint stiffness (K_{joint}) was calculated as change in sagittal plane joint moment (ΔM_{joint}) divided by sagittal plane joint angular displacement ($\Delta \theta_{\text{joint}}$) in the braking phase of ground contact ($K_{\text{joint}} = \Delta M_{\text{joint}} / \Delta \theta_{\text{joint}}$). Stance phase joint positive mechanical work (W_{joint}^+) was calculated as the sum of all positive net joint power integrated over time. **RESULTS:** In WRT, K_{ankle} at S2 was higher than S-2 ($p = 0.0004$), S-1 ($p = 0.0007$) and S0 ($p = 0.0001$); K_{hip} at S1 was higher than S-2 ($p = 0.0002$) and S-1 ($p = 0.0001$). In RWT, K_{ankle} at S2 was lower than S-2 ($p = 0.0009$) and S-1 ($p = 0.0006$); K_{hip} at S-1 was higher than S1 ($p = 0.001$) and S2 ($p = 0.0003$). In WRT stance phase, W_{ankle}^+ and W_{knee}^+ were 34% and 60% higher, respectively at S0 compared with S-1; while for W_{hip}^+

there was a significant decrease ($p = 0.0006$) at S0 compared with S-1. In RWT stance phase, W_{ankle}^+ and W_{knee}^+ at S0 were 28% and 42% lower than S-1, respectively; while W_{hip}^+ at S0 was 78% higher than S-1.

CONCLUSIONS: Both WRT and RWT affected K_{ankle} and K_{hip} in the transition step and subsequent steps. Stance phase joint energy generation tended to transfer from proximal to distal during WRT, and vice versa during the RWT process. (Supported by Betty Foster McCue Scholarship.)

Spatiotemporal Gait Asymmetry Distinguishes Fallers And Non-fallers In Below-knee Amputees

Jennifer Ballard, Michael Canlas, Jorge Ceja, Brian D. Street. *California State University Bakersfield, Bakersfield, CA.*
 (No relevant relationships reported)

Introduction: Below-knee-amputees (BKA) are at a higher risk of falling compared to non-amputee controls. Gait patterns have been reported to be an important risk factor of falls: in particular, great disparity in asymmetry of kinematic parameters between lower limbs are observed in BKA. **Purpose:** To investigate differences between spatiotemporal symmetry gait patterns, functional mobility and balance confidence among unilateral BKA fallers and non-fallers. **Method:** Twenty-six unilateral BKA (14 fallers: 47.5 ± 8.6 yrs; $29.5 \pm 4.5 \text{ kg/m}^2$ and 12 non-fallers: 47.5 ± 8.6 yrs; $31.1 \pm 5.5 \text{ kg/m}^2$) completed 5 walking trials, at a self-selected pace, on a 4.3 m GaitRite system. Step length, swing time, and stance time for each limb was collected. Symmetry ratios between limbs were calculated. Self-reported falls within the past 12 months, Timed Up and Go (TUG) Test and the Activity-Specific Balance Confidence (ABC) questionnaire were also collected. Independent t-tests were performed to compare the fallers with the non-fallers. **Results:** The fallers had significantly lower functional mobility (12.1 ± 2.7 v. 8.5 ± 1.1 sec) and reported lower balance confidence (77.4 ± 10.9 v. 87.7 ± 13.7) than the non-fallers ($p < 0.05$). The fallers also had significantly larger step length (1.12 ± 0.05 v. 1.01 ± 0.05), stance time (10.6 ± 0.03 v. 1.02 ± 0.02) and swing time (1.11 ± 0.05 v. 1.04 ± 0.05) asymmetries ($p < 0.05$). **Discussion:** These results suggest that spatiotemporal asymmetry could be useful in distinguishing prospective fallers from non-fallers among BKA. BKA fallers had increased gait asymmetry compared to the non-fallers, which may be attributed to prosthetic alignment, as well as acquired gait changes because of pain, and diminished strength and range of motion. These findings should be used by clinicians to identify BKA at a greater risk of falling, and specific functional and psychological interventions should be considered for these individuals to improve gait asymmetry, functional mobility, and balance confidence.

Calcaneal Eversion Affects Coupled Knee Rotation During Gait

Samuel Pitcairn, MaCalus Hogan, William Anderst. *University of Pittsburgh, Pittsburgh, PA.*
 Email: swpitcairn@pitt.edu
 (No relevant relationships reported)

It has been suggested that ankle motion (specifically, subtalar (ST) and tibiotalar (TT) joints) may contribute to knee pathologies such as patellofemoral pain syndrome. Yet, in-depth understanding of knee and ankle joint coupling remains elusive due to challenges in accurately measuring three dimensional (3D) bone motion *in vivo*. **PURPOSE:** To determine coupled knee and ankle kinematics during the weight-bearing phase of gait in healthy adults. **METHODS:** Dynamic biplane radiography was used to measure coupled kinematics during walking in 12 ankles and knees from six healthy volunteers (ages 18 - 35 yrs.). Synchronized biplane radiographs were collected at 100hz over the entire support phase of gait, from foot-strike through toe-off. Next, CT scans were acquired and subject-specific models of each bone were generated and used to track the 3D bone motion during each trial using a validated technique with sub-millimeter and sub-degree accuracy. Six degrees of freedom ankle and knee kinematics were normalized to percent stance and divided into loading, mid-stance, and push-off phases. The coupled outcome kinematics were 1) ST inversion and knee internal rotation, and 2) TT dorsiflexion and knee flexion. Associations between ankle and knee coupled kinematics were evaluated using Spearman's rho with significance set at $p < 0.05$. **RESULTS:** During midstance, the knee internal rotation always accompanied ST inversion while external rotation accompanied eversion ($R^2 = 0.63$, $p = 0.085$) (Figure 1). During mid-stance TT plantar flexion always occurred with knee extension ($R^2 = 0.12$, $p = 0.71$). **CONCLUSIONS:** In healthy knees, ST inversion/eversion appears to play a role in knee internal rotation during the mid-stance of gait. This finding suggests assessing coupled motion between the knee and ankle may be beneficial for evaluating single joint pathology. This work was supported by NIH Grant: R44HD066831.

Figure 1. Chart showing coupled ST inversion and knee external rotation during mid stance of gait.

Eight Week Gait Modification Intervention To Reduce Knee Adduction Moment: Randomized Controlled Trial: Preliminary Analysis

Bryndan Lindsey, Scott Bruce, Oladipo Eddo, Stuart McCrory, Navid Ghoddosi, Shane Caswell, Nelson Cortes. *George Mason University, Manassas, VA.*
 Email: ncortes@gmu.edu
 (No relevant relationships reported)

Gait modifications (GM) have successfully reduced knee adduction moment (KAM) which is linked with medial compartment knee osteoarthritis (mKOA). Prior studies have largely relied on single-session designs with healthy participants. Experimental designs with mKOA patients are necessary to confirm these findings. **PURPOSE:** Measure the effect of an GM intervention compared to normal walking on KAM in a randomized sample of mKOA patients. **METHODS:** 7 participants with mKOA completed the intervention (61 ± 13 yrs, 1.7 ± 0.1 m, 80 ± 23 kg). After baseline, participants were randomized into GM or control (CTRL) group. The GM group performed trunk lean (TL) - leaning the trunk over the affected limb. During training, the TL group was provided with real-time haptic feedback. No feedback provided for the CTRL group. 8-week training sessions were performed with KAM measured baseline, week 5 (PT1), 8 (PT2), and 1-week post-training (PT3). During posttests, participants performed 5 unprompted trial, and then were prompted to perform TL gait for 5 more (TL group). Two-sample randomization tests were performed to determine if mean change in PKAM and TL angle from baseline to posttests were significantly different between groups (p<0.05). **RESULTS:** TL angle increased and KAM decreased from baseline to posttest when prompted in the GM group compared to CTRL; however, not all differences reached statistical significance (Table 1). **CONCLUSIONS:** Preliminary data suggests that an 8-week intervention is sufficient for mKOA patients to learn and replicate a modified gait strategy when prompted to reduce KAM. Yet, it appears that there is minimal change in TL angle without prompting, suggesting continued training and/or feedback may be necessary for internalization of the modification.

Table 1. Difference in mean change in KAM and TL from baseline to posttest (GM-CTRL). Positive difference in mean KAM change corresponds to “reduction” in KAM from baseline to posttest (closer to zero). *p<0.05

	PT 1		PT 2		PT 3	
	Un-prompted	Prompted	Un-prompted	Prompted	Un-prompted	Prompted
TL Angle (°)	-1.61	3.10	-1.10	2.98*	-2.70	2.48
PKAM Nm/(kg*m)	0.01	0.06	-0.02	0.03	0.07*	0.11*

Persistent Gait Stability Deficits Associated With History Of Concussion

Nicholas Reilly, Jessica Prebor, Jacquelyn Moxey, Eric Schussler. *Old Dominion University, Norfolk, VA.*
 Email: nreil001@odu.edu
 (No relevant relationships reported)

Postural instability during gait is a common symptom following a concussion and is often used as a diagnostic criterion. Specialized equipment has been able to detect impairments in gait patterns and center of pressure (COP) displacement weeks following a concussion. However, difficulty maintaining balance during gait is often not considered when determining whether a concussed individual has made a full recovery unless the impairments are grossly detrimental in nature. **PURPOSE:** To determine if deficits in gait stability seen in concussed individuals persist long after the reception of medical clearance from the initial injury. **METHODS:** Gait parameters were collected using a 20 ft. instrumented pressure-sensitive walkway. Healthy participants reporting a prior history of concussion (n=25) and those reporting no concussion history serving as controls (n=21) were recruited to participate. Individuals with previous history of concussion averaged 7.27 ± 5.73 years since their most recent injury. Participants were instructed to walk in their normal, preferred gait pattern while looking straight ahead. Participants then walked using a tandem gait pattern, walking heel-to-toe in line with each step while looking straight ahead. **RESULTS:** Individuals with prior history of concussion demonstrated significantly greater stride width compared to controls during normal, preferred gait (7.83 cm vs. 10.29 cm, p = 0.09) and tandem gait (0.17 cm vs. 1.63 cm, p = 0.01). Additionally, previously concussed individuals displayed significantly greater single-support COP path length during normal, preferred gait (12.08 cm vs. 12.97 cm, p = 0.06) and significantly greater double-support COP path length during tandem gait (22.71 cm vs. 24.69 cm, p = 0.01). **CONCLUSION:** Individuals that have a sustained one or more concussions demonstrate greater instability in their gait patterns as demonstrated by a wider base of support and greater instability in stance phase during gait years following the initial injury as well as reception of medical clearance. These findings suggest that concussion is associated with long-term impairment in an individual’s ability to maintain postural stability during gait, and that individuals with a prior history of concussion will adopt more conservative gait patterns in order to compensate.

Effect Of Bracing For Scoliosis In Improving Gait Mechanics

Rumit S. Kakar¹, Joshua M. Tome¹, Damon Mar², Kayley LeBlanc², Alex Smashnov², Isador Lieberman², Mark Kayanja², Ram Haddas². ¹*Ithaca College, Ithaca, NY.* ²*Texas Back Institute, Plano, TX.*
 Email: rkakar@ithaca.edu
 Reported Relationships: **R.S. Kakar:** Industry contracted research; Aspen Medical.

Patients with scoliosis demonstrate altered gait due to changes in global postural control strategies caused by pain and the spinal deformity. Bracing has been found to reduce pain and increase trunk support in adult degenerative scoliosis (ADS) patients. However, only anecdotal evidence of their efficacy is available in improving gait and posture control mechanics. **PURPOSE:** Investigate the impact of scoliosis bracing on lower extremity kinematics and effectiveness in gait rehabilitation. **METHODS:** 15 patients with ADS (cobb angle >25°; age:73.9±2.9yr; weight:66.6±16.2kg) were recruited using the adult deformity SRS-Schwab system. Oswestry Disability Index (ODI) scores were recorded and patients performed 3m timed up & go, 6 minute walk tests and over-ground 10m walk trials at a self-selected speed at initial evaluation (pre), 45min post fitting (post45) with Peak™ scoliosis brace and after 8 weeks of bracing (post8w). Gait variables were calculated for 5 walking trials and compared between the 3 time points (pre, post45 and post8w) using RM-MANOVA (p< .05). **RESULTS:** Patients walked faster on 3m timed test (pre: 12.5s; post8w: 10.0s) and covered greater distances in the 6 min walk test (p= .01; 61.2m). For kinematic variables, significant differences were observed for swing time of left leg (p =.013; pre:0.40s; post45:0.42s; post8w:0.39s), step length on right (p=.019; pre:0.52m; post45:0.57m; post8w:0.56m), right ankle peak dorsiflexion (p =.049; pre:8.7°; post45:7.9°; post8w:11.7°), both knee peak flexion and extension angles (p <.001- .048), and right hip (p =.002; pre:37.2°; post45:39.2°; post8w:31.6°) and knee ROM (p =.018; pre:29.8° ; post45:31.6°; post8w:37.7°). ODI pain scores (p=.06) showed tendency for statistical significance. **CONCLUSIONS:** Patients with scoliosis demonstrated few immediate and long-term benefits for improving pain and altered gait mechanics. Faster walking speeds, greater walking distances, longer step lengths and greater ROM as observed are indicators of improved gait and dynamic balance. Bracing has immediate effects on improving ambulation and for any neuromuscular adaptation, brace might need to be worn for at least 8 weeks.

The Effect Of Race On Gait Biomechanics In Young Adults: A Pilot Study

Judy Foxworth, Christopher Wendt. *Winston Salem State University, Winston-Salem, NC.* (Sponsor: Audrey Lynn Millar, FACSM)

(No relevant relationships reported)

Age, obesity and altered knee biomechanics are known risk factors for developing knee osteoarthritis (OA) in the elderly. Recently racial differences in gait biomechanics have been associated with progression of knee OA in the elderly. It is unknown if these racial differences in gait biomechanics exists in healthy young adults. **Purpose:** The purpose of this study was to determine if there are biomechanical gait differences between young African-American (AA) and Caucasian (C) adults. **Methods:** 20 young adults between the ages 18-30 volunteered for this study. Participants completed a self-report version of the Knee Injury and Osteoarthritis Outcome Score (KOOS). A 10-camera motion capture system and 2 force plates embedded in a walkway were used to collect kinematic and kinetic data while participants completed 5 walking trials at a self-selected pace. 3D knee torques were calculated using inverse dynamic analyses. Gait velocity was collected as participants walked across a 14 foot GaitRite® instrumented carpet at both a self-selected (SS) and fast (F) pace. Outcome variables were internal knee adductor (KAD) and knee abductor (KAB) torque and gait velocity (SS, F). Data analysis was conducted using independent sample (AA vs C) t-test for all outcome measures with the alpha level set at $p < .05$. **RESULTS:** Nine AA (5 females; 4 male) and eleven C (4 females; 7 males) young adults participated in this study. No significant differences were found between the groups for BMI (AA = 28.6 ± 6.6 ; C = 25.5 ± 4.9), age (AA = 25.76 ± 1.5 years; C = 26.1 ± 2.5), or KOOS Global scores (AA = 90.1 ± 15.24 ; C = 94.5 ± 6.2). There were no significant differences found in any of the studied outcome variables.

Outcome Variable	African American	Caucasian
Left KAD (%BW*Ht)	$0.65 \pm .4$	$0.64 \pm .5$
Right KAD (%BW*Ht)	$0.63 \pm .5$	$0.55 \pm .3$
Left KAB (%BW*Ht)	$2.57 \pm .5$	$2.33 \pm .8$
Right KAB (%BW*Ht)	$2.74 \pm .2$	$2.9 \pm .8$
SS gait velocity (m/sec)	$1.20 \pm .07$	$1.28 \pm .07$
F gait velocity (m/sec)	$1.87 \pm .07$	$2.0 \pm .25$

All torques listed are internal torques. **CONCLUSION:** These findings do not support the hypothesis that there are racial differences in gait velocity or knee torques during gait between African American and Caucasian healthy young adults. The generalizability of this study is limited by the small sample size.

The Independent Effects And Interaction Of Gravitational And Inertial Forces On Gait Transition Speed.

Nathan G. Frakes, Justus D. Ortega, Courtney A. Perry. *Humboldt State University, Arcata, CA.*
 Email: Nathanfrks@gmail.com

(No relevant relationships reported)

Prior research suggests the relation between gravitational and inertial forces plays an important role in the determination of the preferred transition speed (PTS) for both walk to run transitions (WRT) and run to walk transitions (RWT), and that humans prefer to transition gait when the ratio of inertial force (IF) to gravitational force (GF) (i.e. Froude #) is ~ 0.5 .

Purpose: In this study, we investigated the effect of gravitational and inertial forces on PTS and Froude # for both WRT and RWT. We hypothesized that decreasing gravitational force (-GF) would decrease PTS and increase the Froude # at PTS, but that increases in inertial forces (+IF) or increases in both gravitational force and inertial forces (+GF+IF) would not affect PTS.

Methods: Twelve healthy adults (9 M, 3 F) performed WRT and RWT trials on a motorized treadmill across seven combinations of altered body weight (BW) and body mass (BM). Subjects performed the PTS at 1.0BM/1.0BW, 0.70 and 0.85 BW /1.0 BM (-GF), 1.15 and 1.30 BM / 1.0 BW (+IF), and 1.15 and 1.30 of both BW and BM (+GF+IF). For each condition, we determined PTS (m/s and Froude #) by increasing speed (WRT) or decreasing speed (RWT) 0.09 m/s every 30 seconds through two speeds beyond the PTS.

Results: -GF decreased the PTS of WRT ($p=.02$). At 0.70 BW, the PTS was 93% (1.83 m/s) that of the control (1.97 m/s). Neither +IF ($p=.156$) nor +GF+IF ($p=.149$) affected the PTS of WRT. -GF increased the Froude # at WRT ($p=.01$). At 0.70 BW, PTS Froude # was 120% (Fr=.53) of the control (Fr=.44). +IF also increased the WRT Froude # ($p<.001$). At 1.30 BM, the Froude # was 132% (Fr=.58) of the control. +GF+IF did not affect the Froude # at WRT ($p=.135$). There was no change in PTS

for RWT due to -GF ($p=.263$), +IF ($p=.658$) or +GF+IF ($p=.202$). Yet, -GF increased the Froude # of RWT ($p<.001$). At 0.70 BW, RWT Froude # was 131% (Fr=.55) of the control (Fr=.42). Moreover, +IF increased RWT Froude # ($p<.001$). At 1.30 BM, RWT Froude # was 140% (Fr=.59) of the control. +GF+IF did not affect the Froude # of RWT ($p=.426$).

Conclusion: This study suggests WRT speed and Froude # are influenced by changes in gravitational forces but are unaffected by changes in inertial forces or proportional changes in both gravitational and inertial forces. In contrast, the relation between gravitational and inertial forces did not appear to influence RWT speed but did affect the RWT Froude #.

2670 Board #131 May 29 9:30 AM - 11:00 AM
Restriction In Hip Internal Rotation During Stance Phase In An Early Stage Of Hip Osteoarthritis

Masanori Takemura¹, Kenichi Ichihashi¹, Mitsuharu Kaya², Hayato Yamamoto³, Kouji Kurita⁴, Arijit Banerjee⁵, Junzo Tsujita⁶. ¹Ichihashi clinic, Kobe, Japan. ²Hyogo University of Health Sciences, Kobe, Japan. ³Doshisha University, Kyoto, Japan. ⁴Physical Conditioning Production, Osaka, Japan. ⁵Amagasaki-city Board of Education, Amagasaki, Japan. ⁶Institute of Health & Sports Medical Science, Nishinomiya, Japan.

(No relevant relationships reported)

Most studies of gait analysis in hip osteoarthritis (OA) have involved patients with end-stage hip osteoarthritis or after total hip replacement. However, there have been few studies of patients with early stage of hip OA is few investigation. **PURPOSE:** The purpose of this study was to analyse of gait pattern in the hip joint during stance phase, in patients with early stage of hip OA.

METHODS: Data of gait analysis was obtained from medical records of patients. Patients with early stages of hip OA (without acetabular dysplasia [sharp angle 41.9 ± 4.59 deg.], $n=22$, female, age: 55.4 ± 7.962 [44-70] yrs, height: 156.7 ± 5.14 cm, weight: 51.5 ± 6.75 kg [Hip OA]) and patients with traumatic temporomandibular disorder after a road traffic accident without lower extremity and lower back disorder ($n=20$, female, age: 51.9 ± 7.95 [40-66] yrs, height: 160.0 ± 5.86 cm, weight: 54.0 ± 8.76 kg [C]) between 2014 and 2019. Two-way ANOVA was used for statistical analysis between group [Hip OA-C] and within subject [side].

RESULTS: Results (mean \pm SD) of range (degree) of hip extension to flexion during gait cycle were C 48.0 ± 6.63 and Hip OA 45.3 ± 8.29 ($p > .05$). Range of hip adduction of Hip OA was significantly smaller than C ($F = 4.72$, $p < .05$, $ES f = 0.438$). Results of range of hip adduction during early stance phase were C 9.1 ± 3.44 and Hip OA 7.2 ± 2.44 . Range of hip adduction of Hip OA was significantly smaller than C ($F = 4.72$, $p < .05$, $ES f = 0.438$). Results of range of hip internal rotation during early stance phase were small side C 9.7 ± 3.75 , large side C 11.6 ± 3.71 , affected side Hip OA 7.50 ± 3.84 and unaffected side Hip OA 11.2 ± 3.62 . Results of range of hip internal rotation were observed interaction ($F=8.90$, $p<.01$, $ES f=0.472$). Unaffected side Hip OA was significantly smaller than unaffected side ($F = 80.39$, $p<.001$, $ES f = 1.418$) and small side of C ($F = 3.26$, adjusted $p < .15$, $ES f = 0.285$).

CONCLUSIONS: In patients with early stage of hip OA, hip extension during gait wasn't restricted, but hip adduction and hip internal rotation during early stance phase of gait were restricted. This hip joint restriction may be influenced by degeneration of ligamentum teres femoris which carries blood supply of femur head. Rotation restriction during stance phase by weight-bearing in early phase of hip OA occurs before hip joint extension restriction.

Bilateral Imbalance Of Distal Electromyography Is Not Acutely Altered By Exercise Mode In Chronic Stroke

Nicholas J. Siekirk¹, Bradley Kendall², Victoria Pardo³, Qin Lai³, Sujay Galen⁴, Trevor McCready⁵, Samantha Atty⁶, Zachary Atwood³, Jordan Brown¹, Sam Wilson¹, Jessica Mutchler¹, Tamara Hew-Butler, FACSM³. ¹Georgia Southern University, Statesboro, GA. ²Taylor University, Upland, IN. ³Wayne State University, Detroit, MI. ⁴Georgia State University, Atlanta, GA. ⁵Central Michigan University, Mount Pleasant, MI. ⁶University of Southern California, Los Angeles, CA. (Sponsor: Tamara Hew-Butler DPM, PhD, FACSM, FACSM)

Email: nsiekirk@georgiasouthern.edu

(No relevant relationships reported)

Exercise interventions that approximate the stepping motion are thought to be useful in gait recovery after stroke. However, it remains unknown if hemiparetic asymmetry remains consistent between common exercise modes. **PURPOSE:** Therefore, our primary purpose was to examine contralateral mEMG (i.e., affected leg vs. non-affected leg) of chronic stroke survivors (SC) (10 \pm 5 years post) and age plus sex-matched control (HC) on the NuStep Cross Trainer (NS) and Treadmill (TM).

METHODS: In order to determine self-selected (SS) cadence, each participant performed a 10 minute (min) pretest on the NS and TM at an RPE between 12 and 16. After returning to resting heart rate and blood pressure, participants performed a 5-minute exercise bout on the NS and TM at the SS. The exercise order was randomized. mEMG values were recorded from the rectus femoris (RF), vastus medialis oblique (VMO), semitendinosus (ST), tibialis anterior (TA), medial gastrocnemius (MG) and soleus (SOL) bilaterally. mEMG amplitudes (uV) were converted to a percentage of isometric maximum voluntary contraction (%mVc). Five separate 2 x 2 repeated measures ANOVA were used to examine the effect of limb (i.e., affected vs. non-affected) and exercise mode (i.e., TM vs. NS) on mEMG. Post-hoc data are presented as mean and 95% confidence interval. **Summary of RESULTS:** SC (n = 15) and HC (n = 19) did not differ in age or BMI; $p > .05$. The repeated measures ANOVA found no interaction or main effects for the proximal musculature (i.e., RF, VMO, ST); $p > .05$. However, main effects for limb were detected for the distal musculature (i.e., MG, SOL, and TA); $p < .05$. The non-affected MG produced higher mEMG ($M = 105.08\%mVc$; $CI = 39.52\% - 170.64\%$) than the affected side ($M = 48.92\%mVc$; $CI = 33.58\% - 64.26\%$); $p = .047$. The non-affected SOL produced higher mEMG ($M = 121.65\%mVc$; $CI = 20.68\% - 222.61\%$) than the affected side ($M = 47.96\%mVc$; $CI = 15.49\% - 80.43\%$); $p = .042$. Post-hoc analysis revealed the non-affected TA produced higher mEMG ($M = 33.29\%mVc$; $CI = 21.76\% - 44.81\%$) than the affected side ($M = 18.79\%mVc$; $CI = 14.30\% - 23.29\%$); $p < .001$. **CONCLUSION:** Distal musculature demonstrated higher mEMG in the non-affected limb despite exercise mode. This gives preliminary evidence supporting the use of the NS to elicit mEMG values similar to the TM in the proximal leg musculature.

2672 Board #133 May 29 10:30 AM - 12:00 PM Changes In Dual-task Gait Speed Following A 10-week Golf Program In Older Adults

Jared Moore¹, Kiran Kanwar¹, Karen Lee¹, Roger Hawkes², George Salem, FACSM¹. ¹University of Southern California, Los Angeles, CA. ²University College London, London, United Kingdom. (Sponsor: George Salem, FACSM)
Email: jaredmoo@usc.edu
(No relevant relationships reported)

PURPOSE: To examine the change in dual-tasking ability during gait in response to a golf exercise program in healthy, older adults. **BACKGROUND:** The ability of older adults to perform dual-tasking during gait has been studied as a predictor of fall risk. Therefore, it is important to investigate exercise programs that not only improve fitness and balance in older adults, but also enhance the ability to dual-task. **METHODS:** Fifteen healthy, older adults without previous golf experience were enrolled in a golf program with fitness testing before and after the intervention. One participant had to drop out of the study due to a work-related injury at week 8. Dual-task performance was measured using a fast-gait task while counting backwards by threes on a Protokinetics™ walking mat. Cognitive cost was determined by normalizing the dual-task responses to a seated counting task. Paired t tests were run to determine significance. Results are presented as mean±SD. Cohen's d effect sizes were calculated and reported as small=0.2, medium=0.5, and large=0.8. **RESULTS:** Gait speed during the dual-task was significantly increased following the golf program with a large effect size ($1.75 \pm 0.19m/s$ to $1.91 \pm 0.22m/s$; $p=0.007$; $d=0.85$). This increase in gait speed coincided with increases in both average stride length (2.3%; $p=0.061$; $d=0.55$) and average cadence (5.8%; $p=0.059$; $d=0.55$). Cognitive dual cost did not change between pre and post testing but trended towards improving (40.94%; $p=0.207$; $d=0.35$). **CONCLUSION:** Golf is a unique, multimodal activity that has a beneficial impact on fitness in healthy, older adults. This study demonstrated that a golf program can improve the ability to perform dual tasking. Participants were able to increase their gait speed without compromising the amount of numbers they could recite correctly. The participants trended towards an improved correct response rate following the program as shown by the improvement in cognitive dual cost. Golf should be encouraged as a physical activity program for older adults. Supported by R&A Grant GHA0012017.

2673 Board #134 May 29 10:30 AM - 12:00 PM Feasibility And Adherence Of A Novel Golf Training Intervention For Healthy Older Adults

Guanrong Cai¹, Jared Moore¹, Kiran Kanwar¹, Karen Lee¹, Roger Hawkes², George Salem, FACSM¹. ¹University of Southern California, Los Angeles, CA. ²University College London, London, United Kingdom. (Sponsor: George Salem, FACSM)
Email: guanrong@usc.edu
(No relevant relationships reported)

Golf is a multimodal physical activity that can potentially be utilized as a health intervention for diverse populations. Golf includes aerobic, power, balance, and cognitive training, yet is overlooked as a therapeutic program due to notions of cost and feasibility. Adherence rate is also a key measure of success in intervention studies. No previous evidence has demonstrated the adherence and feasibility of a golf-based training program in older adults whom did not play golf. **PURPOSE:** This study will report on the adherence and feasibility of a novel 10-week golf training program for healthy older adults. **METHODS:** Fifteen healthy, older adults enrolled and fourteen completed a 10-week golf training program with physical and cognitive testing before and after the program. The golf program consisted of warm up exercises, driving range practice, and golf play twice per week for 90 minutes, under the supervision of a PGA instructor. Functional, fitness, and cognitive measurements were taken in pre- and post-testing. The attendance rate, program-related adverse events, and cost related to the program were collected to determine the adherence and feasibility of the program. **RESULTS:** Participants completed 283/300 (94%) scheduled training sessions. There were no adverse events or drop-outs related to the intervention. Fourteen of fifteen participants completed pre- and post- testing, with one participant leaving the study at week 8 due to a work-related injury. Improvements were found in strength, functional, balance, and cognitive measures. The individual subject investment for the 10-week golf program was \$1,100, which included clubs, hand-cart, range and green fees, lessons, and necessary accessories. The average cost of playing 9 holes on 7 Los Angeles city golf courses is \$8.88 (±2.18) for older adults. There are 29 courses with green fees for 18 holes under \$20 (booked on golfnow.com and open access to public) within a 30-mile radius of downtown Los Angeles. **CONCLUSION:** The nature of golf allows it to be incorporated as a multimodal training intervention that is beneficial for older adults. The cost data demonstrate that golf can be financially feasible for older adults living in the Los Angeles region to participate regularly. Golf should be utilized when designing health and fitness interventions for older adults.

2674 Board #135 May 29 10:30 AM - 12:00 PM Short-term Multicomponent Exercise: Effective For Addressing Major Variables That Influence Fall Risk In Older Adults

Brett D. Bruininks, Derick Hansen, Lauren Wikstrom, J. Adam Korak. University of St. Thomas, St. Paul, MN.
Email: brui8983@stthomas.edu
(No relevant relationships reported)

Falls are commonly linked to gait and balance inconsistencies, influenced by a combination of variables including muscle strength and power. For years, short-term higher intensity multi-component dynamic training methods have been used to improve athletic performance in younger populations by significantly affecting variables including muscular strength and force, gait, and balance. Currently, there are a number of fall prevention programs. However, questions specifically surrounding mode and duration of these fall prevention programs still exist. **PURPOSE:** To determine if a short-term, 8-week multi-component dynamic resistance-training program is effective in eliciting positive changes in factors that directly influence fall risk in older adults. **METHODS:** Forty men and women (ages 55-90 yrs.; mean = 69.5) performed 8-weeks of multi-component dynamic training (3x/week; 45-minutes per session) consisting of skill appropriate agility and change of direction training, specific lower body strength exercises, and both stationary and dynamic balance training. Muscle performance was measured pre/post using a 10RM bilateral leg extension and a standardized sit-to-stand test. Repetition-by-repetition force (N) was assessed using a calibrated force plate during the sit-to-stand test. Balance, gait, and speed were measured via standardized balance and walking tests. Changes in lean and fat masses were obtained via dual energy X-ray absorptiometry (DXA). Pre/post mean differences were analyzed using Paired T-tests. **RESULTS:** Training elicited positive outcomes in all muscle performance variables. Sit-to-stand efficiency increased (+53.9%; $p<0.001$) and repetition-by-repetition mean force improved +6.0% ($p<0.05$) during the same test. Significant increases in mean 10RM bilateral leg extension (+8.6kg; +28.0%; $p<0.001$), and positive balance changes were also observed (11.5%; $p<0.01$). Walking time decreased in all participants (-30.1%; $p<0.001$). **CONCLUSION:** Shorter, higher intensity dynamic exercise can be a safe and effective way to improve muscle performance, gait speed, and balance in older adults at risk for falling.

2675 Board #136 May 29 10:30 AM - 12:00 PM

Associations Between Muscular Strength And Digestive System Disorders In Older Adults

Bong Kil Song, Angelique G. Brellenthin, Duck-chul Lee, FACSM. *Physical activity epidemiology lab, ames, IA.* (Sponsor: Duck-chul Lee, FACSM)
Email: bksong@iastate.edu

(No relevant relationships reported)

PURPOSE: To examine the associations of handgrip strength (HGS) with prevalence of digestive system disorders (DSD) in older adults.

METHODS: This cross-sectional study included 511 older adults (57% women; mean age 72 years old) who were without heart attack, stroke, or cancer in the past 5 years. HGS was calculated as the sum of the maximal contractions from both hands. Participants were categorized into sex-specific tertiles (thirds) of HGS. DSD cases were identified via self-administered medical history questionnaire. The DSD were further categorized into disorders of the upper tracts (gastroesophageal reflux disease, ulcers), intestines (irritable bowel syndrome, inflammatory bowel disease, diverticulitis), or accessory organs (gallbladder, liver, pancreas). Logistic regression was used to calculate the odds ratios (ORs) and 95% confidence intervals (CI) of DSD among HGS thirds while adjusting for sex, age, smoking, heavy alcohol consumption, diet quality, cardiorespiratory fitness, and body mass index (BMI). **RESULTS:** There were 192 DSD cases. Compared with the lower third of HGS (least strong), the ORs (95% CIs) of having DSD were 0.58 (0.37-0.92) and 0.50 (0.31-0.81) among those in the middle and upper (strongest) thirds, respectively, after adjusting for the possible confounders. Similar trends were observed in the DSD of the upper tracts, intestines, and accessory organs. In a joint analysis of HGS and BMI (another strong risk factor of DSD), participants were dichotomized into weak (lower third) or strong (middle and upper thirds) and normal weight (<25.0 kg/m²), overweight (25.0-29.9 kg/m²), or obese (≥30.0 kg/m²) based on BMI. Compared with the weak-obese group, ORs (95% CIs) were 0.60 (0.28-1.27), 0.27 (0.11-0.65), 0.43 (0.21-0.88), 0.41 (0.20-0.83) and 0.13 (0.06-0.30) for the weak-overweight, weak-normal weight, strong-obese, strong-overweight, and strong-normal, respectively, after adjusting for the possible confounders. **CONCLUSIONS:** HGS was inversely associated with DSD in older adults. In addition, higher HGS appears to attenuate the increased prevalence of DSD in overweight and obese participants. Prospective studies are warranted.

2676 Board #137 May 29 10:30 AM - 12:00 PM

Effects Of Undulating Vs. Linear Periodization On Body Composition In Untrained Older Adults

Salvador Vargas-Molina¹, Manuel García-Sillero¹, Ramón Romance², Ignacio Medina¹, Diego A. Bonilla³, Brad J. Schoenfeld⁴, Jorge L. Petro⁵, Richard B. Kreider, FACSM⁶, Javier Benítez-Porres². ¹EAD-University of Wales Trinity Saint David, Málaga, Spain. ²University of Málaga, Málaga, Spain. ³DBSS Research Division, Bogotá, Colombia. ⁴CUNY Lehman College, New York, NY. ⁵Universidad de Córdoba, Montería, Colombia. ⁶Texas A&M University, College Station, TX. (Sponsor: Richard B. Kreider, FACSM)
Email: salvadorvargasmolina@gmail.com
(No relevant relationships reported)

The effects of undulating periodization (UP) on body composition and strength during a resistance training (RT) program have been investigated in both sedentary and trained individuals; however, research on the topic is limited in an elderly population. **PURPOSE:** The aim of this study was to evaluate the effect of an UP-RT program on body composition in older adults. **METHODS:** Seventeen ($n=9$, men; $n=8$, women) untrained elderly individuals (64.2±2.0 years, 72.2±10.8 kg; 164.8±7.6 cm; 25.6±2.6 kg·m⁻²) with no previous RT experience were randomly assigned to either a linear training ($n=8$, LT) or UP ($n=9$) program. After 3 weeks of familiarization, all participants performed three weekly RT bouts over an 8-week study period. Body composition was assessed via dual energy X-ray absorptiometry. Statistical comparison (pre-test vs post-test) was performed with the paired t test or Wilcoxon (depending on the normality of the data), and a repeated measures ANOVA was employed to determine interactions (Time=pre-test vs test; Group=LT vs UP and Time x Group). Effect size (ES) was calculated with Hedges g; the normality and homogeneity of the data were checked with the Shapiro-Wilk and Levene tests, respectively. **RESULTS:** The results are reported in the order of LT and UP, respectively. No significant changes were found for the study variables: BM ($\Delta=-0.3\pm 1.0$ kg; $P=0.374$; ES=-0.05 and $\Delta=0.6\pm 1.0$ kg; $P=0.101$; ES=0.06), FM ($\Delta=-0.6\pm 1.3$ kg; $P=0.212$; ES=-0.24 and $\Delta=-0.7\pm 2.3$ kg; $P=0.389$; ES=-0.17) and FFM ($\Delta=0.3\pm 1.8$ kg; $P=0.679$; ES=0.04 and $\Delta=1.3\pm 2.4$ kg; $P=0.145$; ES=0.17). No statistical differences were found between training protocols.

CONCLUSIONS: Although body composition variables did not change significantly over the study period, the slight improvements observed conceivably can contribute to the health of these older adults; this hypothesis is corroborated by parallel studies that

we have carried out in this population. Given previous data showing exercise-induced FFM gains in the elderly, it can be speculated that lack of significant findings may be the result of suboptimal caloric and/or protein consumption.

2677 Board #138 May 29 10:30 AM - 12:00 PM

Associations Of Cardiorespiratory Fitness And Muscular Strength With Cognition In Older Adults

Angelique G. Brellenthin, Duck-chul Lee, FACSM. *Iowa State University, Ames, IA.* (Sponsor: DC Lee, FACSM)

(No relevant relationships reported)

Purpose: Cardiorespiratory fitness (CRF) has been associated with better cognitive function. However, considerably less is known about relationship between muscular strength (MS), independent of and combined with CRF, on cognitive function in older adults.

Methods: This cross sectional study included 499 older adults (56% women; mean age 72 years old). CRF and MS were assessed with the 400-meter walking test (minutes) and handgrip strength (kg), respectively. Poor cognitive function was defined the slowest 20% of congruent (CRT) and incongruent (IRT) reaction times from the Stroop Color-Word Task. Logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (CIs) for CRT and IRT among sex-specific tertiles (thirds) of CRF and MS. Participants were further categorized as Fit (middle/upper CRF) or Unfit (lower CRF) and Strong (middle/upper MS) or Weak (lower MS) for a joint analysis. Covariates included sex, age, body mass index, smoking, heavy alcohol intake, depression, daily steps, diabetes, hypertension, hypercholesterolemia, and CRF or MS in respective analyses.

Results: Compared with the lower third of CRF, the middle and upper thirds had 0.47 (0.26-0.86) and 0.42 (0.21-0.84) reduced odds of poor CRT, respectively, and 0.44 (0.24-0.80) and 0.48 (0.24-0.97) reduced odds of poor IRT, respectively, after adjusting for all covariates including MS. Compared with the lower third of MS, the middle and upper thirds had 0.54 (0.31-0.94) and 0.51 (0.28-0.94) reduced odds of poor CRT, respectively, after adjusting for all covariates including CRF. No associations were found between MS and poor IRT. In a joint analysis, compared with the Weak & Unfit group, the odds of poor CRT were 0.48 (0.23-1.00), 0.37 (0.17-0.79), and 0.25 (0.13-0.49) for the Strong & Unfit, Weak & Fit, and Strong & Fit groups, respectively. Compared with the Weak & Unfit group, the odds of poor IRT were 0.75 (0.37-1.55), 0.31 (0.13-0.71), and 0.39 (0.20-0.75) for the Strong & Unfit, Weak & Fit, and Strong & Fit groups, respectively.

Conclusion: These results indicate that both CRF and MS are independently associated with faster processing speed (i.e., CRTs), but that CRF may be more strongly associated with tasks requiring executive function (i.e., selective attention in the IRTs) than MS.

2678 Board #139 May 29 10:30 AM - 12:00 PM

Applying Decision Tree Technique To Predict Fall Risks Classified By Functional Fitness In Older Adults

muncheong choi¹, Hong-Sun Song², Suhong Kim¹, Joong-Sun Eo¹, Miyoung Lee¹. ¹kookmin university, seoul, Korea, Republic of. ²Korea Institute of Sport Science, seoul, Korea, Republic of. Email: bdforever@hanmail.net

(No relevant relationships reported)

Purpose: To examine an accuracy of the fall risk classification predicted by senior functional fitness tests and health conditions in Korean older adults utilizing a decision tree technique, which is a machine learning algorithm

Methods: A total of 732 older adults (Males 45.9%, age: 73.51±6.20yrs, BMI: 24.07) participated in Korea Survey of National Physical Fitness (KSNPF). All participants performed the senior physical fitness test (SPFT) including body composition (FAT%), 6min walk, hand grip(HG), timed up-and-go (TUG), and chair sit-and-stand. Also, demographic variables (income, employment, etc.) and health markers were measured, which were including blood pressure & waist and hip circumferences as well as physical activity levels and health conditions (disease, medication, and fall experiences). All utilized measures were validated for the Korean elderly in 2014. To determine a classifier of a fall risk and to set cut-off scores of the fall risk classification, a decision tree technique with CHAID algorithm (Kass, 1980) was applied. To examine the accuracy of the fall risk classification predicted by selected variables, 80% of participants were randomly selected to derive the equation for a training group (GR) and the others were assigned for a cross-validation GR (20% for testing). **Results:** Only TUG and HG were significant classifiers with 87.6% of accuracy in the testing GR and 86.6% of precision in the cross-validation GR, respectively. The cut-off score of TUG was 7.13sec. (chi-square=21.22, p<.001), in which 21.1% of participants were classified into the fall risk GR. Within the TUG GR (<7.13sec.), the cut-off score of HG were set as 23.6kg (chi-square=14.87, p<.001), and 52.8% (<23.6kg) was classified into the fall risk GR. **Conclusions:** Among SPFT tests and health related variables, TUG and HG were relatively important to predict the fall risk for the healthy elderly in Korea. Coordination and strength exercise are critical for fall prevention in older adults. *Corresponding author (mylee@kookmin.ac.kr)

Effect Of TaiChi Sward On Function-related Outcomes In Older Adults

Yaofeng Liu. *Hubei Minzu University, Enshi, China.*
 (No relevant relationships reported)

PURPOSE: The purpose of this present study was to examine the effect of Tai Chi sward (TS) on physical function in Chinese older adults.

METHODS: 160 Chinese older adults were randomly assigned into either an experimental group experiencing four 90-minute TS sessions weekly for seven consecutive weeks or a control group. At baseline and 7 weeks later, all participants were asked to perform physical functional tests for both lower and upper limbs. The test included leg strength, dynamic balance, the Back Scratch Test, One leg Stand Test, the Arm Curl Test, the maximum isometric strength of the hand and forearm muscles, the Spiral Drawing Test, and Moberg Pickup Test.

RESULTS: The finding showed that TS group experienced positive changes on Handgrip Strength Test (17.40 to 22.45), Arm Curl-Up Test (19.25 to 24.28), Back Scratch Test (15.36 to 19.56), Timed Up and Go Test (13.51 to 12.24), and One leg Stand Test (15.65 to 23.37).

CONCLUSIONS: The findings indicated that a short-term and intensive TS training program does not only improve low limb-related physical function such as dynamic balance and leg strength, but also strengthen upper limb-related physical function (e.g., arm and forearm strength, shoulder mobility, fine motor control, handgrip strength, and fine motor function). Health professionals could take into account TS exercise as an alternative method to help maintain or alleviate the inevitable age-related physical function degeneration in healthy older adults.

 (No relevant relationships reported)

The hand-grip strength test (HST) is one of the most utilized tests to measure muscle strength in older adults. It has been used to assess sarcopenia and fragility in older adults' populations. **PURPOSE:** The aim of this study is to compare HST data from active older adults engaged in a physical activity promotion program in Spain with normative values of the general population in the same age ranges in Colombia (Ramírez-Vélez et al., 2019) and South Korea (Yoo et al., 2017). **METHODS:** 1,862 older adults aged ≥ 60 years old who participated in a physical activity promotion program were evaluated with the HST measured with a dynamometer. For the comparison with the other international cohorts [Colombian $N_c=5237$ (≥ 60) and South Korean $N_{sk}=935$ and 147 (≥ 65 and ≥ 80 , respectively)], we divided the study by gender (W = women and M = men) and by age ranges ($\geq 60=1$, $\geq 65=2$ $\geq 80=3$). From our 1,862 sample, we included all of them in 1 (W=1632 and M=230), 1840 in 2 (W=1608, M=232) and 807 in 3 (W=695, M=112). **RESULTS:** Sample (n) and population (N_{sk} and N_c) averages HST values (kg) were obtained in the three age groups (1, 2, and 3). The means were 1 = n (W:20.3; M:34.2) and N (W:16.7; M:26.7); 2 = n (W:19.8; M:33.1) and N (W:20.5; M:33.6); and 3 = n (W:18.9; M:31.1) and N (W:16.7; M:26.9). The Cohen's *d* effect size as the standardized mean difference between n and N using the standard deviation of N due to the large sample size was calculated. The results were as follows: 1 = (W:0.63; M:0.88); 2 = (W:-0.14; M:-0.07); and 3 = (W:0.48; M:0.70). **CONCLUSION:** The comparison shows that our sample data obtained higher values in HST by gender as well as by age, with moderate (0.63) to high (0.88) effect sizes when compared to Colombian data over 60 years old. The comparison with South Korean age groups shows that there are no differences when comparing our sample data with over 65 years data however the effect sizes are moderate when comparing older age groups (≥ 80). These findings suggest that physical activity could be an optimal therapeutic treatment against the muscle lost assessed with the HST even in older adults aged ≥ 80 years old.

Changing Physical Activity In Older Adults With Heart Failure By Increasing Exercise Or Reducing Sitting

Jennifer M. Blankenship¹, Prajakta Shanbhag¹, James Winslow¹, Paula Meek¹, Patrick Blatchford¹, Edward L. Melanson, FACSM¹, Rebecca Boxer². ¹University of Colorado Anschutz Medical Campus, Aurora, CO. ²Kaiser Permanente, Denver, CO. (Sponsor: Edward Melanson, FACSM)
 Email: jennifer.blankenship@cuanschutz.edu
 (No relevant relationships reported)

Physical activity (PA) is an essential behavior to manage health of older adults with heart failure, however, most adults with chronic illness do not adhere to structured exercise programs. Promoting the reduction of sedentary behavior may be an alternative strategy to indirectly increase PA in individuals with heart failure.

PURPOSE: To compare two behavior interventions (reducing sitting time [RST] vs. adding structured exercise [EX]) aimed to increase PA in individuals with heart failure.

METHODS: Older adults (N=56, age ≥ 65 years) with heart failure (NYHA class II or III) and at risk for physical disability were randomized to a 3-month behavior intervention. RST: reduce sedentary behavior by replacing sitting time with standing/stepping time whenever possible and interrupting prolonged sitting bouts. EX: gradually increase structured exercise time to 30 minutes per day. Physical function (timed up and go test [TUG]) was assessed at baseline and at 3 months post interventions. Participants wore the activPAL for 7 days at baseline and during the final week of RST and EX to measure PA/sedentary behavior. Time spent sitting, standing and stepping (expressed as mean daily minutes and percent of waking wear time), and daily step counts were quantified using activPAL data. Differences between groups were determined using linear mixed models with repeated measures. Data are presented as mean \pm SD.

RESULTS: At baseline participants spent the majority of waking time sitting (626.4 \pm 112.2 min, 67.3 \pm 10.9%). On average, participants spent 25.8 \pm 9.3% time (237 \pm 84.6 min) standing and very little stepping (63.6 \pm 27.2 min, 7.3 \pm 3%, 2237 \pm 1140 steps). The majority of sitting time was accumulated through prolonged bouts lasting >30 minutes in duration (381 \pm 131.4 min). At 3 months, there was no significant change in time spent sitting (RST: 69.3 \pm 10.5%, EX: 65.7 \pm 8.5%), standing (RST: 23.8 \pm 8.8%, EX: 26.9 \pm 6.3%), or stepping (RST: 6.9 \pm 3.0%, EX: 7.4 \pm 3.5%) in RST and EX. Similarly, TUG was not significantly different at 3 months in either intervention (baseline: 13.2 \pm 2.8, month 3: 13.5 \pm 4.0).

CONCLUSION: Neither RST or EX changed behavior or physical function after 3 months in HF patients. More work is needed to understand the barriers preventing behavior change in participants to improve the adoption of PA interventions in HF patients.

Association Of Muscle Quality And Prevalence Of Diabetes In Older Adults

Alberto Palmero Canton, Angélique Brellenthin, Duck-Chul Lee, FACSM. Iowa State University, Ames, IA. (Sponsor: Duck-Chul Lee, FACSM)
 Email: albertpc@iastate.edu
 (No relevant relationships reported)

PURPOSE: Diabetes is often related to the skeletal muscle; however, studies investigating individual muscle characteristics like strength or mass on diabetes have produced mixed findings. The purpose of this study was to evaluate the association of muscle quality (MQ), a metric that reflects both muscle strength and mass, with diabetes in older adults.

METHODS: This cross-sectional study included 468 older adults aged ≥ 65 years (mean age 72 years; 55% women) enrolled in the Physical Activity and Aging Study (PAAS). Participants were excluded if they had heart attack, stroke, or cancer in the past 5 years. MQ was defined as the ratio of the combined left and right handgrip strength maximums divided by the combined lean mass of the left and right arms (measured by DEXA). Diabetes was defined by self-report, fasting glucose ≥ 126 mg/dl, or taking insulin, or other diabetes medications. Logistic regression was used to calculate the odds ratios (ORs) and 95% confidence intervals (CIs) of diabetes among sex-specific tertiles (thirds) of MQ. Covariates included sex, age, smoking, heavy alcohol consumption, body fat percentage, hypertension, hypercholesterolemia, and physical activity (daily steps).

RESULTS: Forty-five (9.6%) participants had diabetes. Compared to the lower third of MQ, the middle and upper thirds had 0.53 (0.26-1.07) and 0.25 (0.11-0.61) times lower odds of diabetes after adjusting for age and sex (model 1); 0.58 (0.28-1.21) and 0.26 (0.11-0.66) times lower odds of diabetes after adjusting for body fat percentage, smoking, heavy alcohol consumption, and physical activity (model 2); and 0.60 (0.28-1.25) and 0.28 (0.11-0.71) times lower odds of diabetes after adjusting for all confounders including hypertension and hypercholesterolemia (model 3). There was an inverse linear trend between MQ tertiles and diabetes ($p=0.02$).

CONCLUSIONS: Higher MQ was associated with a reduced likelihood of diabetes in older adults. MQ could be an indicator of diabetes, but future prospective studies are needed.

(No relevant relationships reported)

Cardiovascular baroreflex sensitivity (BRS), a risk factor for cardiovascular disease, declines with advancing age. Previous studies reported that the higher amount of moderate- to vigorous-intensity physical activity is associated with the better BRS. However, the associations of BRS with sedentary behavior (SB) and light-intensity physical activity (LPA), which occupies most of the waking time, are not fully understood. **PURPOSE:** The purpose of this study was to examine the associations of BRS with SB and LPA in the middle-aged and older adults. **METHODS:** A total of 162 individuals (64 ± 9 years) participated in this study. Spontaneous BRS was evaluated by transfer function analysis of a 5-minute continuous data (blood pressure and cardiac period) in the supine position. The SB and LPA time were assessed using triaxial accelerometers. The oxygen consumption at ventilation threshold (VO_{2VT}) was measured as the cardiorespiratory fitness parameter. **RESULTS:** A series of multiple linear regression analysis revealed that SB and LPA time were significantly associated with BRS after adjusting for potential covariates such as age, sex, body mass index, heart rate, systolic blood pressure, smoking, menopausal, and medication status ($\beta = -0.205, P = 0.018; \beta = 0.208, P = 0.018$). These associations remained significant after adjusting for the VO_{2VT} ($\beta = -0.189, P = 0.030, \beta = 0.200, P = 0.022$). **CONCLUSIONS:** This cross-sectional study found that the time spent in SB and LPA are independently associated with BRS and suggests that lower SB and higher LPA contribute to maintaining BRS in middle-aged and older adults.

Perceptions Regarding Physical Function Limitations Among Midlife And Older Adults In A Health Ministry Program

Brittney S. Lange-Maia¹, Sheila A. Dugan¹, Daniel R. Lindich¹, Samantha Marinello², Catherine Banks³, Elizabeth B. Lynch¹. ¹Rush University Medical Center, Chicago, IL. ²University of Illinois at Chicago, Chicago, IL. ³Greater Galilee Baptist Church, Chicago, IL.
Email: brittney_lange-maia@rush.edu
(No relevant relationships reported)

Limitations in physical function lead to decreased quality of life and are predictive of disability, hospitalizations, and mortality. We previously assessed physical function as part of a health-screening program with African American churches in Chicago's West Side. Screenings revealed high rates of functional limitations among midlife and older adults. **PURPOSE:** To inform the development of a church-based intervention that aims to improve physical function. **METHODS:** We conducted 6 focus groups with a total of 40 participants age 40+ from our partner churches and communities who reported difficulty with physical function. Focus groups were audio recorded and transcribed. Qualitative data analysis software was used to analyze the data and generate themes and sub-themes.

RESULTS: Participants (mean age 64.4 ± 11.0 years, range 42-92 years, 88% female) described that physical function limitations negatively impacted their ability to live a full life and play an active role in their family, church, and community. Faith and prayer helped participants cope with limitations and pain. Participants expressed that it is important to keep moving, both from an emotional (not giving up) and physical (moving to prevent more limitations) standpoint. Some participants shared positive experiences making home modifications to adapt to limitations (like installing grab-bars), however, a prevailing opinion was that using mobility aids—especially canes or walkers—leads to further functional decline. An additional emerging theme was the desire to learn how to move better; for example, how to safely navigate stairs or strengthen muscles to facilitate daily activities. Participants expressed frustration that their communities were not conducive to physical activity (particularly in regards to safety and lack of facilities for physical activity), but generally welcomed programs in the church focused on physical function and activity.

CONCLUSIONS: Community-based programs focusing on reducing physical function limitations are needed, and delivering programs through the church is a

potentially acceptable strategy. Along with using physical activity to promote physical function, integrating concepts from physical and occupational therapy could also be beneficial.

Three Months Of Aerobic Exercise Training Improves Vascular Endothelial Function In Overweight/obese Older Adults

Kevin D. Ballard, FACSM, Gabrielle Volk, Alexandra Hopun, Olivia Henderson, Kyle L. Timmerman, FACSM. *Miami University, Oxford, OH.*
Email: ballarkd@miamioh.edu
(No relevant relationships reported)

Aging and overweight/obesity (OW/O) are associated with insulin resistance (IR) and impaired vascular endothelial function (VEF), potentially increasing cardiovascular disease (CVD) risk. Aerobic exercise training is an effective intervention to improve IR and VEF. **PURPOSE:** To determine changes in IR and VEF following aerobic exercise training in older OW/O adults. We hypothesized that 3 months of aerobic exercise training would improve IR and VEF, independent of weight loss. **METHODS:** Preliminary data are from 11 (8 women) older OW/O adults participating in a randomized clinical trial: 4 control (CON) (64 ± 8 y; BMI = 32.7 ± 3.3 kg/m², body fat = 41.5 ± 8.0%) and 7 exercisers (EX) (62 ± 4 y; 32.2 ± 5.5 kg/m², 40.2 ± 10.2%). Supervised aerobic exercise training consisted of moderate-intensity (40-60% heart rate reserve) cycling performed 3 d/wk for 3 months. Body mass and composition were measured by bioelectrical impedance analysis following an overnight fast. Brachial artery flow-mediated dilation (FMD), a non-invasive measure of VEF that predicts incident CVD events, was assessed by a trained technician using high-resolution ultrasonography. HOMA-IR was calculated from fasting blood glucose and insulin. **RESULTS:** No between group differences were detected at baseline. Compared to baseline, no changes were found in CON at 3 months (all $P \geq 0.19$). However, percent body fat (40.2 ± 10.2% vs. 38.9 ± 10.4% for baseline vs. 3 months, respectively ($P < 0.05$)) and brachial artery FMD (3.2 ± 3.0% vs. 5.1 ± 2.8% ($P < 0.05$)) improved at 3 months in EX. No other time effects were found in EX. **CONCLUSIONS:** Preliminary data from our ongoing clinical study show that 3 months of moderate-intensity aerobic exercise training improves body composition and VEF in OW/O older adults. Continued recruitment of participants completing a longer exercise training program (i.e., 6 months) will more definitely determine the beneficial impact of aerobic exercise training on VEF and related cardiometabolic risk factors.

IMPROVEMENT THROUGH MOVEMENT: INVESTIGATING FITNESS, FUNCTIONAL CONNECTIVITY, AND COGNITION IN OLDER ADULTS

Katherine Mary McDonald¹, Sheeba Anteraper¹, Michelle Voss², Susan Whitfield-Gabrieli¹, Kirk Erickson³, Charles Hillman¹, Edward McAuley⁴, Arthur Kramer¹. ¹Northeastern University, Boston, MA. ²University of Iowa, Iowa City, IA. ³University of Pittsburgh, Pittsburgh, PA. ⁴University of Illinois, Champaign, IL.
(No relevant relationships reported)

As the U.S. population has grown older, it has become increasingly crucial to understand age-related brain alterations in an effort to ameliorate and protect against normal, and especially abnormal, decline. Prior research suggests that physical activity acts on and benefits similar cognitive constructs most commonly affected by cognitive aging. **PURPOSE:** The purpose of this investigation was to advance understanding of functional connectivity as a possible mechanism by which fitness protects and restores brain function. **METHODS:** Data were collected as a part of the "Fit and Active Seniors Trial" between 2015-2018. We evaluated functional brain changes in participants before and after they took part in an exercise intervention. Seventy-seven older adults that had pre- and post-intervention MRI scans, fitness data, and behavioral data were included. All participants (age range: 60 - 80 years, 69% female) were randomized into either an aerobic walking group (n=34) or active control stretching and toning group (n=43) that met three times a week for six months. **RESULTS:** Cardiorespiratory fitness (measured by VO_2 peak) significantly improved within-groups pre/post ($p = .001$), but not between-groups ($p = .374$). Multi-voxel pattern analysis (MVPA) was performed on the resting-state functional MRI scans to detect variability in whole-brain patterns of connectivity. There were no significant between-group differences in functional connectivity at pre-test. However, several significant clusters in the Default Mode Network were identified between-groups at the 6-month post-intervention, including regions of the hippocampus (height threshold $p < 0.001$, cluster threshold $p < 0.05$ corrected for false discovery rate). These MVPA-derived hippocampal voxels were then used for whole-brain seed-to-voxel analysis for post-hoc characterization, and results indicated that increases in between-group functional connectivity were driven by the walking group ($p < 0.01$). **CONCLUSION:**

This research adds to the understanding of the mechanism by which physical activity protects and restores brain function, which ultimately could lead to efforts preventing, minimizing, and improving age-related cognitive decline.

Muscle Capacity, Adiposity And Change In Dynamic Function After Weight Loss In Older Women

Isaura M. Castillo-Hernández, Ewan R. Williams, Chad R. Straight, Alison C. Berg, Rachelle A. Reed, Ellen M. Evans, FACSM. *University of Georgia, Athens, GA.*

Email: isaura.castilloh27@uga.edu

(No relevant relationships reported)

PURPOSE: Improving muscle capacity (strength or power) can improve lower-extremity physical function (LEPF); however, it is unclear how concomitant weight loss impacts this relationship. Exercise training during weight loss may have complicated implications for changes in LEPF due to changes in both muscle capacity and adiposity. This study aimed to determine if adiposity influences the relationship between change in muscle capacity and LEPF in inactive overweight older women following a weight loss and exercise program.

METHODS: Inactive overweight/obese older women ($n = 38$; BMI = 30.0 ± 4.4 kg/m²; 69.3 ± 4.1 y) completed a 6-month weight loss and supervised exercise intervention. Maximal leg strength (STR) was measured via isokinetic dynamometry and leg power (POW) via leg extension power rig. Body composition was assessed via DXA. LEPF was assessed using the 6-minute walk (6MW) and 8-foot Up-and-Go (UPGO), which are both dynamic physical functional tests. **RESULTS:** Body weight ($-9.6 \pm 3.5\%$), fat mass (-6.8 ± 2.4 kg) and leg lean mass (-0.3 ± 0.5 kg) decreased (all $p < 0.01$). Muscle STR (19.7 ± 35.4 N-m) and POW (23.3 ± 39.1 watts) improved (both $p < 0.01$). 6MW (58.9 ± 33.7 m) and UPGO (-0.84 ± 0.74 s) also improved (both $p < 0.01$). Linear regression analysis (unstandardized betas) indicated: a) changes in STR predicted changes in 6MW ($\beta = 0.505$, $R^2 = 0.15$, $p < 0.05$) and changes in UPGO ($\beta = -0.012$, $R^2 = 0.19$, $p < 0.05$); and b) changes in POW predicted changes in 6MW ($\beta = 0.310$, $R^2 = 0.12$, $p < 0.05$) but was not related to changes in UPGO ($R^2 = 0.05$, $p = 0.22$).

There was a strong trend for the addition of change in fat mass to the predictive model to improve the explained variance in LEPF outcomes by 7-10% ($p = 0.053-0.06$).

CONCLUSIONS: Increases in muscle capacity, especially strength, improve dynamic measures of LEPF in response to a weight loss and exercise program in older women, even in the presence of leg lean mass loss. The influence of reductions in fat mass on measures of LEPF appears to be of lesser importance compared to improvements in muscle capacity given the relative amount of variance explained. More research is needed to inform best practice for exercise prescription to enhance LEPF in older adults, especially under weight loss conditions.

Validity Of Combined Heart Rate And Accelerometry To Predict Activity Energy Expenditure In Older Adults

Alina Rieckmann¹, Bas Jordan², Frederike Burczik¹, Jacqueline Meixner¹, Christian Thiel¹. ¹*University of Applied Sciences Bochum, Bochum, Germany.* ²*Zuyd University of Applied Sciences, Heerlen, Netherlands.*

Email: alina.rieckmann@hs-gesundheit.de

(No relevant relationships reported)

Purpose The present study compared physical activity related energy expenditure (PAEE) as predicted by group calibrated algorithm combining accelerometry and heart rate.

Methods N=45 older adults with and without cardiac risk performed a protocol consisting of simulated daily living activities (resting period, light, moderate and vigorous physical activity including walking in different speeds and stair climbing) and a cycle ergometer test (25W + 25W every 2 minutes). PAEE was concurrently assessed by indirect calorimetry (IC) and by combined heart rate (HR) plus uniaxial accelerometry (ACC). Raw HR and ACC data were transformed to PAEE using a published branched equation model. Estimated and measured PAEE were compared using Bland-Altman plots.

Summary of results Preliminary results of n=12 healthy older adults without cardiac risk (8 male and 4 female, 71.9 ± 5.2 years) showed lower ACC+HR-estimated PAEE for clustered activities (including cycle ergometer test) and resting period (clustered activities 2.17 ± 1.17 Kcal/min; resting period 0.19 ± 0.17 Kcal/min) than PAEE measured by IC (clustered activities 2.93 ± 1.27 Kcal/min; resting period 0.61 ± 0.40 Kcal/min). The Bland & Altman plots' limits of agreement were between -2.28 and +0.94 kcal/min. Visual inspection showed that the dispersion of the absolute differences between ACC+HR and IC seemed to increase with higher measured values. The correlation between combined ACC+HR-PAEE and IC-PAEE was $r_p = 0.86$.

Conclusion First results indicate that branched equation models based on combined ACC+HR registrations may underestimate PAEE in older people but appear sufficiently valid for the assessment of mean PAEE in groups. If the relatively large limits of agreement were to persist throughout this ongoing study, they would

indicate a limited validity of existing ACC+HR branched equations for the individual assessment of PAEE in older adults. More research is needed to determine whether combined ACC+HR assessments are superior to simple ACC to measure physical activity in older adults.

The Impact Of Sedentary Behavior On Mental Health For Older Adults: A Longitudinal Study Of University Retirees In Beijing China

Xiaolu Feng¹, Wenya Du¹, Jun Qiu¹, Hongjun Yu¹, Weimo Zhu, FACSM². ¹*Tsinghua University, Beijing, China.* ²*University of Illinois at Urbana-Champaign, Champaign, IL.* (Sponsor: Weimo Zhu, FACSM)

Email: fengxiaolu@vip.163.com

(No relevant relationships reported)

PURPOSE: This study was to estimate the impact of physical activity on mental health for older adult from a 5-year follow-up Chinese university retirees study during 2011-2016 in Beijing.

METHODS: We conducted follow-up health surveys on 5503 (2080 males & 3423 females; aged 67.6 ± 8.2 , Height = 162.2 ± 7.5 cm, Weight = 63.3 ± 9.8 kg, BMI = 24.1 ± 43.2) older adults enrolled at Beijing from 2011 to 2016. Sedentary behavior (SB) were measured by the translated "Physical Activity Scale for the Elderly" (PASE) questionnaire (Washburn et al., 1993). Mental health were assessed by self-reported self-rated mental health scores (MHSs) in the participants. The data were analyzed using linear individual fixed-effect regressions.

RESULTS: The average time spent in sedentary behavior for men was 12.9 ± 3.3 hours/day. The mean mental health was 2.4 ± 0.7 scores. SB were negatively associated with mental health for older adults. A one hour increase in SB was associated with a decrease in mental health score by 0.25 (95% [CI] = 0.19, 0.32). A one hour increase in SB was associated with a decrease in mental among females and males by 0.25 (95% [CI] = 0.16, 0.33) and 0.27 (95% [CI] = 0.16, 0.37), respectively.

CONCLUSIONS: SB may decrease mental health among older adults in Chinese follow-up study. Increasing SB in male's older adults tended to decrease their mental health more than females.

Processing Accelerometer Data For Older Adults With COPD

Katelyn Webster, Ronald Dechert, Janet L. Larson. *University of Michigan, Ann Arbor, MI.*

Email: katewebs@umich.edu

(No relevant relationships reported)

Sedentary behavior (SB) is often measured with ActiGraph (AG) accelerometers, but the ActivPAL (AP) is the gold standard device. AG processing methods, including cut-points for SB, filters, and non-wear time algorithms, influence sedentary time estimates. The optimal protocol for processing AG sedentary time is not known and may be population specific. **PURPOSE:** To identify which combination of AG SB cut-point, filter, and non-wear algorithm produces sedentary time estimates that have the strongest agreement with AP-measured sedentary time in a sample of 45 older adults with chronic obstructive pulmonary disease (COPD). **METHODS:** Participants wore AG and AP monitors simultaneously for 7 days. AG data was processed using all possible combinations of two SB cut-points (<50 counts per minute [cpm] and <100 cpm), two filters (normal and low frequency extension [LFE]), and non-wear algorithms with three different lengths (60, 90, and 120 minutes) for a total of twelve processing methods. Concordance correlations between AP-measured SB time and each of the twelve AG SB estimates were calculated using the Bland-Altman method. **RESULTS:** Concordance correlation coefficients range from 0.579 to 0.772 (see table). The AG cut-point of <50 cpm and the LFE filter resulted in the highest concordance correlations. Correlations were similar between the three non-wear algorithms lengths. **CONCLUSIONS:** Although the AP is the gold standard for measuring SB, the AG may be an acceptable substitute when optimal processing methods are used. This analysis provides evidence supporting the use of the AG cut-point of <50 cpm for SB and the LFE filter for older adults with COPD. The optimal non-wear algorithm length is less clear.

Processing Method (Filter & Non-Wear Algorithm Length)	Concordance Correlation (SE)	Mean Difference AG-AP(SD)	95% Limits of Agreement
<50 cpm cut-point			
Normal & 60 min.	0.654 (0.031)	40.0 (107.8)	-171.2, 251.2
Normal & 90 min.	0.659 (0.030)	59.3 (102.7)	-142.1, 260.6
Normal & 120 min.	0.666 (0.029)	69.0 (98.5)	-124.1, 262.2
LFE & 60 min.	0.762 (0.024)	18.2 (94.8)	-167.6, 204.0
LFE & 90 min.	0.762 (0.024)	28.0 (94.1)	-156.5, 212.5
LFE & 120 min.	0.772 (0.023)	33.6 (90.5)	-143.8, 211.0
<100 cpm cut-point			
Normal & 60 min.	0.579 (0.033)	69.2 (112.3)	-151.0, 289.3
Normal & 90 min.	0.577 (0.032)	88.4 (106.8)	-120.9, 297.7
Normal & 120 min.	0.581 (0.031)	98.2 (102.3)	-102.4, 298.7
LFE & 60 min.	0.696 (0.027)	55.0 (97.7)	-136.6, 246.6
LFE & 90 min.	0.687 (0.028)	64.8 (96.9)	-125.2, 254.8

Sedentary Behavior And Physical Function In Older Adults Following A Randomized Controlled Sedentary Behavior Intervention

Kevin M. Crombie, Neda E. Almassi, Brianna N. Leitzelar, Kelli F. Koltyn, FACSM. *University of Wisconsin - Madison, Madison, WI.* (Sponsor: Kelli Koltyn, FACSM)
(No relevant relationships reported)

Older adults represent the fastest growing segment of the population, and spend approximately 60-70% of their waking hours engaging in sedentary behaviors, which increases their risk for functional decline and negative health outcomes. Therefore, interventions aimed at breaking up sedentary time by standing up and moving more throughout the day may have important health benefits for older adults, although well-designed randomized controlled trials (RCT) are limited. **PURPOSE:** To examine the effectiveness of a four week sedentary behavior intervention to reduce sedentary time and improve physical function in 56 community dwelling older adults (M age = 74 ± 7). **METHODS:** The intervention consisted of 4 weekly workshop sessions plus a refresher session, and was delivered by community partners from 3 different State Aging Units. A RCT design was implemented assessing sedentary behavior and physical function prior to, immediately following, and at follow-up (8-weeks after intervention). Sedentary time (mins/day) was obtained via accelerometers/inclinometers, and physical function (balance, gait speed, chair stands) was assessed with the Short Physical Performance Battery. Outcomes were analyzed between and within groups using mixed-design repeated measures ANOVAs. **RESULTS:** There were significant ($p < .05$) group x time interactions for sedentary time, balance, gait speed, and chair stands. Analysis of simple effects indicated the intervention group significantly ($p < .05$) reduced their overall sedentary time by a mean of 68 min/day immediately following the intervention compared to a mean increase of 17 min/day in the control group. Also, the intervention group significantly ($p < .05$) improved their physical function following the intervention compared to no significant change in the control group. However, there was a significant ($p < .05$) increase in sedentary time from post-intervention to follow-up for the intervention group, with only a 17 min/day decrease from baseline. **CONCLUSION:** Results indicate that our sedentary behavior intervention reduced sedentary time and improved physical function in older adults, although it appears that additional research is needed in order to ensure this positive behavior change is maintained over time.

Supported by the National Institute on Aging Grant R21AG054916.

Clinically Meaningful Changes In Mobility After An Exercise Program For Older Adults

Randall J. Gretebeck, Kimberlee A. Gretebeck. *Marquette University, Milwaukee, WI.*
 Email: randall.gretebeck@marquette.edu
(No relevant relationships reported)

Aging is associated with a progressive decline in muscle strength and mass, eventually leading to reduced functional ability and disability. Regular physical activity can slow this inevitable decline and promote physical wellbeing, improve physical function and reduce risk of chronic diseases in older adults. However, meaningful improvements in physical function for individuals in response to a training stimulus are often missed when only group effects are considered. **PURPOSE:** to examine interindividual variation in changes in functional ability in response to a 10-week exercise intervention designed to improve physical function in older adults. **METHODS:** 97 older adults (age = 72.7 yrs ± 7.9); BMI = 32.3 ± 7.2) completed the 10-week Physical Activity for Seniors for Life (PALS) group exercise and lifestyle behavior change program. 6MW (distance covered in 6 minutes), and UGS (meters/second (m/s) to walk 6 m distance) were measured before and after the exercise program. **RESULTS:** There was a significant ($p < .05$) improvement in 6mw and UGS for the group ($m = 60.2$ meters and 0.1045 m/s respectively). For 6mw, 27% did not improve more than 20 meters (>20 meters is small meaningful change), 23% improved between 20 and 50 meters, and 50% improved more than 50 meters (>50 meters is substantial meaningful change). For UGS 38% showed less than 0.05 m/s improvement (0.05 m/s is small meaningful change), 12% improved between 0.05 and 0.1 m/s, and 47% improved more than 0.1 m/s (0.1 m/s is substantial meaningful change). **CONCLUSIONS:** Consideration of individual variability is important in establishing the clinical meaningfulness of improvements in physical function in response to exercise programs designed for older adults.

Associations Between Sedentary Behavior And The Out-of-pocket Health Care Expense Of Chinese Older Adults

Jun Qiu¹, Hongjun Yu¹, Yonghong Wang², Weimo Zhu, FACSM³.
¹Tsinghua University, Beijing, China. ²Nanjing Forestry University, Nanjing, China. ³University of Illinois at Urbana-Champaign, Champaign, IL. (Sponsor: Weimo Zhu, FACSM)
(No relevant relationships reported)

PURPOSE: To investigate the relationship between sedentary behavior (SB) and medical expenses of older adults in China.

METHODS: We conducted a survey with 4,248 older adults (1776 males & 2472 females, 69.31 ± 7.57 yr., Height = 170 ± 5.9 cm, Weight = 67.7 ± 10.4 kg, BMI = 23.3 ± 3.35) from 47 cities in China between 2013 and 2014. SB were measured by the translated "Physical Activity Scale for the Elderly" questionnaire (Washburn et al., 1993). Healthcare costs were assessed by self-reported out-of-pocket health care expenses across outpatient care, inpatient care, medication, and formal caregiver expenses. The data were analyzed using interval regression.

RESULTS: The average time spent in sedentary behavior for the Chinese older adults men was 12.32 hours/day and the mean yearly medical expenses was 7460.1 \pm 2468.8 RMB. One hour spent on SB was associated with an increase of RMB 255.56 in annual health care expense (95% confidence interval [CI] = RMB 135.25 - 255.56), RMB 86.63 in outpatient care (95% [CI] = RMB 53.45 - 119.82), RMB 32.53 in medication (95% [CI] = RMB 5.72 - 59.33), RMB 164.21 in inpatient care (95% [CI] = RMB 81.84 - 246.57), and RMB 0.48 day in formal caregiver by (95% confidence interval [CI] = 0.28 - 0.68). One hour spent on SB was associated with an increase of out-of-pocket medical expenses by RMB 230.49 (95% [CI] = RMB 72.00 - 388.98) and 319.23 (95% [CI] = RMB 133.41 - 505.05) in annual health care expense, RMB 95.93 (95% [CI] = RMB 51.38 - 139.88) and 86.81 (95% [CI] = RMB 36.66 - 136.97) in outpatient care, RMB 22.57 (95% [CI] = RMB -11.95 - 57.09) and 49.08 (95% [CI] = RMB 6.24 - 91.53) in medication, RMB 190.17 (95% [CI] = RMB 82.18 - 298.17) and 130.48 (95% [CI] = RMB 2.20 - 258.75) in inpatient care, and RMB 0.60 (95% [CI] = 0.28 - 0.92) and 0.49 (95% [CI] = 0.22 - 0.98) day in formal caregiver among females and males, respectively.

CONCLUSIONS: The Chinese older adults who had more SB tended to have higher out-of-pocket medical expenses. Increasing SB in male's older adults tended to increase their out-of-pocket more than females.

2694 Board #155 May 29 10:30 AM - 12:00 PM
Influences Of Baduanjin Exercise On The Blood Lipids And Serum IL-6,apn In The Olders

Xu shou sheng¹, Wang Yan¹, Zhou Xiao Qing¹, Wang Hong Jun². ¹Beijing Sport University, Beijing, China. ²China Renmin University, Beijing, China. (Sponsor: Zhengzhen Wang, FACSM)
 Email: 13522668308@139.com
 (No relevant relationships reported)

PURPOSE: To explore the effects of Baduanjin on the blood lipids and serum IL-6,APN in the olders.

METHODS: The healthy old people without regular exercise behaviour were selected from China Renmin University community, and were divided into the control group (C group, n=9) and the exercise group (E group, n=6) after the physical examination. The subjects took part in the study and gave formal consent. E group carried out Baduanjin for 4 months, while C group kept their routine life especially the daily exercise habits. Body composition and blood were tested at the beginning of the study and four months later, and the blood examination including the blood lipids and serum IL-6,APN.

RESULTS: 1. Body composition Compared with the baseline examination, the lean body mass of 4 months later in E group increased significantly ($P < 0.05$), while the C group showed little difference. E group's body fat percentage and visceral fat mass decreased ($P < 0.01$); and in C group, fat free mass, visceral fat mass hardly changed except the body fat percentage decline ($P < 0.05$). 2. Blood Lipids The baseline total cholesterol (TC) of E group were higher than the C's, and after the 4-month intervention, the E's TC went down (5.13 ± 1.07 vs 4.92 ± 0.74) ($P < 0.05$), but the C's elevated ($P < 0.05$), with the result that E's TC were lower than C's at the 4-month later ($P < 0.01$). Between the two groups, HDL-C and LDL-C also showed great difference, especially E's HDL-C displayed health promotion effects. 3. Serum Factors (1) IL-6 of the both group declined after 4-month duration, with E's $P < 0.01$ and C's $P < 0.05$. (2) Great difference were found between the two groups according to the baseline test of serum APN, but after 4-month E's APN elevated and higher than C's ($P < 0.01$), while the C's went down ($P > 0.05$).

CONCLUSIONS: Regular exercise of Baduanjin could improve the body composition, change the blood lipids. Furthermore, Baduanjin exercise had good effect on the regulation of IL-6,APN, which in turn may alleviate the chronic gradual low inflammation inside the olders. Home-based Self-managed Older Adult Exercise Program Improves Physical Activity Status And Sleep Quality

Jeffrey E. Herrick, Sean M. Collins, Caitlyn Harper, Michela Cholak. University of Lynchburg, Lynchburg, VA.
 Email: herrick_je@lynchburg.edu
 (No relevant relationships reported)

Aging promotes a decline in overall physical activity (PA) status and is associated with an increase in risk for numerous adverse health conditions, including poor sleep. Poor sleep quality is a commonly reported complaint in older adults that may accelerate many prevalent health conditions and limit daily functional capacity. Habitual PA for older adults has been shown to increase physical fitness with corresponding reductions in adverse health risks, to include sleep quality. However, a barrier for older adult habitual PA are the commonly reported barriers such as time, cost, transportation and poor education on exercise prescription. A possible approach to minimize barriers to habitual PA may be a home-based self-managed exercise program.

PURPOSE: The purpose of this ongoing pilot study is to describe the effects of a home-based self-managed exercise program on physical activity status and sleep quality.

METHODS: 7 older-adults (68±4.7 years) were recruited from area community centers and participate in 6-weeks of the home-based self-managed University of Lynchburg Active Aging Program (ULAAP). Endurance, strength, and balance exercises were prescribed using the National Institute of Aging's Exercise & Physical Activity Guidelines. Sleep parameters were measured with the Pittsburgh Sleep Quality Index (PSQI) and physical activity status was measured with the International Physical Activity Questionnaire (IPAQ).

RESULTS: There was a significant increase in MET-minutes at the end of 6-weeks of PA (pre 2729±2507, post 5626±2850 MET-minutes of light to vigorous exercise; $p = 0.024$). Weekly time spent sitting was reduced (TSit pre 29±12.05, post 18.14±9.8 hours per week, $p = 0.008$). There was a significant increase in sleep quality following 6-weeks of PA (PSQI pre 7.8±3.3, post 4.7±1.6, $p = 0.024$), an increase in total sleep time (TST pre 6.5±0.5, post 7.5±0.5 hours, $p = 0.048$) with no change in sleep efficiency (SE pre 73.9±13%, post 84.7±6.6%, $p = 0.09$).

CONCLUSION: Home-based self-managed older-adult exercise program increased overall physical activity status and reduced sedentary time with improved sleep quality. Our result suggests an older-adult self-managed low-impact multimodal exercise program may positively improve sleep quality.

Does A Recumbent Lateral Stability Trainer Improve Balance Scores Among Older Adults Within 4 Weeks?

Andrew Shim¹, Samantha Prichard¹, David Newman², Carly Lara¹, Mike Waller³. ¹College of Saint Mary, Omaha, NE. ²Florida Atlantic University, Boca Raton, FL. ³Arkansas Tech University, Russellville, AR.
 Email: ashim@csm.edu
 (No relevant relationships reported)

Falls are the leading cause of fatal and non-fatal injuries for older Americans. Modifying exercise programs to address balance and lower body strength would vastly improve stability and functional movement. Past literature has shown balance and strength are important in preventing falls, but few studies have focused on developing strength in a lateral plane compared to an anterior/posterior plane. **PURPOSE:** To determine if a lateral pedal recumbent training device that allows lower limb movement in a horizontal plane can improve balance scores among older adults in 4 weeks. **METHODS:** A two group experimental-control multivariate design was selected for the study. All subjects (n = 56) were between the ages of 59-80 years and without any physical limitations or medical issues. All participants were divided into 2 equal groups, pre-tested and post-tested on a computerized posturography plate (Bertec, Inc. Columbus, OH.) to determine Center of Pressure scores with eyes opened (EOSS), Center of Pressure scores with eyes closed (ECSS), Center of Pressure scores with eyes open perturbed surface (EOPS), and Center of Pressure scores with eyes closed perturbed surface (EPCS). The experimental group used the lateral trainer for 15 minutes, 3 times per week, for 4 consecutive weeks while the control group maintained a sedentary lifestyle. A repeated measures MANOVA was used to determine significance between the two groups within the 4 balance assessments. **RESULTS:** There were no significant main treatment effects for either group ($p = .221$). There were statistically significant differences over time for EOPS ($p = .047$) and EPCS ($p = .047$). Likewise, there were statistically significant differences for each univariate outcome with EOSS ($p = .045$), ECSS ($p = .033$), EOPS ($p = .010$), and EPCS ($p = .026$). Statistical power was achieved ($> .98$) for both univariate and multivariate measures. The multivariate outcome for group x time interaction accounted for 15.2% more variance than time alone (28.1%) for the experimental group alone. **CONCLUSION:** A recumbent lateral stability device can improve balance scores among older adults within 4 weeks of training, 3 x week for 15 minutes.

Comparative Responses To A Social Media Enhanced Physical Activity Program In Older Males And Females

Carlos X. Torres-Ramos¹, Rachel E. Salyer², Isaura M. Castillo-Hernandez². ¹University of Puerto Rico-Mayagüez, Mayagüez, PR. ²University of Georgia, Athens, GA. (Sponsor: Dr. Ellen M. Evans, FACSM)
 Email: carlos.torres70@upr.edu
 (No relevant relationships reported)

Most older adults fail to adhere to the multicomponent (aerobic, muscle strengthening, balance training), 2018 Physical Activity (PA) Guidelines. Thus, effective and sustainable multicomponent PA programs that promote adherence in older adults remains a public health priority, especially for females given their higher rates of physical inactivity and risk for physical disability compared to males. **PURPOSE:** To examine if sex/gender influences the effects of a multicomponent 10-week PA intervention grounded in Social Cognitive Theory and augmented with social media (Facebook) on program attendance and engagement, PA behaviors, muscle capacity, and lower extremity physical function (LEPF) in older adults. **METHODS:** Physically inactive older adults (71.3 ± 4.3 yo; n=28, 64% female) completed a 10-week multicomponent PA program that included 1) a twice weekly supervised exercise class (muscle strength and balance training) with PA behavior education, 2) Facebook engagement, and 3) an unsupervised walking prescription. PA behaviors were assessed via accelerometer, questionnaires and pedometer step count logs. Conventional measures of leg strength and power along with a battery of LEPF tests were also employed [6-minute walk (6MW), 8-foot up and go (UPGO), chair stands (CHAIR), and transfer task (TRANSFER)]. A two-way [Gender (G) x Time (T)] ANOVA was utilized to determine significance of change. **RESULTS:** There was a trend for higher class attendance in females compared to males (96.7±3.8% vs. 92.0±6.7%, $p = 0.06$). Females also had a 2.3-fold greater engagement in Facebook compared to males ($p = 0.01$). Males and females improved PA behaviors similarly (T $p < 0.05$; G x T and G $p > 0.05$). Muscle capacity improved similarly (T $p < 0.05$) with males, as expected, having higher leg strength and power (G $p < 0.05$; G x T $p > 0.05$). Regarding LEPF, improvements occurred in 6MW, UPGO and TRANSFER (T $p < 0.05$; G x T $p > 0.05$).

with males also having higher functional capacity, as anticipated, in 6MW, UPGO, and CHAIR (G $p < 0.05$). **CONCLUSION:** A 10-week PA/EX program improves PA behavior, muscle capacity, and LEPP similarly in older males and females. Implementation science research is needed to develop effective and sustainable multicomponent PA programs for older adults which may differ by social factors in older females compared to males.

Estimated Cardiorespiratory Fitness, Comorbidity, And Health-related Quality Of Life In Korean Older Adults With Diabetes

Inhwan Lee, Youngyun Jin, Jeonghyeon Kim, Minjung Kang, Yujin Lee, Hyunsik Kang. *Sungkyunkwan University, Suwon, Korea, Republic of.*
 (No relevant relationships reported)

Purpose: Health-related quality of life (HRQoL) is a multidimensional subcomponent of quality of life that can be affected by health or health-related interventions. This study examined whether or not non-exercise-based estimation of cardiorespiratory fitness (eCRF) mediates the relationship of comorbidity with HRQoL in Korean older adults with diabetes.

Methods: Data from a subgroup ($n=1371$) of Korean older adults with diabetes and age of ≥ 60 years (55% women) who participated in the 2008-2011 Korean National Health and Nutritional Examination Survey were used in this analysis. HRQoL was assessed with the EuroQoL-5 dimensions index and EuroQoL visual analogue scale. Comorbidity was defined as physician-diagnosed chronic conditions. eCRF was assessed with a non-exercise regression equation derived from sex, age, body mass index, and self-reported physical activity. The SPSS macro provided by Preacher and Hayes was used to test whether CRF mediated the relationship between comorbidity and HRQoL at $p=0.05$.

Results: The total effect of the presence of comorbidities on HRQoL was significant (path c: $\beta=-2.670$, 95% CI= $-3.868 \sim -1.472$, $p < 0.001$). The presence of comorbidities was negatively related to eCRF in HRQoL model (path a: $\beta=-0.529$, 95% CI= $-0.652 \sim -0.404$, $p < 0.001$). The effect of eCRF as a mediator on HRQoL was also significant (path b: $\beta=1.434$, 95% CI= $0.928 \sim 1.940$, $p < 0.001$). The mediation analysis using the bootstrapping method (5,000 resamples) showed that eCRF mediated the relationship between the presence of comorbidities and HRQoL in Korean older adults (path ab: $\beta=-0.757$, 95% CI= $-1.104 \sim -0.453$, Sobel test $Z=-2.753$, $p < 0.001$). In addition, a direct effect of the presence of comorbidities on HRQoL was also significant (path c': $\beta=-1.913$, 95% CI= $-3.128 \sim -0.698$, $p < 0.05$).

Conclusions: The current findings suggest that cardiorespiratory fitness (CRF) can contribute to explain the relationship between comorbidity and HRQoL in Korean older adults with diabetes, implying the clinical relevance that promotion of CRF may have an impact beyond physical health in the patients. This study was supported by the National Research Foundation funded by the Korean Government (NRF-2019R111A1A01043771).

Stand Up Now: A Sedentary Behavior Intervention In Older Adults Of Moderate-to-low Physical Function

Katie J. Thralls¹, Susan S. Levy². ¹Seattle Pacific University, Seattle, WA. ²San Diego State University, San Diego, CA.
 Email: kthralls@spu.edu
 (No relevant relationships reported)

BACKGROUND: Sedentary behavior (SB) is associated with impaired physical function, falls, and higher mortality in older adults, which in turn leads to loss of physical independence. **PURPOSE:** The purpose of this feasibility study was to examine the efficacy of a 12-week intervention, Stand Up Now (SUN), to reduce SB and improve physical function and mobility in older adults of moderate-to-low function residing in assisted living facilities. **METHODS:** SUN included two intervention groups: one group focused on reducing total sedentary time (SUNST); one group focused on increasing sit-to-stand (STS) transitions (SUN^{STS}). All participants ($N=71$; $M_{age}=87 \pm 7$ yrs) received weekly health coaching over 12 weeks. SB, physical function, and mobility were measured at baseline, 6, and 12 weeks via the activPALTM, Short Physical Performance Battery (SPPB), and the 8-foot up-and-go (8ft UG), respectively. Linear Mixed Models were used to examine the efficacy of SUN on outcome variables over time. **RESULTS:** Both groups significantly decreased sedentary time (1.3 ± 0.3 hrs, $p < 0.001$) and increased standing time (0.5 ± 0.2 hrs, $p < 0.02$) at 6 weeks that was maintained at 12 weeks, compared to their baseline. SUN^{STS} significantly increased STS transitions at 6 weeks (5.4 ± 4.1 , $p < 0.001$) while SUNST had no changes (0.5 ± 3.1 , $p > 0.9$). No changes were noted in stepping time (0.04 ± 0.08 hrs, $p < 0.15$) or steps (261 ± 234 , $p < 0.14$) per day in either group. Both groups improved physical function from baseline to 6 weeks (1.5 ± 0.4 points, $p < 0.001$) that was maintained at 12 weeks. No significant changes were seen in mobility for either group

(0.5 ± 1.5 sec, $p > 0.05$). **CONCLUSIONS:** SUN demonstrates the efficacy to improve SB and physical function and may be a promising strategy to maintain function for activities of daily living to prevent loss of independence in older adults.

Association Between Air Pollution And Daytime Sleep Duration: A Follow-up Study Of Chinese Older Adults In Beijing

Miao Yu¹, Hongjun Yu², Weimo Zhu, FACSM³. ¹Renmin University of China Libraries, Beijing, China. ²Tsinghua University, Beijing, China. ³University of Illinois at Urbana-Champaign, Urbana, IL. (Sponsor: weimo zhu, FACSM)
 Email: yumiao@ruc.edu.cn
 (No relevant relationships reported)

PURPOSE: This study was to estimate the association between air pollution and daytime sleep duration for older adults from the 5-year follow-up Chinese older adult surveys during 2011-2016 in Beijing, China.

METHODS: We conducted follow-up health surveys on 5503 (2080 males & 3423 females; Age 67.6 ± 8.2 yr., Height = 162.2 ± 7.5 cm, Weight = 63.3 ± 9.8 kg, BMI = 24.1 ± 4.3 in 2011) older adults enrolled at Beijing from 2011 to 2016, once per year. Sleep duration was measured using the Pittsburgh Sleep Quality Index (PSQI), which has been validated in China to measure sleep duration. Corresponding levels of average hourly PM2.5 ($\mu\text{g}/\text{m}^3$) on the survey days were gathered from data provided by the mission China air quality monitoring program run by the US Department of State in Beijing. The data were analyzed using the linear individual fixed-effect regressions.

RESULTS: The average time spent in daytime sleep for older adults was 0.6 ± 0.5 hours/day. The mean PM2.5 was 123.9 ± 52.5 ($\mu\text{g}/\text{m}^3$). Daytime sleep was positively associated with air pollution for older adults. Overall, an one standard deviation (SD) increase in air pollution concentration in PM2.5 ($56.6 \mu\text{g}/\text{m}^3$) was associated with an increase in daytime sleep hours by 1.49 (95% confidence interval [CI] = 1.17, 1.81), with the corresponding increases in females and males were 0.91 (95% [CI] = 0.33, 1.49) and 1.82 (95% [CI] = 1.34, 2.30) hours, respectively.

CONCLUSIONS: Increased air pollution seems led more daytime sleep among older Chinese adults and the impact on males was more significant than females.

Concurrent Training Reduces Depressive Symptoms In Mexican Female Older Adults

Ermilo Canton Martínez¹, Iván Rentería¹, José Moncada Jiménez², Patricia Concepción García Suárez¹, Luis Mario Gómez Miranda³, José Antonio De Paz Fernández⁴, Alberto Jiménez Maldonado¹. ¹Universidad Autónoma de Baja California, Ensenada, Baja California, Mexico. ²Universidad de Costa Rica, San José, Costa Rica. ³Universidad Autónoma de Baja California, Tijuana, Baja California, Mexico. ⁴Universidad de León, León, Spain.
 Email: ecanton@uabc.edu.mx
 (No relevant relationships reported)

Nearly 35% of Mexican older adults (OA) are diagnosed with mild depression. Exercise has shown positive effects on reducing depression symptoms in OA. The correlation between physical function, body composition and mild depression risk in healthy OA has been neglected in Mexico. **PURPOSE:** To determine the effect of a concurrent-training exercise program (CTEP) on mild depression in Mexican female OA. A secondary aim was to determine the correlation between physical function, body composition and depressive symptoms in OA following a CTEP. **METHODS:** Twenty-one females (age = 64.0 ± 5.38 yr., weight = 72.0 ± 12.6 kg, BMI = 29.0 ± 4.7 kg/m²) participated in the study. Before (Pre) and after (Post) the CTEP, participants were measured on depression by the *Hamilton Depression Rating Scale* (HAM-D), body fat, muscle mass [MM], physical function by the *Senior Fitness Test*, and aerobic capacity by the 6-min walking test (6MWT). The CTEP consisted in two days of aerobic exercise and one day of resistance training performed for 50-min at moderate intensity (12 to 14 on Borg's RPE scale) for 12-weeks. Paired t-tests were computed to compare pre- to post-CTEP effects, and Spearman correlations studied the association between body composition, physical function and depression scores using the GraphPad PRISM 5.0 software. **RESULTS:** The CTEP reduced HAM-D scores (Pre = 15.7 ± 4.5 vs. Post = 10.3 ± 5.3 pts., $p = 0.0001$), improved upper-body strength (Pre = 15.1 ± 2.6 vs. Post = 18.9 ± 3.0 reps, $p = 0.0001$), lower-body strength (Pre = 12.0 ± 2.4 vs. Post = 14.5 ± 2.9 reps, $p = 0.0001$), agility (Pre = 6.5 ± 0.9 vs. Post = 6.0 ± 0.9 s, $p = 0.0001$), and MM (Pre = 21.8 ± 2.9 vs. Post = 22.26 ± 3.1 kg, $p = 0.002$). No significant changes were found in aerobic capacity (Pre = 587.9 ± 164.4 vs. Post = 619.6 ± 144.9 m, $p = 0.06$) and body fat (Pre = 31.0 ± 8.8 vs. Post = $30.8 \pm 9.1\%$, $p > 0.05$). The HAM-D scores were inversely correlated with upper-body strength ($r = -0.53$, $p = 0.002$) and lower-body strength ($r = -0.64$, $p = 0.002$), and directly correlated to agility ($r = 0.50$, $p = 0.0004$). **CONCLUSIONS:** A CTEP reduced depressive symptoms in Mexican female OA in

spite of lack of changes in body composition. The increased physical function relates to a reduction in depressive symptoms; thus, highlighting the importance of improving functionality in OA.

Associations Of Physical Activity And Sedentary Behavior With The Onset Of Long-term Care Need In Community-dwelling Independent Japanese Older Adults: The Tsuru Study

Shinichiro Sato¹, Takuya Yamada², Mutsumi Nakamura³, Yuta Nemoto⁴, Noriko Takeda⁵, Kazushi Maruo⁶, Yoshiharu Fukuda², Susumu S. Sawada, FACSM⁴, Yoshinori Kitabatake⁷, Takashi Arao⁸. ¹University of Human Arts and Sciences, Saitama, Japan. ²Teikyo University, Tokyo, Japan. ³Tohto University, Chiba, Japan. ⁴Waseda University, Saitama, Japan. ⁵Kogakuin University, Tokyo, Japan. ⁶University of Tsukuba, Ibaraki, Japan. ⁷Saitama Prefectural University, Saitama, Japan. ⁸Meiji Yasuda Life Foundation of Health and Welfare, Tokyo, Japan.

(No relevant relationships reported)

Limited data are available for the examination of the associations of physical activity (PA) and sedentary behavior (SB) with the onset of long-term care need (OLCN) in older adults. **PURPOSE:** The purpose of this study is to investigate the independent and joint associations of moderate PA (MPA) and SB on the OLCN among Japanese elderly in the local municipality. **METHODS:** A cohort of 3937 Japanese elderly men [median (IQR) age 74 (65–99) years] and 2048 women [median (IQR) age 74 (65–99) years] without certification of long-term care need have reported on PA and SB in 2016. The participants were divided into three categories (0 min/week: MPA-none, 1–299 min/week; MPA-M₁, ≥ 300 min/week; MPA-M₂) based on MPA and two groups based on median (200min/week) of SB (SB-M₁, SB-M₂). The OLCN was defined as the time of the certification of long-term care need by the Certification Committee of Needed Long-Term Care in the municipality. The information of the OLCN during follow-up from 2016 to 2018 was obtained from the person in charge of Tsuru city. Hazard ratios (HR) and 95% confidence intervals (95% CI) for the OLCN were obtained using proportional hazard models while adjusting for sex, age, educational level, marital status, activities of daily living, and history of current illness. **RESULTS:** During the 2-year follow-up period, 517 participants obtained certification of needed long-term care. With the independent effects of MPA and SB, using the MPA-none as reference, HRs and 95% CIs for MPA-M₁ and MPA-M₂ were 0.67 (0.51–0.86) and 0.48 (0.35–0.66), respectively (P for trend < 0.001) and using lower SB (SB-M₁) as reference, HR and 95% CI for higher SB (SB-M₂) was 0.74 (0.58–0.94). With the joint effects of MPA and SB, using MPA-none & SB-M₁ as reference, HRs and 95% CIs for MPA-none & SB-M₂, MPA-M₁ & SB-M₁, MPA-M₁ & SB-M₂, MPA-M₂ & SB-M₁, and MPA-M₂ & SB-M₂ were 0.62 (0.44–0.87), 0.58 (0.42–0.82), 0.50 (0.34–0.74), 0.39 (0.26–0.60), and 0.39 (0.25–0.62), respectively. **CONCLUSIONS:** These results suggest that MPA and SB might be independent factors for the onset of long-term care need and that these factors might have a strong joint effect on the onset.

 (No relevant relationships reported)

The effect of different types of contractions (eccentric/concentric) has gained attention in the last years, where it was suggested that eccentric training would promote better results regarding the muscle mass development, affecting the functionality of older adults. **PURPOSE:** Analyze the effect of 16-weeks of eccentric and concentric training on functionality and body composition of older adults. **METHODS:** Sixteen-weeks of strength training with an emphasis on concentric/eccentric contractions were applied in 35 older adults, which were randomized into three groups: Eccentric Training N=12 (ET); Concentric Training N=12 (CT) and Control Group = 11 (CG). Functionality was analyzed through the timed up and go test (TUG), 30-second chair test, and handgrip strength. Body composition was accessed through the amount of lean body mass (LBM) and body fat (%BF), analyzed with a Bioelectrical Impedance Analysis (BIA). Muscle thickness of biceps brachialis (BTH)

and femoris rectus (FRTH) were accessed with an ultrasound (Eco III CHSON). All the analyses were made at the beginning of the intervention and after 16-weeks of the training protocol.

RESULTS: TUG was significantly lower in ET and CT compared to CG after 16 weeks of strength training (13.6 ± 0.7 to 17.02 ± 0.7 and 13.8 ± 0.6 to 17.02 ± 0.7 with p=0.001) without significant difference between intervention groups. The 30-second chair test was significantly higher in ET and CT compared to CG (11.9 ± 0.73 to 6.1 ± 0.71 with p= 0.001 and 10.9 ± 0.64 to 6.1 ± 0.71 with p=0.01 respectively). Hand Grip was statistically better in ET and CT compared to CG (21.5 ± 0.50 to 17.2 ± 0.5 with p= 0.001 and 21.4 ± 0.46 to 17.2 ± 0.5 with p=0.002). The %BF reductions were 6% higher in ET compared to CT and 19% higher compared to CG. BTH was significantly higher in ET compared to CG (0.46 ± 0.143 cm to 0.08 ± 0.137 with p=0.001) without differences between ET and CT. FRTH was significantly higher at the end of 16 weeks in ET and CT compared to the pre-test (2.40 ± 0.2 to 2.67 ± 0.19 cm with p=0.001 and 2.35 ± 0.193 to 2.61 ± 0.1 cm with p=0.05), with the control group presenting a significant decrease (2.58 ± 0.19 cm to 2.36 ± 0.18 cm with p=0.001) **CONCLUSIONS:** Both ET and CT promote improvements in the functionality and the body composition of older adults; however, no statistical change was observed between ET/CT groups.

A Moderate-length Exercise Training Intervention Reduces Serum Protein Status In Older Adults

Patricia Concepción García Suárez¹, Cristina Esmeralda Zazueta Soto¹, Ermilo Canton Martínez¹, Ivan Rentería¹, Alberto Jiménez Maldonado¹, Patricia Radilla Chávez¹, David Osvaldo Martínez Corona¹, José Moncada Jiménez². ¹Universidad Autónoma de Baja California, Ensenada, Baja California, Mexico. ²Universidad de Costa Rica, San José, Costa Rica. Email: patricia.garcia@uabc.edu.mx
 (No relevant relationships reported)

Chronic exercise programs improve cardiometabolic status, lipid profile and glycemic control in older adults. These interventions usually last between 15 to 24 weeks with a frequency of three to four times per week, jeopardizing the older adult continuous interest in the program and eventually its adherence. **PURPOSE:** To determine the effect of a moderate-length exercise program on metabolic and protein status older adults. **METHODS:** Thirty-five volunteers (age= 62.6±7.3 yr., BMI= 28.3±3.9 kg/m², Body fat = 39.8±7.1%) completed the exercise program. Measures of body composition (body fat, BMI, muscle mass [MM] and muscle index [M_{index}]), serum total proteins (TP), albumin (ALB), glucose (GLU), triglycerides (TG), total cholesterol (TC), 6-min walking test (6MWT), and estimated VO_{2max} were recorded before and after completion of the program. Each training session was performed for 50-min at moderate intensity (12 to 14 on Borg's RPE scale), with three-days of aerobic exercise and two-days of resistance training, accumulating five sessions per week for 12 weeks. Paired Student's t-tests with Cohen's d effect sizes were computed on JASP v0.9.2 software. **RESULTS:** No significant changes were observed on BMI (Pre= 28.3 ± 3.9 vs. Post= 28.6 ± 4.2 kg/m², p= 0.067, d= -0.35), body fat (Pre= 39.8 ± 7.1 vs. Post= 40.1 ± 7.4%, p= 0.63, d= -0.09), MM (Pre= 22.7 ± 4.1 vs. Post= 22.8 ± 4.1 kg, p= 0.15, d= -0.27), M_{index} (Pre= 9.1 ± 0.9 vs. Post= 8.0 ± 3.1 kg/m², p= 0.059, d= 0.34), TC (Pre= 183.2 ± 68.9 vs. Post= 175.8 ± 115 mg/dL, p= 0.70, d= 0.06), 6MWT distance (Pre= 480.7 ± 105.7 vs. Post= 461.8 ± 123.6 m, p= 0.9, d= 0.02) and VO_{2max} (Pre= 29.4 ± 6.9 vs Post= 28 ± 7.1 mL·kg⁻¹·min⁻¹, p= 0.46, d= 0.13). Significant reductions were found on GLU (Pre= 98.0 ± 54.4 vs. Post= 77.5 ± 45.3, p= 0.011, d= 0.45), TG (Pre= 122.2 ± 82.0 vs. Post= 99.5 ± 66.5 mg/dL, p= 0.05, d= 0.34), TP (Pre= 6.5 ± 2.6 vs. Post= 4.3 ± 1.5 mg/dL, p= 0.0001, d= 0.90), and ALB (Pre= 3.7 ± 1 vs. Post= 2.9 ± 0.9 mg/dL, p= 0.0001, d= 0.80). **CONCLUSION:** A moderate-length 12-week exercise program improved GLU and TG levels in older adults. The lowered TP and ALB with a concomitant trend of the M_{index} reduction suggest a metabolic overreaching tending to undernutrition after the program.

2705 Board #166 May 29 10:30 AM - 12:00 PM
Physical Activity Intervention Access Effects Physical Function And Physical Activity Outcomes In Older African Americans

Kimberlee A. Gretebeck, Randall J. Gretebeck. Marquette University, Milwaukee, WI. Email: kimberlee.gretebeck@marquette.edu
 (No relevant relationships reported)

Older African Americans (AA) have the highest rates of disability of any racial/ethnic group and <25% meet recommended PA levels. Overcoming barriers to PA adoption and maintenance continues to be a major challenge without clear consistent solutions. Self-regulation strategies have shown promise in PA behavior change interventions. **Purpose:** To examine the effect of location of a PA intervention on physical function, PA and self-regulation in older AAs using a pre-post study design. **Methods:** Sedentary older AA participants (n=40) participated in an evidence-based behavioral intervention

aimed to improve physical function outcomes (usual gait speed, UGS; 6-minute walk, 6MW; timed up and go, TUG), self-regulation and long-term maintenance of PA (CHAMPS questionnaire). The PA intervention was held in government subsidized housing complexes where participants lived, (PA-Apt, n=22 participants) or in convenient neighborhood facilities (PA-NF, n=18 participants). The intervention, based on self-regulation principles, includes a 10-week moderate intensity strength, flexibility and aerobic group exercise class 60 minutes/3 times/week plus a 6-month maintenance period with bi-weekly coaching telephone calls. Measures were assessed at baseline, after the 10-week group exercise class, and following a 6-month maintenance period. Participants included 6 males and 34 females, aged 59-85 years (M=67.9, sd=6.40) with mean BMI 34.23 (sd=9.19, range 14.99-57.47). 47.5% were morbidly obese. **Results:** Significant improvements ($p<.01$) in TUG, UGS, 6MW, moderate intensity and total PA and self-regulation were found immediately following the 10-week group class and were maintained for 6 months ($p<.01$) in the PA-Apt group. Significant improvements ($p<.05$) in TUG and 6MW were found immediately following the 10-week group class and were maintained for 6 months ($p<.01$) while moderate intensity and total PA and self-regulation were significant after the 10-wk intervention but were not maintained after 6 months in the PA-NF groups. No significant difference was found for UGS. **Conclusions:** Providing PA interventions in facilities where older AAs live may be more effective in improving and maintaining PA than in convenient community settings near where participants live.

Physical Activity Format Does Not Influence Daily Energy Expenditure Or Sleep Quality In Older Adults.
 Michael J. Turner, FACSM, Ali Wilcox. *UNC Charlotte, Charlotte, NC.*
 Email: miturner@uncc.edu
 (No relevant relationships reported)

PURPOSE: Regular physical activity is known to prevent chronic diseases, improve cognitive function, increase self-efficacy, decrease mortality, and reduce risk of falls in older adults. Sleep quality, quantity, and waking behaviors have been associated with increased quality of life, improved health, and increased overall energy expenditure. Sixty percent of older adults report not participating in regular physical activity or exercise, yet those who are active utilize different programming options (structured and unstructured) to achieve this behavior. We assessed how different activity options impact sleep behaviors, step counts, and perceived quality of life in the older adult population.

METHODS: Forty-five older adult volunteers were divided into one of four groups based on their current structure of physical activity participation (Supervised Exercise (SE), Independent Exercise (IE), Active Lifestyle (AL), or Control (C)). Subject group selection was the result of answering "Do you exercise?" If answered "Yes", then asked "Is it instructed (SE) or independent (IE)?" If answered "No", then asked "Do you lead an active lifestyle (AL) or not (C)?" Nine men and 36 women participated, with the following representation per group - SE: 73.9±6.6yrs (n=13), IE: 76.5±6.1yrs (n=13), AL: 79.9±9.6yrs (n=10), C: 69.8±5.8yrs (n=9). Energy expenditure and sleep quality were measured through a wrist worn Fitbit Charge HR for seven days. Perceived health status and sleep quality were assessed with the SF-36 & PSQI, respectively.

RESULTS: Groups were not different by height, or weight ($p>0.05$), but SE and C were found to be younger ($p=0.02$) than the IE and AL groups. No differences were observed between groups for energy expenditure, sleep quality, or sleep efficiency ($p>0.05$). The AL group noted lower pain ($p=0.002$) and physical functioning ($p=0.01$) compared to the remaining groups. Trends toward statistical significance between groups were observed with perceived health perception ($p=0.07$) and steps ($p=0.07$). **CONCLUSIONS:** The current study suggests that energy expenditure and sleep quality are not related to structure of physical activity programming with older adults.

Epidemiological Differences In Young, Middle-aged, And Older Golfers' Injuries
 Andrea Fradkin, FACSM. *Bloomsburg University, Bloomsburg, PA.*
 Email: afradkin@bloomu.edu
 (No relevant relationships reported)

Golf is a popular sport worldwide, yet injuries sustained during golf rarely receive the same recognition as sports perceived as violent or strenuous. However, golf injuries have been shown to occur with a high incidence. **PURPOSE:** To examine the differences in young, middle-aged, and older golfers' injury profiles, as well as determining factors associated with injury risk. **METHODS:** Amateur golfers aged 18 years and older who played golf on a regular basis completed a questionnaire documenting their previous 12-month injury status and associated golfing demographics. **RESULTS:** This study consisted of 1170 golfers (young: 127 females, 110 young males; middle-aged: 450 females, 165 males; older: 227 females, 91 males), with median handicaps of young, middle-aged, and older females (12, 16,

17), and males (15, 12, 13) respectively. Younger golfers sustained significantly more injuries than middle-aged and older golfers (females 45.7%, 32.7%, and 27.3%; males 45.5%, 44.5%, and 35.2%, respectively). Odds ratio (OR) analysis showed that older golfers were less likely to report sustaining an injury than younger (OR: 0.813, $p=0.008$) and middle-aged golfers (OR: 0.745, $p=0.029$). Of the 423 injuries (36.5%), 72.8% impacted the golfers' performance or participation. Overall, the lower back was the most frequently injured region (27.6%), with strains the most frequent type of injury (49.5%), but differences in injury profiles were evident between groups. Older golfers sustained significantly more knee, groin, and hip injuries, whereas younger golfers sustained significantly more wrist, foot, and ankle injuries (all $p\leq 0.01$). Other than age, hours of play / week, hours of practice / week, and total golf participation hours / week were all significant, independent predictors of injury. The Hosmer and Lemeshow test indicated an acceptable goodness of fit of the model ($p=0.878$). **CONCLUSIONS:** Injuries occur to golfers of all ages and have a significant impact upon golfers' lives. Before suggesting that golfers limit their golf participation, other injury prevention avenues must be investigated to ensure that participation in physical activity is not viewed as harmful. Further, prevention strategies need to be investigated in relation to specific characteristics of golfers to attempt to reduce injury risk.

2708 Board #169 May 29 10:30 AM - 12:00 PM
Comparison Of Omentin-1 And Insulin Resistance Markers In Different Physical Activity Levels Older Adults
 Shuo Li¹, Jingjing Xue², Ping Hong³. ¹Shanghai University of Sport, Shanghai, China. ²Beijing Dance Academy, Beijing, China. ³Winter Sports Management Center of the General Administration of Sport of China, Beijing, China.
 (No relevant relationships reported)

PURPOSE: Omentin-1 is a good adipokine produced by omental adipose tissue and plays a pivotal role in regulating the insulin resistance. The aim of this study was to compare serum omentin-1 concentration together with insulin resistance markers in active-obese, inactive-obese, normal-weight Chinese older adults.

METHODS: 128 older adults (men: n=32, women: n=96) were recruited to participate in this study. Subjects were divided into the following three groups. 1) active-obese (n=49, age=63±6years; BMI=25.9±2.3kg/m²); 2) inactive-obese (n=48, age=66±6years; BMI=26.5±2.4kg/m²); 3) normal-weight (n=31, age =64 ±5years; BMI=21.1±1.5kg/m²). ActiGraph GT3X-BT triaxial accelerometers were used to measure the levels of physical activity. We define it as active subjects based on average number of minutes spent on the moderate-to-vigorous physical activity (180min/week). Venous blood samples were collected to measure omentin-1, insulin and glucose levels. The homeostasis model assessment of the insulin resistance (HOMA-IR) was calculated as the following formula: fasting glucose (mmol/L) × fasting insulin (mU/L)/22.5.

RESULTS: The results showed that omentin-1 concentration was significantly lower in obese than normal-weight group (17.1±12.4 vs. 24.2±13.4ng/ml, $p<0.01$). Meanwhile, Glucose, insulin and HOMA-IR was significantly higher in obese than in normal-weight group (5.3±1.2 vs. 4.8±0.4mmol/L, 7.9±3.8 vs. 4.7±1.9μU/mL, 1.94±1.18 vs. 1.00±0.39, both $p<0.05$). However, there was no significant difference between serum omentin-1 levels and glucose in active-obese and inactive-obese groups (both $p>0.05$). Insulin and HOMA-IR in active-obese were significantly lower than inactive-obese group (7.2±3.1 vs. 8.8±4.3μU/mL, 1.68±0.90 vs. 2.22±1.41, both $p<0.05$).

CONCLUSIONS: Our results suggested that physical activity can improve the negative effects of obesity on insulin resistance markers, but did not affect the concentration of omentin-1 significantly of obese older adults.

ACKNOWLEDGMENTS: This study was supported by Ministry of Science and Technology of the People's Republic of China (Grants No.2013FY114700).

Investigation Of The Relationship Between Physical Activity, Inflammatory Proteins And Adiponectin In Older Adults
 Arushi M. Chalke, Callen R. Conroy, Adam D. Mandrell, Alexandra I. Hopun, Kevin D. Ballard, FACSM, Kyle L. Timmerman, FACSM. *Miami University, Oxford, OH.*
 Email: chalkeam@miamioh.edu
 (No relevant relationships reported)

INTRODUCTION: Chronic low-grade inflammation (CLGI) is a hallmark of aging and significantly contributes to the development and progression of numerous chronic diseases including cardiovascular disease (CVD) and diabetes. CLGI is frequently defined as elevated serum levels of inflammatory proteins including C-reactive protein (CRP) and interleukin-6 (IL-6). Physical activity has been reported to have anti-inflammatory effects. **PURPOSE:** To explore the relationships among habitual physical activity, inflammation, and cardiometabolic risk factors in older adults. **METHODS:** In 82 subjects (23 male / 59 female) body composition was determined

(bioelectrical impedance) and physical activity was measured objectively (7-day accelerometry) as well as subjectively (Community Health Activities Model for Seniors (CHAMPS)). Enzyme-Linked Immunosorbent Assays (ELISA) were used for the quantitative measurement of IL-6, CRP, and anti-inflammatory, adipose tissue derived hormone, adiponectin. Blood lipids were also measured utilizing a point-of-care analyzer. Partial correlations (controlling for age and sex) were used to analyze associations. **Summary of RESULTS:** Mean values included: age (68.5 ± 6.3 yr); body fat percentage (31±11%); accelerometry (cts/min: 114.1±56.5, sedentary-to-moderate ratio: 12.8±6.1); CHAMPS (2,328±1658 kcal/wk); CRP (1.5±1.6 mg/dL); IL-6 (4.2±1.0 ng/mL); adiponectin (11.2±6.0 µg/mL); LDL (114±28 mg/dL); and HDL (62±17 mg/dL). CRP was significantly ($p < 0.05$) correlated with body fat percentage ($r = 0.54$), HDL/LDL ($r = 0.42$), IL-6 ($r = 0.37$), and adiponectin ($r = -0.25$). IL-6 was significantly correlated with body fat percentage ($r = 0.24$), activity counts/min ($r = -0.27$), and LDL/HDL (0.29). Adiponectin was significantly correlated with body fat percentage ($r = -0.35$), CHAMPS ($r = 0.28$), and HDL ($r = 0.51$). **CONCLUSION:** The average CRP value for this population of older adults is indicative of moderate risk for the development of CVD. The correlations reported here are supportive of previous research suggesting that body composition and physical activity level are important determinants of inflammatory profile and disease risk. This project was funded by an NIH grant 1R15AG055923-01

Effect Of Exercise On Cardiovascular Risk Factors In Older African American Couples: A Pilot Study

Chloe Selyse Jones. *University of Tennessee, Knoxville, TN.*
 (Sponsor: Lyndsey Hornbuckle, FACSM)
 (No relevant relationships reported)

Chloe S. Jones and Lyndsey M. Hornbuckle, FACSM; University of Tennessee, Knoxville; Knoxville, TN

Background: African Americans (AAs) have higher rates of obesity and several cardiovascular disease (CVD) risk factors compared to other races/ethnicities in the U.S. Romantic partners can positively influence health habits, yet their influence on exercise effects is understudied. This study examines the effects of resistance training (RT) and walking on CVD risk factors in older AA couples. **Methods:** Seven (body mass index 31.2±4.3 kg/m²; 6022±1532 average steps/day) AA romantic couples (n=14; 7 females, 7 males; 63.5±8 y) were recruited for a 12-week supervised RT (two days/week) plus unsupervised walking intervention (≥30 minutes, three times/week). Couples were randomized to exercise together (ET) or individually (I). Waist and hip circumferences, body composition via iDXA, and resting blood pressure were assessed. Venous blood was assessed for glucose, hemoglobin A1c (HbA1c), insulin, total cholesterol (TC), high-density lipoprotein cholesterol, triglycerides, C-reactive protein, and fibrinogen. Tests were performed pre- and post-intervention. Repeated measures ANOVA was used to analyze dependent variables. Post hoc paired-samples T-tests were used to determine significant findings. Significance was accepted at $p \leq 0.05$. **Results:** A significant group x time interaction was found for TC with a significant decrease in I (180.8±34.5 to 162.2±28.9), but no other variables. There were significant mean time effects for waist circumference (ET: 97.8±8.4 to 96.2±8.4 cm; I: 97.3±9.2 to 95.7±9.5 cm), body fat (ET: 37.8±6.6 to 37.5±7.1%; I: 38.0±9.4 to 37.0±9.9%), gynoid fat (ET: 39.2±7.8 to 38.9±8.2%; I: 38.5±9.2 to 37.5±9.7%), fat mass (ET: 36.3±5.6 to 35.6±8.1 kg; I: 33.7±9.8 to 32.9±10.4 kg), and HbA1c (ET: 5.8±0.5 to 5.7±0.4; I: 5.9±0.6 to 5.6±0.4%). **Conclusion:** Twelve weeks of RT plus walking may significantly improve several CVD risk factors in older AA couples. The current study is ongoing and will continue to examine the intervention's effects in a larger sample.

Muscle Quality Predicts Improvements In Transfer Task Performance After Weight Loss In Older Women

Ewan R. Williams, Isaura M. Castillo-Hernandez, Chad Straight, Alison Berg, Rachelle A. Reed, Ellen M. Evans, FACSM.
University of Georgia, Athens, GA. (Sponsor: Ellen M Evans, FACSM)
 Email: erw201@me.com
 (No relevant relationships reported)

Purpose: The contributions of weight loss and exercise to improvements in physical function in older adults remains debated and of high public health importance. Physical function tasks vary, but an inability to complete those most simple in life can be highly distressful for older individuals. The Transfer Task (TT), simple to administer, assesses an individual's ability to stand up from the floor, but whether weight or fat loss (i.e., the load to be moved) or improved muscle quality (i.e., ability to move the load) is more important to successfully complete this task is unclear. This study aimed to examine the relative contributions of changes in muscle capacity and body composition to improvements in Transfer Task performance following a weight loss and exercise program in inactive obese older women.

Methods: Inactive older women (n = 34; BMI = 30.0 ± 4.5 kg/m²; 69.4 ± 4.4 y) completed a 6-month weight loss and supervised exercise intervention. Maximal leg strength (STR) was measured via isokinetic dynamometry and leg power (POW) via leg extension power rig. Fat mass and mineral free lean mass (Leg-MFLM) were assessed via DXA. Muscle quality (MQ) was calculated as a ratio between maximal STR and POW and Leg-MFLM (MQ-STR; MQ-POW). The Transfer Task (TT) required sitting down on the floor and returning to a standing position as quickly as possible.

Results: Body weight (-9.6 ± 3.5%), fat mass (-6.8 ± 2.4 kg), and Leg-MFLM (-0.3 ± 0.5 kg) decreased (all $p < 0.01$). MQ-STR and MQ-POW improved (8.2 and 10.1%, respectively, both $p < 0.001$). TT time improved (-39.0 ± 19.8%, $p < 0.01$). Stepwise linear regression indicated that changes in MQ-POW predicted improvement in TT [unstandardized $\beta = -0.50$, $R^2 = 0.18$, $p = 0.017$]; MQ-STR was excluded from the model. A second stepwise model determined that neither change in weight ($\beta = 0.24$, $p = 0.15$) nor fat mass ($\beta = 0.21$, $p = 0.21$) influenced the predictive relationship between changes in MQ-POW and TT.

Conclusion: Changes in muscle quality based on power independently predicts improvements in transfer task performance. Thus, the ability to move the load appears to be more important than the load to be moved regarding the ability to sit on the floor and return to standing after a weight loss and exercise program for older women.

Are Lower-leg And High Muscle Resistance Training Equally Effective To Adl-related Functional Fitness For Community-dwelling Elderly Females?

Hiroshi Kohno¹, Hidenori Asai². ¹TOYO University Faculty of Human Life Design, Asaka-shi, Saitama, Japan. ²Ehime University, Matsuyama-shi, Ehime, Japan.

Email: kohno@toyo.jp
 (No relevant relationships reported)

PURPOSE: The purpose was to compare the magnitude of lower-leg training program and high muscle training program to ADL-related functional fitness changes for community-dwelling elderly Japanese women.

METHODS: After giving written informed consent, the subjects, unable to stand on one leg for more than 25 seconds with their eyes open, were divided into a lower-leg training group (LLG; 10 females, 72.9±4.2 yrs, BMI 22.1±1.8) and a high muscle training group (TMG; 10 females, 70.6±2.5 yrs, BMI 22.1±1.2). The program was 60min. two times per week for 16 weeks. Each training program consisted of three parts. At first, participants learned about management skills for their physical stiffness. Secondly, they learned each resistance program. LLG participated in the program using unstable disk and elastic band. TMG learned program was to strengthen their thigh muscles with elastic band. Finally, both groups learned a three-minute arm and leg combined exercise program with music. Participants were asked to follow their learned management skill program and resistance program every day and check it on the card. ADL-related functional fitness (sitting & standing time, zig-zag walking time, self-care working time), dynamic balance ability which measured by one-leg standing time with their eyes open and knee extension strength was evaluated. Each measurement items were assessed before and after the intervention period. Student's t-test and two-way repeated measures ANOVA were used to test the effectiveness.

RESULTS: The class participation rates were 82± 4% and 81± 8% and home participation rates were 76± 10% and 72± 15% respectively. ADL-related functional fitness of TMG improved significantly compared to LLG; Sitting & standing time (TMG: 18.6±7.4 to 13.4±6.1 sec., LLG: 16.3±7.4 to 13.8± 5.7sec., $F=18.00$, $P=0.033$), self-care working time (TMG: 16.3±5.3 to 11.3±3.2sec., LLG: 16.1±3.2 to 14.9±4.3sec., $F=17.00$, $P=0.026$), zig-zag walking time (TMG: 15.6±7.2 to 14.2±5.5sec., LLG: 14.2±3.2 to 12.6±3.0sec., $F=0.043$, $P=0.838$). Knee extension strength improved significantly in TMG ($P=0.029$). One-leg standing time with their eyes open improved in LLG ($P=0.038$)

CONCLUSIONS: High-muscle training was found more effective to improve ADL-related functional fitness than lower-leg muscles for community-dwelling females.

 (No relevant relationships reported)

PURPOSE: Ensuring walking is important for health maintenance. However, elderly people, particularly, with advanced articular cartilage degeneration need to deal with mechanical stress applied to their body. In this study we examined the effects of mechanical stress-free walking (MSFW), which was devised to reduce the stress to human body, based on previous our studies. **METHODS:** In the first examination, we introduced the MSFW to two different groups: 1) health exercise/fitness instructors (n=110, mean age=54.1±11.6 years) and 2) the elderly, 65 years and older (n=47, mean age=76.1±6.05 years). The 30-minutes workshop for the MSFW were given to the both groups. The MSFW includes 4 walking tips: 1) walking with the upper body upright, 2) catching the ground softly, 3) taking the width of the left and right feet, and 4) not twisting the knee joints. We compared the length of strides and mechanical stress assessed by 3-D acceleration Safety Walk Navi (Descente Ltd, Tokyo, Japan) before and after intervention in both groups. In the second examination, the same workshop was given to different elderly group (n=17, mean age=75.1±4.86years) for 4 weeks. And we compared the data before and after the 4-weeks intervention. **RESULTS:** In the first examination, the health exercise/fitness instructors reduced the length of strides and the mechanical stress of walking (i.e., forward, upward, downward and lateral accelerations) after receiving the 30-minutes MSFW workshop. However, elderly participants did not reduce the mechanical stress, particularly, downward acceleration (mean: 1.67±0.17 G). In the second examination, elderly group received the 4-weeks MSFW workshop. At the end of the workshop, the length of strides and all the measured accelerations were significantly reduced in the elderly participants (height ratio of stride: from 0.46±0.04 to 0.44±0.04**, forward acceleration: from 0.84±0.36 G to 0.66±0.16 G**, upward acceleration: from 0.56±0.16 G to 0.48±0.13 G**, downward acceleration: from 1.79±0.14 G to 1.74±0.13 G*, and lateral acceleration: from 1.04±0.30 G to 0.80±0.21 G**. (** P<0.01 *P<0.05) **CONCLUSIONS:** The MSFW workshop designed to reduce mechanical stress on a body while walking, was effective in any age groups. Even elderly people can learn and achieve MSFW.

Association Between Lower Extremity Muscular Strength And Functional Performance In Community-Dwelling Elderly

Fernanda Sampaio Teles¹, Viviane Cristina Uliana Peterle², Alan Guimarães³. ¹*University of Brasilia, Brasilia, Brazil.* ²*Health Department of Federal District, Brasilia, Brazil.* ³*Arcorpore Gym, Brasilia, Brazil.*
 Email: fernandasteles@hotmail.com
 Reported Relationships: F.S. Teles: Receipt of Intellectual Property Rights/Patent Holder; E-LASTIC.

The combination of aging with reduced muscle mass and muscle strength results in a higher risk of falls, hospitalizations, dependence, poorer quality of life, and all-cause mortality. Our hypothesis, in the present study, is that the elderly who present higher values in gait speed, as well as lower values in the Time Up and Go test, will have higher values of lower limb muscle strength. **PURPOSE:** To correlate functional capacity of walking and time up and go tests with the maximal isometric lower limb strength test in community-dwelling elderly. **METHODS:** Thirty-two elderly (2 men; age: 72 ± 9.2 yrs; body mass: 66 ± 10.6 kg; height: 152.27 ± 7.79 cm) who attended the *Centro de Convivência do Idoso* located in Paranoá, Brasília, DF participated. The tests were performed in an integrated and dynamic circuit format, where each station had a single evaluator. The maximal isometric muscle strength of lower limbs used the *mid tight pull* position where a traction dynamometer (*E-lastic*) was fixed to the ground by a metal chain and at its other end a hand strap. The elderly were instructed to perform their maximal concentric movement strength with semi-flexed knees and extended arms for 3-5 seconds with verbal encouragement. The muscle strength was measured in kilograms (kg). In the *Walking Test* (TC), the elderly should walk through the distance of 10m as fast as possible. Gait speed (m/s) was calculated. In the *Time Up and Go* (TUG) test, the elderly should get up from a chair without the aid of their arms and walk at a comfortable pace at a distance of three meters, get around an obstacle, return and sit again while time to end the task was measured. A Pearson

correlation coefficient was determined between the maximum isometric strength test and the walking and time up and go tests. The statistical package adopted was SPSS (IBM, version 23). **RESULTS:** The findings revealed a significant and moderate correlation for gait speed and lower limb muscle strength ($r = 0.391$; $p = 0.033$) as well as the functional test and lower limb muscle strength level ($r = -0.376$; $p = 0.041$). **CONCLUSION:** Elderly who had higher lower limb strength values obtained the shortest times in the time up and go test and the highest gait speed in the walking test.

 (No relevant relationships reported)

Resistance training (RT) programs employing an undulating periodization (UP) model have consistently shown to enhance muscle strength and physical performance in both trained and sedentary subjects; however, the effects on an older population are less studied. **PURPOSE:** This research aimed to compare the effects of UP vs. linear training (LT) on strength levels and functional capacity in elderly adults. **METHODS:** Eighteen (n=10, men; n=8, women) untrained elderly individuals (64±2.1years, height=165.12±7.7cm, body mass=72.5±11.4kg) with no previous RT experience were randomly assigned to either a linear training (n=9, LT) or UP (n=9) program. Assessments: Chair stand test (CST), chair sit and reach (CSR), arm curl test (ACM), the 6-min walk test (6MWT), back scratch test right (BST-R), 1RM rowing machine (RM), 1RM vertical bench press (VBP), 1RM leg extension (LEx), 1RM unilateral leg press (ULP) and 1RM squat based on mean velocity concentric. **RESULTS:** According to the analysis ($\Delta = \pm SD$; P ; ES to LT and UP, respectively), there were significant changes in CST (3.8±3.1reps; 0.01; 1.67 and 3±1reps; <0.05; 2.58), ACM (5.1±3.6reps; 0.012; 1.41 and 3.6±0.9reps; <0.05; 2.19), 6MWT (250±92.6m; <0.05; 3.76 and 155.6±52.7m; 0.006; 3.02), BST-R (-2.9±0.8cm; <0.05; -0.45 and -1.2±1.1cm; 0.01; -0.18), BST-L (-3.1±1.4cm; <0.05; -0.78 and -1.3±1.3cm; 0.016; -0.18), 8UG (-1.0±0.0s; 0.005; -1.12 and -0.1±0.9s; 0.705; -0.17); RM (25.6±6.8kg; <0.05; 1.76 and 17.8±7.9kg; <0.05; 1.51), VBP (24.6±17.4kg; 0.011; 1.55 and 23.9±6kg; <0.05; 2.09); LEx (30±9.7kg; <0.05; 1.71 and 14.4±6.3kg; <0.05; 0.76), ULP (45.6±25.1kg; 0.001; 1.38 and 36.7±27.8kg; 0.007; 2.1) and squat (17.2±9.4kg; 0.001; 0.82 and 10.3±3.2kg; <0.05; 0.54). No changes were found in CSR in any group (-3.1±7.2; 0.498; -0.68 and 0.4±2; 0.525; 0.09). There were differences in 6MWT by *Group* and by *Time x Group* ($P=0.013$ and 0.019), in ACM by *Group* ($P=0.020$) and BST-R, BST-L, 8UG y ULE ($P=0.003$, 0.015 , 0.016 , y 0.002). **CONCLUSIONS:** A supervised RT program using either linear or undulating periodized design has positive effects on indicators of functional autonomy and physical fitness in older adults, highlighting that the LT protocol generated the largest in changes.

Physical Fitness Changes In Pre frail Elderly Adults After 4-years'S Participation Of Community-based Health-care Classes

Mieko Shimada¹, Jun Kaneko¹, Makoto Arakawa¹, Mai Kono¹, Nobuko Hongu, FACSM². ¹*Chiba Prefectural University of Health Sciences, Chiba, Japan.* ²*University of Arizona, Tucson, AZ.*
 Email: mieko.shimada@cphu.ac.jp
 (No relevant relationships reported)

PURPOSE: There are few long-term follow-up reports on health status or physical fitness changes in frail elderly adults who are participating in community-based health-care classes. This study aimed to examine physical fitness changes between community-dwelling elderly adults with or without prefrailty after participating in preventive health-care classes for 4 years. **METHODS:** We defined "prefrailty" as grip strength <30 kg for men and <20 kg for women. Subjects were divided into two groups based on grip strength (with or without prefrailty) before the preventive health care classes started. We examined the physical fitness changes (i.e. grip strength and 10-m walking speed) in these two groups. **RESULTS:** Twenty-two men and 43 women participated in the classes for 4 years (2011 to 2015), including 3 men and 6 women with prefrailty. At baseline, grip strength

showed statistically significant differences between groups with or without prefrailty in both men (with: 23.2±3.2 kg, without: 37.3±5.6 kg) and women (with: 13.7±1.2 kg, without: 23.7±3.5 kg). Also, walking speed showed statistically significant difference between groups in both males (with: 1.65±0.22 m/sec, without: 2.06±0.51 m/sec), and females (with: 1.49±0.28 m/sec, without: 1.83±0.25 m/sec). After 4 years, an analysis of covariance using age as a co-variable showed that the changes of grip strength were significantly different between two groups ($p < 0.05$), but the walking speeds were not significantly different between two groups. Changes in walking speed were increased in both groups with or without prefrailty (with: +0.10±0.17 m/s, without: +0.04±0.08 m/s). There were no gender differences in changes of grip strength and walking speed. **CONCLUSIONS:** This is the first demonstration that the long-term participation in preventative health-care classes effectively increased walking speed in elderly adults with and without prefrailty.

(No relevant relationships reported)

Resistance training (RT) has been shown to have positive effects on older adults' health by increasing muscle mass and improving metabolic profile. Nonetheless, the potential benefits of a non-linear RT program on biochemical and physiological health parameters in older individuals are less known. **PURPOSE:** This study assessed the effects of an undulating-periodized (UP) RT program on glucose, cholesterol (total, HDL-c and LDL) and triacylglycerol (TG) concentrations in blood, and arterial blood pressure (BP). **METHODS:** Seventeen ($n=9$ men; $n=8$ women) untrained elderly individuals (64.2±2.0 years, 72.2±10.8 kg; 164.8±7.6 cm; 25.6±2.6 kg·m⁻²) with no previous RT experience were randomly assigned to either a linear training ($n=8$, LT) or UP-RT ($n=9$) program. After 3 weeks of familiarization, all participants performed three RT weekly bouts for 8 weeks. Blood samples were collected pre- and post-study after a 12-hour overnight fast, and biochemical analyses were carried out. Systolic and diastolic BP were measured using a digital sphygmomanometer. Statistical comparison was performed with the paired t test or Wilcoxon, and a repeated measures ANOVA was employed to determine interactions ($Time=pre-test$ vs $test$; $Group=LT$ vs UP and $Time \times Group$). Effect size (ES) was calculated with Hedges g . **RESULTS:** Statistical analysis ($\Delta=X \pm SD$; P ; ES) showed differences on basal glycemia for LT (-11.1±8.1 mg·dL⁻¹; 0.006; -1.61) and UP (-5.7±4.2 mg·dL⁻¹; 0.004; -0.65). There were changes in LDL (LT=-15.1±9.5 mg·dL⁻¹; -1.18; 0.003, UP=-9.4±4.4 mg·dL⁻¹; -0.33; <0.0002), total cholesterol (LT=-21.1±14.6 mg·dL⁻¹; -1.19; 0.005, UP=-10.2±6.2 mg·dL⁻¹; -0.28; 0.001) and TG (LT=-18.3±16.0 mg·dL⁻¹; -0.56; 0.014, UP=-6.7±3.9 mg·dL⁻¹; -0.24; 0.001) in both groups, but HDL-c remained statistically unchanged (LT=-2.6±6.3 mg·dL⁻¹; -0.38; 0.277, UP=3.0±6.8 mg·dL⁻¹; 0.27±0.223). There were no changes on either SBP or DBP in LT (-3.4±8.5 mmHg; -0.25; 0.289, and -3.2±5.7 mmHg; -0.48; 0.079, respectively) but there were in UP (-4.5±4.4 mmHg; -0.56; 0.015, and -4.0±4.3 mmHg; -0.83; 0.023, respectively). No significant between-group differences were found for any variable. **CONCLUSIONS:** A supervised RT program with either linear or UP provides improvements in cardiometabolic markers in older adults and, therefore, health enhancement.

**Concurrent Exercise Improves Blood Pressure, Body
 Composition, Lipids And Fitness Components In
 Elderly Women**

Alexei Wong¹, Song-Young Park², Elizabeth J. Pekas², Ronald J. Headid², John Shin², Arturo Figueroa, FACSM³. ¹Marymount University, Falls Church, VA. ²University of Nebraska-Omaha, Omaha, NE. ³Texas Tech University, Lubbock, TX. (Sponsor: Arturo Figueroa, FACSM)
 Email: awong@marymount.edu

(No relevant relationships reported)

Aging is associated with progressive decline of cardiovascular and muscular health, which affects overall fitness and body composition. It is crucial to prevent or attenuate the negative effects of aging on cardiovascular and muscular health by implementing effective lifestyle interventions, such as exercise training. Several longitudinal studies lasting <16 weeks have shown that aerobic, resistance, and concurrent training (CT),

improve blood pressure (BP), muscle strength and body fat percentage (BF%) in elderly cohorts. However, studies evaluating these adaptations following extensive training periods (≥ 1 year) are currently lacking. **PURPOSE:** The purpose of this study was to evaluate BP, BF%, blood lipids, walking capacity and muscular strength values in elderly women following 1 year of habitual CT. **METHODS:** 101 elderly women [age (77 ± 6 years) and body mass index (24.1 ± 3.8 kg/m²)] were randomized to either CT ($n=57$) or non-exercising control group ($n=44$) for 1 year. Participants in the CT group trained 3/week. CT consisted of moderate aerobic exercise that progressed in duration from 25 to 45 min as well as resistance exercise, which entailed 9 exercises for the major muscle groups using 8-12 repetitions. Brachial BP, BF%, blood lipids, 2-minute walking distance (2MWD) and quadriceps strength were evaluated following 1 year of their assigned intervention. **RESULTS:** Systolic BP (~10 mmHg), BF% (~6%), low-density lipoprotein cholesterol (~15) were significantly ($P < 0.05$) decreased, while 2MWD (~19 meters) and quadriceps strength (~4 Kg) were significantly ($P < 0.05$) increased in the CT group when compared to control. **CONCLUSIONS:** Elderly women in CT group had improved BP, BF%, low-density lipoprotein cholesterol, muscle strength and walking capacity when compared to control counterparts. Habitual CT may protect against the development of hypertension, hypercholesterolemia, obesity and muscle weakness in elderly women.

**Exercise Interventions, Physical Function And Mobility
 After Hip Fracture: A Meta-Analysis**

Xiaorui Zhang¹, William J. Butts², Yushi Hu¹, Tongjian You, FACSM². ¹Chengdu Sport University, Chengdu, China. ²University of Massachusetts Boston, Boston, MA. (Sponsor: Tongjian You, FACSM)

(No relevant relationships reported)

PURPOSE: To conduct a meta-analysis of current evidence regarding the effects of exercise interventions on physical function and mobility in individuals after hip fracture. **METHODS:** This meta-analysis was conducted following the PRISMA guidelines. An electronic search using a number of keywords ("hip fracture" or "trochanteric fracture" or "femoral neck fracture" and "exercise" or "physical activity" or "locomotion" or "movement" and "human" and "randomized controlled trial") in six databases (Pubmed, Embase, Cochrane Library, Web of Science, Clinical and PsycINFO) was performed from their inception to September 2019. Inclusion/exclusion criteria limited articles to randomized controlled trials investigating the effects of exercise interventions on physical function and mobility after hip fracture, compared to non-exercise controls. Standardized mean differences, relative effect sizes (ES; Hedges's) and heterogeneity statistics (I^2) were calculated using a random-effects model. **RESULTS:** Among 2028 citations retrieved, 15 citations (15 studies) met the inclusion criteria, and all were conducted in older adults ($n=1196$, age=80.04±7.72 yrs). The interventions included aerobic exercise only ($n=1$), resistance exercise only ($n=3$), functional exercise only ($n=1$), and various combinations of aerobic, resistance, functional and/or balance exercise ($n=10$). The pooled Hedges's SMD for overall physical function was 0.46 (95% CI=0.27 to 0.65, $p=0.000$, $I^2=58.9\%$) in favor of exercise interventions. Exercise interventions also had a significant effect on mobility (ES=0.22, 95% CI=0.08 to 0.36, $P=0.0\%$). The mean ESs on balance (ES=0.50, 95% CI=0.31 to 0.69, $I^2=11.1\%$), muscle strength (ES=0.30, 95% CI=0.14 to 0.47, $I^2=0.0\%$), activities of daily living (ES=0.20, 95% CI=0.04 to 0.35, $I^2=0.0\%$), and self-efficacy (ES=0.39, 95% CI=0.19 to 0.60, $I^2=0.0\%$) were also significant. There was no publication bias on Egger's test ($p=0.302$). **CONCLUSION:** Our findings suggest that exercise interventions can improve physical function and mobility in older adults after hip fracture. As exercise is a promising rehabilitation for this special population, future research is needed to establish best practices.

(No relevant relationships reported)

Nutritional misinformation may hinder healthy attitudes and impair athlete's performance. **PURPOSE:** To compare the frequency of right understanding and behaviour on nutritional related issues among male and female elite Brazilian athletes. **METHODS:** A total of 128 athletes, age 24.4±4.5 yrs, (61 males) who competed various modalities at international competitions participated in the study. The frequency of right answers (based on scientific literature) and the odds ratios for the association with sex were calculated. **RESULTS:** The table shows the frequency of right answers by sex.

Questions	Female (%)	Male (%)	OR
Understanding questions			
Is it important to eat more calories on more intensive training days?	56.7	65.5	0.68
Is it important to adjust the calories intake on rest days?	77.6	75.4	1.13
Do proper dietary recommendations benefit the athlete?	53.7	45.9	1.36
Is it important to eat fruits and vegetables as a source of vitamins and minerals?	7.4	14.7	0.46
Are dairy products sources of calcium and vitamin D?	74.6	80.3	0.72
Is water sufficient to replace all that is lost in sweat?	8.9	3.2	2.90
Is it important to eat in the first 45-60 minutes after training?	32.8*	8.1	5.47
Behaviour Questions			
I increase carbohydrate consumption before competitions	30.3	41.6	0.60
I try to consume a lot of protein regardless of origin	48.4	49.1	0.97
I have protein supplements prescriptions by qualified professionals.	59.7	70	0.63
I Take sports drink	70.1	77	0.70

*p<0,05 (female% >male%), OD = odds ratios

The only significant sex difference was the higher misunderstanding of males regarding the attitude towards the importance of eating after training. Depending on the questions, there was a large range in the % of adequate answers. **CONCLUSION:** A screening questionnaire, as used in the present study, may therefore guide to identify some specific aspects that deserve more focus in an educational intervention.

(No relevant relationships reported)

Optimal nutrition is essential for athletes to maximise performance. Food frequency questionnaires (FFQs) are commonly used to assess habitual dietary intake as they are inexpensive, quick and easy to administer.

PURPOSE: To determine the relative validity and reproducibility of an athlete-specific FFQ for assessing food group intake in high performing athletes.

METHODS: Athletes (n=66), 16-35 years, from several sports competing at regional level or above completed a 129-item FFQ at baseline (FFQ1) and four weeks later (FFQ2) to assess reproducibility. An estimated 4DFR was completed between these assessments to determine FFQ1 validity. Agreement between methods was assessed using Wilcoxon signed rank tests, Spearman correlation coefficients, cross-classification and the weighted kappa statistic.

RESULTS: The FFQ overestimated intake for 17 of 28 food groups compared with the 4DFR (p<0.05). Correlations ranged from 0.11 (processed meats) to 0.78 (tea, coffee & hot chocolate), with a mean of 0.41. Correct classification of food groups into the same tertile ranged from 35.4% (starchy vegetables) to 55.5% (fats & oils). Misclassification into the opposite tertile ranged from 4.6% (legumes) to 15.4% (starchy vegetables; sauces & condiments). The weighted kappa demonstrated fair to moderate (k =0.21-0.60) agreement for most food groups. FFQ1 intake was significantly higher than from FFQ2 for 13 food groups (p<0.05). Reproducibility correlations ranged from 0.49 (potato chips; fats & oils) to 1.00 (tea, coffee & hot chocolate), with a mean of 0.65. Using tertiles, most (20 of 23 assessed) food groups had >50% of participants correctly classified and <10% grossly misclassified, and demonstrated moderate to good agreement (k=0.61-0.8).

CONCLUSIONS: The FFQ showed reasonable relative validity and good reproducibility for assessing food group intake in high performance athletes in New Zealand. The FFQ could be used in future research to assess athletes' food group intake.

Macronutrient Intake And Blood Markers Concentrations In Mexican University Athletes.**

Alma Melissa Rodriguez-Arellano, Sayra Nataly Muñoz-Rodríguez, Sergio Alejandro Copado-Aguila, Marisol Villegas-Balcazar, Alejandro Gaytan-Gonzalez, Juan Ricardo Lopez-Taylor. Universidad de Guadalajara, Guadalajara, Mexico.

(No relevant relationships reported)

PURPOSE: To analyze the association between the concentration of different blood markers and macronutrient intake by sex in university athletes.

METHODS: 242 (139 males, 103 females) athletes of different sports were evaluated on their food habits. We administered 24-hour dietary recalls of a training day by standardized staff. Then, we estimated the absolute (g/day) and relative (g/kg/day) macronutrient intake. Also, we obtained uric acid, urea, creatinine, cholesterol, triacylglycerides, glucose, hemoglobin, and hematocrit concentrations from blood analysis. We only analyzed the data of subjects who had their blood samples and dietary recall within a period of no more than 30 days apart. The analysis was divided by sex.

RESULTS: Subjects' age, body weight, and height were: 21.4 ±3.0 and 20.7 ±2.0 years, 73.6 ±14.1 and 61.7 ±11.6 kg; and 175.8 ±6.8 and 163.6 ±6.9 cm, for men and women respectively. For males, there were significant associations between relative (beta [95% CI], -0.328 [-0.037 to -0.619]; p = 0.027) and absolute (-0.005 [-0.001 to -0.009]; p = 0.027) protein intake and uric acid concentrations; similarly, absolute protein intake was significantly associated with lower creatinine concentrations (-0.014 [-0.001 to -0.027]; p = 0.031). For females, there was a significant association between relative carbohydrate intake and blood glucose (1.912 [0.259 to 3.566]; p = 0.024). No other significant association was found.

CONCLUSIONS: In this study, protein intake was associated with lower blood creatinine and uric acid concentrations in males, and carbohydrate intake with higher blood glucose concentrations in females.

Food Provision For Athletes At The Olympic Games: Current Challenges And Future Directions**

Fiona E. Pelly, Judy Tweedie. University of the Sunshine Coast, Queensland, Australia. (Sponsor: Professor Melinda Manore, FACSM)

Email: fpelly@usc.edu.au

(No relevant relationships reported)

Providing appropriate food for athletes at the Olympic Games is a significant undertaking for organizing committees and caterers, particularly with increasing demands by teams for individualized dietary requirements, and consideration of global issues such as sustainability. Despite evidence that teams want a culturally appropriate performance-based menu, there is significant variation in the delivery of food at each event. **PURPOSE:** The aim of this study was to explore the perceptions of key stakeholders on issues with appropriate food delivery at major competitions, and understand the barriers to an integrated approach to nutrition servicing.

METHODS: Using an exploratory case study design, 12 stakeholders (event organizers, catering management, service staff, senior chefs, food safety auditor, and dietitians) with previous experience in catering at major competitions were interviewed

using a semi-structured question format. Interviews were audio-recorded, transcribed and thematically analyzed, then mapped to the foodservice system framework using a logic model as per case study reporting.

RESULTS: There were 7 major themes that emerged from the data. 1) consumers expectations of food provision are increasing; 2) the menu needs improvement in design and delivery but is limited by the catering system; 3) early planning and integration of the nutrition service in the food program is important; 4) previous experience and training of staff minimizes challenges; 5) there is greater demand to cater for food allergens and intolerances, which increases the risk to stakeholders; 6) food provision is segregated between the village and venues, which impacts the efficiency of the system; and, 7) better technology for labeling and communication of the menu is essential. Barriers were reported as organizing committees' viewpoints, limited budget for catering, local food environment, poor understanding of nutrition expertise, and segregation of food delivery. Mapping using a systems approach demonstrated that change is needed to the food vision and catering tender, due to the disconnect between high level policy and operation.

CONCLUSIONS: Development of a framework for provision of nutritionally adequate, culturally suitable and safe food will ensure consistency for future competition events.

2724 Board #185 May 29 9:30 AM - 11:00 AM

Association Between Carbohydrate Intake And The Dental Caries Presence In University Athletes

Sayra Nataly Muñoz-Rodriguez, Alejandro Gaytan-Gonzalez, Sergio Alejandro Copado-Aguila, Marisol Villegas-Balcazar, Juan Ricardo Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*

(No relevant relationships reported)

PURPOSE: To analyze the association between carbohydrate intake and consumption of sugar group servings with the presence of dental caries in college athletes.

METHODS: 159 (90 men, 69 women) college athletes from different sports were evaluated. 24-hour dietary recalls were administered to estimate the carbohydrate intake and the number of sugar servings consumed. In the same period, a dental evaluation was performed to determine oral health and possible dental injuries (specifically dental caries). Logistic regression analysis was performed to analyze the association between carbohydrate intake (g/day, g/kg/d, or categories as ≤3 g/kg/day, 3.1 to 5 g/kg/day, and > 5.0 g/kg/day), sugar group servings (sugar, honey, jam, jelly, sweet beverages) and the presence of dental caries.

RESULTS: 22 athletes (13.8%) presented dental caries. Carbohydrate intake was not significantly associated with dental caries when expressed in g/d (OR [95% CI], 1.00 [0.996 - 1.003]; p = 0.801), nor g/kg/d (0.992 [0.799 - 1.232]; p=0.943). The amount of sugar servings consumed was neither significantly associated with caries (1.010 [0.940 - 1.084]; p=0.793). In the analysis by carbohydrate categories (≤3 g/kg/day reference group) consuming 3.1 to 5 g/kg/day (0.779 [0.191 - 3.180]; p=0.728), neither >5.0 g/kg/day (1.3030 [0.487-3.484], p=0.598) were significantly associated with the presence of dental caries. Even after adjusting the model, there were no significant associations with carbohydrate and sugar servings with dental caries (Table 1).

CONCLUSIONS: Carbohydrate intake (expressed as g/d, g/kg/d, and categories) nor the number of sugar servings consumed were associated by themselves with the presence of dental caries. Further research is needed to elucidate if other non-dietary variables might modulate the association of carbohydrate intake and the presence of dental caries.

Table 1. Adjusted model analysis between carbohydrate intake and dental caries (n=159)

Model	Variables	OR	95% CI	p-value
1	Sugar servings	1.022	0.937 to 1.115	0.620
	CHO (g/d)	0.999	0.995 to 1.115	0.633
2	Sugar servings	1.014	0.935 to 1.100	0.736
	CHO (g/kg/d)	0.973	0.760 to 1.246	0.827
3	Sugar servings	1.012	0.937 to 1.093	0.760
	CHO (3.1 to 5 g/kg/d)	1.639	0.419 to 6.416	0.478
	CHO (>5 g/kg/d)	1.200	0.274 to 5.266	0.809

Adjusted model 3: ≤3 g/kg/day reference group.
CHO: Carbohydrates.

2725 Board #186 May 29 9:30 AM - 11:00 AM

Assessment Of Pre-season Body Composition, Meal Patterns, Food Choices And Preferences In NCAA Division 1 College Athletes

Jennifer Peluso, Takudzwa A. Madzima, Hanna Clay, Suzanne Hoskinson, Melissa Marazzi, Shefali Christopher, Srikanth Vallabhajosula, Svetlana Nepocatych. *Elon University, Elon, NC.* (Sponsor: Eric Hall, FACSM)

Email: jpeluso@elon.edu

(No relevant relationships reported)

The transition from high-school to college is typically associated with substantial changes in body composition, eating patterns, and food choices. **PURPOSE:** To assess pre-season body composition, eating patterns, food choices and preferences in Division I NCAA college athletes. **METHODS:** 118 incoming first-year athletes (males: n=69, BMI 25.5±5.5 kg/m2; females: n=49, BMI 22.3±2.7 kg/m2) from basketball, football, soccer, lacrosse, cross-country and tennis teams were recruited. Meal Patterns (MPQ), Food Preferences (FPQ) and Food Choices (FCQ) Questionnaires were used to assess eating patterns, factors that influence food choices and preferences. Body composition was assessed using dual energy x-ray absorptiometry (DXA) for lean body mass (LBM), fat mass (FM) and body fat % (BF%). A two-way ANOVA was used for analysis with significance accepted at p<0.05. **RESULTS:** Evening (86.2%) and lunch (66.1%) meals were the most frequently consumed meals followed by breakfast (52.5%) and evening snacks (21.2%). Nocturnal eating (eating during the night after having been to sleep) was the least common form of eating (31.4%). There was no significant difference observed in FPQ and FCQ between genders (p>0.05). However, a significant difference was observed in the importance of food for weight control (p=0.02), preference for vegetables (p=0.03) and starches (p=0.02) among sports. In addition, significant body composition differences were observed between males and females (FM: 13.4±10.9 kg and 17.0±7.3 kg, LBM: 67.5±9.0 kg and 44.8±5.3 kg, BF%: 14.8±8.4% and 26.7±7.3 %, p<0.001, respectively) and among sports (p<0.001). **CONCLUSIONS:** Certain eating patterns, such as skipping breakfast or lunch meals, may be detrimental to the maintenance of appropriate body composition in their sport. In addition, athletes in the endurance sports had higher preference for starches and based their food choices on the need to control weight.

2726 Board #187 May 29 9:30 AM - 11:00 AM

A Novel Tool For Understanding Factors That Can Influence The Food Choices Of High-performance Athletes.

Rachael Thurecht. *University of the Sunshine Coast, Sippy Downs, Australia.*

Email: Rachael.Thurecht@research.usc.edu.au

(No relevant relationships reported)

There are many facets that can influence the foods athletes choose and thus impact on achieving optimal nutrition, hydration, body composition goals and gut comfort. Despite this there are a limited number of studies exploring these determinants in athletes and no validated tool for understanding athlete food choices. **PURPOSE:** This research aimed to develop and validate an Athlete Food Choice Questionnaire (AFCQ) to determine the key factors influencing food choice in an international cohort of athletes. **METHODS:** A preliminary questionnaire containing 84 items on a 5-point frequency scale was developed and used to collect the first sample from athletes at the 2017 Universiade, Taiwan. Principal Component Analysis (PCA) was conducted on this sample to identify key factors and develop the AFCQ. A second sample was collected using the AFCQ at the 2018 Commonwealth Games, Australia. The second sample was analysed via Confirmatory Factor Analysis (CFA) to validate the factorial structure. Descriptive analysis of the combined samples was used to examine the AFCQ sensitivity in detecting differences in factor ratings between athlete cohorts. **RESULTS:** Sample one (n=156) contained athletes from 31 countries and 17 sports. The PCA extracted 36 questionnaire items organised into nine factors explaining 68.0% of variation. Sample two (n=232) contained athletes from 45 countries and 20 sports. The final model confirmed the nine constructs from the PCA, these were: 'nutritional attributes of the food', 'emotional influences', 'food and health awareness', 'influence of others', 'usual eating practices', 'weight control', 'food values and beliefs', 'sensory appeal' and 'performance'. The CFA resulted in a good model fit ($\chi^2=685.2$, $df=428$, $\chi^2/df=1.60$, $p < 0.01$) with the removal of four items, reducing the number of items to three per factor. The AFCQ was successful in distinguishing differences between factor ratings across demographic characteristics including gender, athlete caliber and sporting type. **CONCLUSION:** Simple enough to be utilised with athletes from a diverse range of sports, this new tool will enable researchers and sports dietitians to better tailor nutrition education and dietary interventions to suit the individual or team.

2727 Board #188 May 29 9:30 AM - 11:00 AM

Omega-3 Index Associated With Dietary Intake In NCAA Division 1 Collegiate Women Soccer Athletes

Aaron F. Carbuhn, Jackson Mores, Jeremiah Diaz, Linda D'Silva. *University of Kansas Medical Center, Kansas City, KS.*
Email: acarbuhn2@kumc.edu
(No relevant relationships reported)

Docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) omega-3 fatty acids are essential nutrients in supporting overall health. Omega-3 Index, a percentage of total fatty acids, is the sum of erythrocyte membrane DHA and EPA. This description of erythrocyte DHA+EPA is a standard measure of nutrient status. Previous research in NCAA Division 1 American football athletes (n=404) report mean Omega-3 Index was $4.4\% \pm 0.8\%$ suggesting an omega-3 deficient status. Dietary habits can influence omega-3 status. Food frequency questionnaires (FFQ) are often utilized to represent DHA and EPA intake habits from reported dietary recalls. Recently, in pregnant women, an abbreviated 7-question FFQ assessing DHA and EPA intake was correlated with Omega-3 Index. However, its potential utility in female athletes has not been explored. Also, Omega-3 Index is unknown in women collegiate athletes. **PURPOSE:** To measure Omega-3 Index and assess dietary DHA and EPA intake using an abbreviated 7-question FFQ on a NCAA Division 1 collegiate women's soccer team as well as investigate the association between respective measures. **METHODS:** 24 women soccer athletes, pre-season, completed abbreviated FFQ and provided Omega-3 Index blood collection sample. One drop of whole blood from a finger stick was collected by research group and analyzed by OmegaQuant Analytics, LLC (Sioux Falls, SD). Means and standard deviations were computed. Pearson correlations between Omega-3 Index and FFQ were determined. **RESULTS:** The mean Omega-3 index among all athletes was $4.3\% \pm 0.6\%$. Mean FFQ DHA and EPA intake was $84\text{mg/d} \pm 61\text{mg}$ and $49\text{mg/d} \pm 37\text{mg}$ respectively. The abbreviated FFQ was moderately correlated with Omega-3 Index ($r=0.487$, $p=0.016$). **CONCLUSIONS:** Division 1 women soccer athletes' Omega-3 Index are like previously reported American football athletes indicating a possible deficiency. Also, the abbreviated FFQ was correlated to Omega-3 Index suggesting it to be a possible predictor of omega-3 nutrient status in an athlete population. Lastly, these reported Omega-3 Index and FFQ findings in women soccer athletes suggest inadequate dietary intake of DHA and EPA to support overall health.

NUTRITION KNOWLEDGE AND SELF-REPORTED CONFIDENCE IN THAT KNOWLEDGE AMONG DIVISION II ATHLETES

Brian P. Reagan, Christa Parkes, Riggs Klika, FACSM, Nathan Eckert. *University of Indianapolis, Indianapolis, IN.* (Sponsor: Dr. Riggs Klika, FACSM)
(No relevant relationships reported)

NUTRITION KNOWLEDGE AND SELF-REPORTED CONFIDENCE IN THAT KNOWLEDGE AMONG DIVISION II ATHLETES.

Christa Parkes¹, Nathan Eckert¹, Riggs Klika¹, Brian Reagan¹ (Sponsor: Riggs Klika FACSM)¹

¹University of Indianapolis, Indianapolis, Indiana

Limited nutrition knowledge (NK) with high confidence is frequently reported among athletes. Overconfidence in false information increases poor nutrition behaviors and sharing of inaccurate nutrition information. **PURPOSE:** We hypothesized that NCAA Division II (DII) athletes will present limited NK (below 80% criterion) while reporting high confidence levels in four categories: (1) carbohydrates (CHO), (2) fats, (3) protein (PRO) and (4) weight management (WM). **METHODS:** All subjects signed informed consent and completed a modified Macronutrient and Energy Metabolism Survey (MEMS) via Qualtrics in a designated computer lab. Participants (N = 168) reported their confidence level based on their survey answers (39 total questions) using a Likert scale (1- 4): (1) not at all sure, (2) not sure, (3) somewhat sure, (4) very sure. Descriptive statistics were calculated with Spearman rank correlation coefficients between variables (e.g. correct vs. incorrect per category). **RESULTS:** Student athletes (n = 88 males, n = 80 females) completed the MEMS survey (return rate = 36%). Athletes lacked NK: mean score of 17/39 (43.5%) correct. The mean correct scores were 42% for fats, 41% for CHO, 41% for PRO, and 51% for WM. Also, a trend in overconfidence existed; for example individuals with incorrect responses for CHO, 65% felt at least (3) somewhat sure. Secondary analysis included a Spearman's rho correlation that resulted in a significant ($p = 0.05$) but weak negative correlation between response "correctness" and confidence level within each category: Fats ($r_s[1680] = -0.06$), CHO ($r_s[1680] = -0.2$), PRO ($r_s[1680] = -0.14$), and WM ($r_s[1512] = -0.23$). **CONCLUSION:** The results suggest that DII athletes lack NK and have relatively high confidence in misinformation. This study identifies an opportunity for intervention using Registered Dietitians to educate athletes about nutritional basics and raise awareness of respective misinformation.

Dietary Intake Patterns And Risk Of Energy Deficiency In Ncaa Endurance Athletes

Chris Hernandez¹, Michael Fredericson, FACSM², Aurelia Nattiv, FACSM², Emily Kraus², Andrea Kussman², Kristen Gravani², Beth Miller³, Lauren Papanos³, Megan Roche², Dylan Agans¹, Erik Grohmann¹, Catherine Brotman¹, Michelle Barrack¹. ¹California State University, Long Beach, Long Beach, CA. ²Stanford University, Stanford, CA. ³University of California, Los Angeles, Los Angeles, CA. (Sponsor: Dr. Aurelia Nattiv, FACSM)
Email: chernandez893@yahoo.com
(No relevant relationships reported)

PURPOSE: This study assessed dietary intake patterns among elite collegiate runners administered through a one-on-one counseling session with the team sports dietitian. **METHODS:** During the Fall sports seasons of 2015 to 2018, endurance runners from two NCAA Division I Cross-Country teams were asked to participate in a prospective study that focused on optimizing the health of the athletes. A 15 to 30-minute nutritional assessment involving the team sports dietitian was conducted. Runners in the current sample were non-injured. In the one-on-one nutrition counseling session, a standardized assessment evaluated the runner's dietary intake patterns and nutritional risks. Data was analyzed using chi-square and independent-samples t-tests. **RESULTS:** Final analyses yielded data from 158 male and female runners (47.1% male; 52.9% female), averaging 66.2 ± 2.1 (males) and 49.0 ± 9.4 (females) miles per week. A total of 23.4% of runners reported not eating for >4 hours on 4 or more days of the week, while 92.4% reported eating within 30 minutes upon completing exercise. Average meals/day and snacks/day among the sample were 2.9 ± 0.50 and 2.6 ± 1.1 , respectively. Females, compared to males, were more likely to report eating <3 meals per day (23.2% of females vs. 2.7% of males, $X^2 = 13.8$, $p < 0.001$), following a vegetarian or vegan diet (6.3% of females vs. 0% of males, $X^2 = 4.7$, $p = 0.03$), avoiding a food component or food group (31.6% of females vs. 11.0% of males, $X^2 = 9.6$, $p = 0.002$); Based on the one-on-one meeting/nutrition assessment, the sports RD noted higher proportion of female runners with an energy deficiency risk. (48.1% of female vs. 19.7% of males, $X^2 = 12.1$, $p < 0.001$). **CONCLUSIONS:** Most elite endurance runners reported eating a post-workout snack, which may aid in recovery efforts. As more females reported eating <3 meals per day it is recommended that females avoid skipping meals to reduce risk of energy deficiency and subsequent potential consequences to health and performance.

2730 Board #191 May 29 9:30 AM - 11:00 AM

Validation Of A Sports Nutrition Knowledge Questionnaire For Athletes In The United Kingdom And Ireland

Caitlin Edmonds¹, Ryan Tam¹, Sharon Madigan², Louise Gubb³, Kathryn Beck⁴, Janelle Gifford¹, Vicki Flood¹, Tania Prvan⁵, Luke Gemming¹, Helen O'Connor¹. ¹University of Sydney, Sydney, Australia. ²Sport Ireland Institute, Dublin, Ireland. ³St Mary's University, Twickenham, London, United Kingdom. ⁴Massey University, Auckland, New Zealand. ⁵Macquarie University, Sydney, Australia. (Sponsor: Melina M. Manore, FACSM)
Email: caitlin.edmonds@hotmail.com
(No relevant relationships reported)

PURPOSE: This study aimed to establish validity of an Australian/New Zealand developed sports nutrition knowledge questionnaire, Platform to Evaluate Athlete Knowledge in Sports-Nutrition Questionnaire (PEAKS-NQ) for use in United Kingdom and Irish (UK-I) athletes. **METHODS:** To confirm content validity, a convenience sample (n=16) of sports nutritionists (SN) from elite, UK-I sports institutes provided feedback on the PEAKS-NQ via a modified Delphi method. After minor changes, the UK-I version of the PEAKS-NQ (section A: demographics; sections B-F knowledge domains; max score 113 points) was administered via weblink to a convenience sample of UK-I SN recruited from the British Dietetic Association Senior Exercise and Nutrition Register, and elite athletes (EA) training at elite sports institutes in the UK-I. SN scores were the benchmark informing instrument construct validity. Cronbach's alpha (good ≥ 0.7) established internal consistency. Independent t-tests or non-parametric tests were conducted as appropriate. Results are reported as mean \pm SD, proportions and effect size (ES). **RESULTS:** SN achieved greater overall (SN (n=23): $92.3 \pm 9.3\%$ vs EA (n=154): $71.4 \pm 10.0\%$; ES: 2.1; $p < 0.0005$) and individual section scores ($p < 0.0005$) except section B ($p = 0.072$). Sub-section scores were as follows; Section B-Food groups (SN: $95.7 \pm 5.6\%$, EA: $91.5 \pm 7.8\%$), Section C-Nutrients (SN: $92.5 \pm 4.1\%$, EA: $76.3 \pm 9.5\%$), Section D-Applied Sports Nutrition (SN: $88.5 \pm 8.9\%$, EA: $56.7 \pm 14.5\%$), Section E-Competition Nutrition (SN: $88.6 \pm 5\%$, EA: $62.3 \pm 15.8\%$), Section F-Supplements and Sports Nutrition Concerns (SN: $92.3 \pm 9.3\%$, EA: $73.5 \pm 20.5\%$). Largest knowledge

differences between SN and EA were in section D. Sex, education level and sport type (endurance, high intensity/intermittent) did not independently influence EA total score. Instrument overall Cronbach's alpha (0.82) was good.

CONCLUSIONS: This study confirms content and construct validity of the PEAKS-NQ for assessing sports nutrition knowledge in UK-I athletes.

Development And Validation Of An Electronic Sports Nutrition Knowledge Questionnaire For Athletes
 Ryan Tam¹, Tanya Hamilton², Kathryn Beck³, Janelle Gifford¹, Tania Prvan⁴, Victoria Flood¹, Helen O'Connor¹. ¹The University of Sydney, Lidcombe, Australia. ²High Performance Sport New Zealand, Auckland, New Zealand. ³Massey University, Auckland, New Zealand. ⁴Macquarie University, Sydney, Australia.
 (Sponsor: Melinda Manore, FACSM)
 Email: rtam1827@uni.sydney.edu.au
 (No relevant relationships reported)

PURPOSE: Reliable assessment of sports nutrition knowledge (SNK) would help inform athlete nutrition education to address knowledge gaps. Electronic assessment is an accessible option able to provide immediate feedback. The aim of the study was to validate an electronic SNK assessment tool - Platform to Evaluate Athlete Knowledge of Sports Nutrition Questionnaire (PEAKS-NQ).

METHODS: PEAKS-NQ was informed by focus groups with sports nutritionists (n=16) from elite sports institutes in Australia and New Zealand (NZ) with content validity established via a modified Delphi Process. The PEAKS-NQ captured demographics (Section A) and assessed SNK across 5 domains (Sections B-F; max score 113 points). PEAKS-NQ was deployed to 92 developmental (junior) athletes (DA) in NZ, with a subset (n=50) invited to complete a re-test to evaluate reliability. To establish construct validity via the known groups method, 255 accredited sports dietitians (ASD) were invited to complete PEAKS-NQ. Score differences between DA and ASD were analysed using independent t or non-parametric tests. Reliability and internal consistency were evaluated using Sign Tests and Cronbach's α (good = ≥ 0.8) respectively. Results are reported as mean \pm SD.

RESULTS: DA (n=88) were 17.6 \pm 1.4y, 61.4% female, and mostly in high school (94.3%). ASD (n=45) were 37.8 \pm 7.6y, 82.2% female, with >5 years of dietetic experience (59.1%). ASD scored higher in all sections and overall (91.5 \pm 3.4%) compared to DA (67.1 \pm 10.5%) (p<0.001). Both DA and ASD scored best on Section B - Food groups (87.1 \pm 8.5 v 98.5 \pm 3.5%, p<0.001) and lowest on Section D - Applied Sports Nutrition (51.1 \pm 13.8 v 86.7 \pm 10.0%, p<0.001). In DA, there were no section or overall differences between re-tests (n=18; p=0.14). Overall Cronbach's α was good (0.86). Overall median completion time was 24 minutes.

CONCLUSIONS: PEAKS-NQ is a valid and reliable instrument for assessing SNK in athletes. A final stage of testing with more athletes will assist in establishing score ranges and factors influencing SNK.

Plasma Nutritional Markers From Brazilian Olympic Athletes
 Franz H p Burini, Roberto C. Burini, FACSM. *CeMENutri - UNESP Medical School, Botucatu, Brazil.* (Sponsor: Roberto Carlos Burini, FACSM)
 Email: f.burini@unesp.br
 (No relevant relationships reported)

Plasma Nutritional Markers from Brazilian Olympic Athletes
 Nutritional approach of athletes are still challenging in spite of progress on training issues. Training log and metabolic demands require specific strategies involving dietary pattern and supplementation, looking at clinical and injury issues. Nutrition biochemistry markers may guide specific approaches for optimizing health and enhance performance.

Purpose: The present study analyzed nutritional plasma biomarkers of Brazilian Olympic athletes at the moment they were called prior to the Olympic Summer Games - London 2012 and Rio 2016 (Judo, Boxing, Rowing, Canoeing, Synchronized Swimmers - 9 were medalists).

Methods: Fasting blood samples were taken from 69 athletes (21 males and 48 females; 23 \pm 7 years). The plasma was analyzed for Glucose (Glu), Insulin (Ins), Triglycerides (TG), Cholesterol (CT), HDL-c, LDL-c, Albumin (Alb), Osmolality (Osm) and Calcium (Ca). Whole blood was assayed for Haemoglobin (Hb) and used for Mean Corpuscular Volume (MCV) calculation. Values were expressed as Mean \pm standard deviation.

Results: Mean values were 67 \pm 9mg.dL⁻¹ (Glu - normal range: 70-100mg.dL⁻¹), 7.6 \pm 2.1mIU.L⁻¹ (Ins - 2-25mIU.L⁻¹), 84.7 \pm 17mg.dL⁻¹ (TG - <150mg.dL⁻¹); 173 \pm 13 mg.dL⁻¹ (CT - normal range: <200mg.dL⁻¹), 61 \pm 7 mg.dL⁻¹ (HDL-c - normal >40mg.dL⁻¹), and 94 \pm 2mg.dL⁻¹ (LDL-c - normal <130mg.dL⁻¹), Hb 14.4 \pm 3g.dL⁻¹ (normal range:

11.5-17.5g.dL⁻¹), MCV 87 \pm 6 fl (80-96fl); Alb 4.8 \pm 1.1g.dL⁻¹ (normal range: 3.5-5.5g.dL⁻¹) and Ca 9.8 \pm 2mg.dL⁻¹ (normal range: 8.5-10.2mg.dL⁻¹). Osmolality mean value was 293 \pm 52mmol.kg⁻¹ (normal range: 275-295mmol.kg⁻¹).

Conclusion: Besides all but glucose are within normal values, the haematological levels might be considered as target for some micronutrients supplementation. Similarly the found Osm would signal for additional hydration requirements. Nutritional requirements are specific due metabolic demand according to training log. Matching dietary pattern and supplementation aspects is challenging and should consider clinical as well as performance issues.

Association Of Adequate Carbohydrate And Protein Intake And Maximal Dynamic Strength In University Athletes

Karen Vanessa Vega-Garibay, Sayra Nataly Muñoz-Rodriguez, Eduardo Pinedo-Ruan, Sergio Alejandro Copado-Aguila, Alejandro Gaytan-Gonzalez, Juan Ricardo Lopez-Taylor. *Universidad de Guadalajara, Guadalajara, Mexico.*
 (No relevant relationships reported)

PURPOSE: To analyze the association between adequate carbohydrate and protein intake with the maximal dynamic strength in bench press and deadlift in university athletes.

METHODS: 30 male college (soccer and fast-soccer) athletes were evaluated. A 24-h dietary recall was administered to determine the macronutrient intake. Carbohydrate (CHO) and protein (PRO) intake were calculated and adjusted for body mass (g/kg/day). Consumption was classified as "adequate" if the athlete consumed the minimum amounts recommended for each macronutrient: 5 g/kg/day of CHO, 1.2 g/kg/day of PRO. Bench press and deadlift one repetition (1RM) tests were performed to determine the maximal dynamic strength. 1RM was adjusted for body mass (kg lifted/kg body mass). The association between macronutrient intake and 1RM was tested with linear regression. A sub-analysis was performed with the subject's categorization according to their CHO and PRO adequacy.

RESULTS: Neither g/d nor g/kg/d of CHO nor PRO were significantly associated with 1RM bench press nor deadlift. When participants were selected for their CHO (n=18) and PRO (n=29) adequacy there were no significant associations between CHO with 1RM of bench press (p = 0.763) and deadlift (p = 0.397). PRO showed the same pattern with no significant associations with bench press (p = 0.595) and deadlift (p = 0.912).

CONCLUSIONS: No association was observed between the adequate carbohydrate and protein intake with the 1RM of bench press and deadlift in university soccer players.

	Bench press		Deadlift	
	b (95% CI)	p-value	b (95% CI)	p-value
Protein (g/kg/d)	0.075 (-3.874 to 5.652)	0.704	0.023 (-7.154 to 8.036)	0.906
Protein (g/d)	0.145 (-0.430 to 0.920)	0.461	0.130 (-0.750 to 0.147)	0.511
Carbohydrate (g/kg/d)	0.176 (-1.438 to 3.731)	0.370	0.101 (-3.084 to 5.147)	0.611
Carbohydrate (g/d)	0.255 (-0.110 to 0.540)	0.191	0.233 (-0.220 to 0.086)	0.234

Iron Status And Perceived Fatigue And Recovery Across A Cross-country Season In Collegiate Runners
 Alyssa Christina, Kelly Pritchett, Robert Pritchett, Tafere Belay, Rande Marble. *Central Washington University, Ellensburg, WA.*
 Email: christinal@cwu.edu
 (No relevant relationships reported)

Iron depletion, with or without anemia, is of concern to endurance athletes given increased iron loss risk factors such as sweating, foot strike hemolysis, menstrual blood loss, and gastrointestinal bleeding. However, little is known regarding the impact of training volume on iron status, fatigue, and recovery in endurance athletes.
PURPOSE: To observe iron status and its subsequent effects on aerobic capacity and perceived fatigue and recovery in distance runners over a cross-country season.

METHODS: Male (n=10, age 19±1 yr, height 179±4 cm, weight 67±7 kg) and female (n=4, age 20±1.5 yr, height 164±6 cm, weight 57±3 kg) division II collegiate cross-country runners completed a complete blood count, ferritin level, maximal oxygen uptake test (VO_{2max}), and a three-day food record pre-season (August 2019) and post-season (November 2019). Survey data regarding average weekly mileage, fatigue (visual analog scale, 0-100 mm), and recovery (scale from 0, very poorly recovered - 10, very well recovered) were taken at baseline then monthly for a total of four assessments. **RESULTS:** Pre-season hemoglobin concentrations were 15.6±0.8 g/dl (males), 13.7±0.3 g/dl (females), and ferritin levels were 67.4±25.7 ng/ml (males), 56.8±44.4 ng/ml (females). Pre-season VO_{2max} was 64.1±2.4 ml·kg⁻¹·min⁻¹ for males and 52.6±2.9 ml·kg⁻¹·min⁻¹ for females. Weekly mileage remained similar across pre-season (51±17 mi), month 1 (56±7 mi), and month 2 (53±7 mi). Perceived fatigue increased significantly from pre-season (26±9 mm) to month one (59±15 mm) ($p < 0.001$), then decreased at month two (50±22 mm, $p = 0.23$). Perception of recovery decreased significantly from pre-season (7±1) to month one (5±2) ($p < 0.05$), then increased at month two (6±2, $p = 0.45$). Post-season iron status and VO_{2max} data will be evaluated following season completion. **CONCLUSIONS:** Relationships between iron status, VO_{2max} , and perceived fatigue and recovery will be assessed following completion of the competitive season.

Analysis Of Dietary Influence On Crossover Point In Combat Athletes And Runners

Joseph R. Stanzone, Rohit Ramadoss, Michael L. Bruneau, Jr, Stella L. Volpe, FACSM. *Drexel University, Philadelphia, PA.* (Sponsor: Stella L. Volpe, FACSM)
 Email: jrs484@drexel.edu
 (No relevant relationships reported)

Crossover point describes the moment during exercise that an athlete transitions from fat to carbohydrate for energy. There is limited research on sport specific differences, especially in Combat Athletes. Additionally, there is a need to understand the influence of diet on crossover point in an effort to optimize performance. **PURPOSE:** To evaluate if differences in crossover point exist between two sport types during a submaximal exercise test, and if an acute dietary intervention, 30 minutes before exercise, can influence crossover point. **METHODS:** Five male athletes (29.8 ± 6.3 years of age, 82.5 ± 8.9 kilograms, 174.7 ± 7.6 centimeters) were measured for respiratory exchange ratio during a submaximal exercise treadmill test under a fasted (FAST) condition, a fat-fed condition (FAT), and a carbohydrate-fed condition (CHO). Descriptive statistics determined average time, heart rate and percentage of maximal oxygen consumption (VO_{2max}). We used a Mann Whitney U test to denote differences between Combat Athletes and Runners, and Friedman's test to denote differences across dietary conditions. **RESULTS:** Combat Athletes (n=3) and Runners (n=2) achieved crossover at 12:20 ± 02:55 minutes (min) and 23:30 min ± 00:42 seconds (sec), respectively, with no significant differences between sport types ($p > 0.05$). All athletes achieved crossover at 16:48 ± 6:28 min, 59.5 ± 27.6% VO_{2max} at a heart rate of 124±19.5 beats per minute (bpm) during FAST. Under FAT, all athletes achieved crossover at 15:36 ± 5:53 min, 54.2 ± 17.7% VO_{2max} , and 122 ± 16 bpm. Under CHO, all athletes achieved crossover at 8:12 ± 02:27 min, 37.2 ± 13.5% VO_{2max} , and 95.6 ± 7.1 bpm. We found significant differences in time to crossover across dietary conditions ($p = 0.022$). **CONCLUSIONS:** Although we did not find differences in crossover points between sports, we did find differences among dietary conditions. It appears that CHO may dictate an earlier use of carbohydrate, while FAT did not increase reliance on fat. Future studies should seek to replicate our findings with a larger sample of athletes with parametric analyses to elucidate mechanisms of acute feeding on crossover differences across sport type. This study was not funded

Exercise And Diet On Muscle Strength And Body Composition In College Freshmen Composition In College Freshmen

Jinho Park, Vick Elias, Shannon Shen, Angelica Rodriguez, Jesse Delacruz, Roger Rodriguez, Joe Castillo, Sukho Lee. *Texas A&M University - San Antonio, San Antonio, TX.* (Sponsor: Minsoo kang, FACSM)
 Email: jpark@tamusa.edu
 (No relevant relationships reported)

Freshman often experience body changes upon entering college, but how do different exercise habits and diet patterns influence their physical outcomes? **PURPOSE:** To examine the differences in basic body characteristics and fitness levels based on exercise habits and diet pattern in college freshmen. **Methods:** The sample consisted of 103 college freshmen who completed measurements of body weight (BW), height, percent body fat (%BF), and physical fitness components including muscular strength (hand grip), flexibility, agility, and endurance. Exercise habits and diet patterns were surveyed. Total calorie consumption as well as carbohydrate, fat, and protein intakes were evaluated based on three-day dietary recall logs using computer software (Diet

Power, Inc., Danbury, CT). Participants were divided into exercise (EX; n=60) and no exercise (NE; n=43) groups based on current involvement of regular exercise. They were also categorized into eating less than two meals (LM; n=58) or three meals or more per day (TM; n=45). Descriptive results are expressed as means and standard deviation. Independent t-tests were used to compare group differences (EX vs. NE, LM vs. TM) on all variables. **Results:** Of the 103 participants, 27.4% were male and 72.6% were female. The participants in EX group (56.6%) had significantly higher muscular strength (29.17 ± 9.14 vs. 24.87 ± 6.14 (kg), $p = .007$) and lower %BF (31.59 ± 11.13 vs. 36.71 ± 10.34, $p = .017$) than participants in NE group. Interestingly, there was no significant difference in body weight between the two exercise groups. Participants in TM group (42.9%) had significantly higher muscular strength (30.51 ± 9.33 vs. 27.27 ± 7.07 (kg), $p < 0.05$) and height (1.66 ± 0.093 vs. 1.62 ± 0.079 (m), $p < 0.05$) than participants in LM group (57.1%). Participants in TM also had significantly higher total calorie consumption (4,005 ± 1,647.48 vs. 3,462 ± 1,091 (Kcal), $p < 0.05$), protein (703.56 ± 272.26 vs. 597.18 ± 261.75 (Kcal), $p < 0.05$), and fat intakes (1,579 ± 772.46 vs. 1,345 ± 496.02 (Kcal), $p < 0.05$) compared to the values in NM but not carbohydrate intake. **Conclusion:** This study shows that engaging in regular exercise is related to greater muscular strength and lower percent body fat, while consuming three meals per day is related to greater muscular strength and higher calorie intake in college freshmen.

2738 Board #199 May 29 9:30 AM - 11:00 AM
Examination Of Nutritional Intake Among University Marching Band Artists

Allison B. Smith¹, Toni Torres-McGehee¹, Nancey Uriegas¹, Cormack Cannon¹, Dawn Emerson². ¹University of South Carolina, Columbia, SC. ²University of Kansas, Lawrence, KS.
 (No relevant relationships reported)

Marching band (MB) artists (musicians and auxiliaries) have similar energy needs to those of athletes, based on the physical demands of performances. However, MB artists may lack knowledge of the recommendations for nutritional intake for active individuals. **Purpose:** To examine energy intake and Macronutrient (protein [PRO], carbohydrate [CHO], fats) intake compared to the nutritional recommendations in MB artists. **Methods:** We utilized data from a larger cross-sectional study. MB artists (n=37, Males: n=12, age: 19.8±1.4 years, height: 177.1±7.8 cm, weight: 74.6±23.8 kg; Females: n=25, age: 20.0±1.1 years, weight: 68.4±16.4 kg; height: 163.3±4.6 cm; from an NCAA Division I institution completed a survey (eg, basic demographics, band background, etc.) and were measured for height, weight, body composition, and resting metabolic rate (RMR). They participated in marching rehearsals for minimally 1.5 hours per day and completed a 7-day online dietary log to measure energy intake (EI). Basic descriptive statistics examined the proportion of participants who met nutritional recommendations. Independent samples t-test were used to compare between genders. Chi square were used to determine intake compared to recommendations. **Results:** MB artists demonstrated RMR and EI for males and females respectively; (2090.2±676.6 kcal, 1580.8±374.0 kcal) and (1531.0±460.7 kcal, 1258.0± 226.1 kcal). Significant differences were found when comparing gender and consumption of all macronutrients with Males consuming greater amounts than females; PRO: (94.7±39.1 g vs 60.3±23.2 g, $p = 0.002$), CHO: (249.7±80.4 g vs 193.7±73.1 g, $p = 0.042$), and fats: (80.9±32.3 g vs 57.7±16.4 g, $p = 0.006$). No significant differences were found between gender and nutritional recommendations for PROs, CHOs, and fats. However, 64.9% (n=24) and 94.6% (n=35) reported under consuming PROs and CHOs, while 43.2% (n=16) overconsumed fats. **Conclusion:** Overall, MB artist may be at risk for inadequate nutritional intake. With the physical demands associated with MB, it is recommended that MB artist be viewed as athletes. Therefore, healthcare professionals, such as athletic trainers, should provide resources and education on energy needs, proper fueling and adequate amounts of macronutrient intake.

Dietary Restrictions To Mitigate Gastrointestinal Symptoms In Runners

Robyn F. Madden¹, Kim Wagner-Jones², Kelly Anne Erdman³, Jill A. Parnell¹. ¹Mount Royal University, Calgary, AB, Canada. ²Helios Wellness Centres, Calgary, AB, Canada. ³Canadian Sport Institute, Calgary, AB, Canada.
 Email: rmadd656@mtroyal.ca
 (No relevant relationships reported)

Endurance runners frequently experience exercise-induced gastrointestinal symptoms, which can negatively impact their performance. As such, food choices pre-exercise have a significant impact on the gut's tolerance to running, yet little guidance is available. **PURPOSE:** Assess pre-race dietary intakes of runners to determine which foods and beverages are consumed and avoided and determine the most common gastrointestinal symptoms in runners who participate in races. **METHODS:** A questionnaire designed to assess dietary restrictions pre-race and gastrointestinal symptoms experienced during racing was administered to 388 runners (n=44% male). Fisher's exact tests determined differences in gender, age, performance level,

and distance with follow-up multivariable logistic regression modeling. **RESULTS:** Runners regularly avoided meat (32%), milk products (31%), seafood (28%), poultry (24%), and high-fiber foods (23%). Caffeinated beverages were commonly avoided in events 10 km or less ($p < .001$); whereas, in females, increased running distance was a predictor of avoiding high fiber foods ($OR = 6.7$; 95% $CI = 1.6-28.5$). Rates of food avoidance were elevated in younger and more competitive runners. Common gastrointestinal symptoms included stomach (42%), intestinal (23%), side ache/stitch (22%), urge to defecate (22%), and bloating (20%). The prevalence of gastrointestinal symptoms was higher in younger athletes, especially females, which may explain their propensity to avoid foods. Lower recreational athletes were the least likely to report gastrointestinal symptoms. Diarrhea increased with running distance. **CONCLUSIONS:** Identification of voluntary food restrictions in the pre-running meal highlights trends, which can be explored to develop dietary recommendations. Supported by the Mount Royal University Innovation Grant.

The Influence Of Macronutrient Intake And Body Composition On Biomarkers In Female Ballet Dancers

Alexa J. Chandler¹, Harry P. Cintineo¹, David J. Sanders², Bridget A. McFadden¹, Brittany N. Bozzini¹, Alan J. Walker³, Morgan S. Murray², Michelle A. Arent¹, Shawn M. Arent, FACSM¹. ¹University of South Carolina, Columbia, SC. ²Rutgers, The State University of New Jersey, New Brunswick, NJ. ³Lebanon Valley College, Annville, PA.
 Email: alexajc@email.sc.edu
 (No relevant relationships reported)

Low body fat percentage (%BF) and caloric intake may be associated with hormonal disruptions and adverse health effects in athletes. **PURPOSE:** The purpose of this study was to assess relationships between body composition (BC), dietary intake, and hormonal disruptions in female ballet dancers with self-reported oligomenorrhea. **METHODS:** Female ballet dancers ($N=7$; $M_{age} = 15.8 \pm 1.4$ y; $M_{BMI} = 18.8 \pm 1.5$ kg/m²) underwent BC testing to determine %BF and fat-free mass (FFM). Blood was drawn and analyzed for lipids (total cholesterol [TC], LDL, HDL, triglycerides [TG]), thyroid markers (thyroid-stimulating hormone [TSH], T₃, T₄), and adipokines (leptin [LEP], adiponectin [APN]). Five-day diet logs were recorded to determine energy (kcal) and macronutrient (CHO, PRO, fat) intake relative to body mass (kg). Pearson product correlations (r) were used to determine relationships between BC, biomarkers, and diet. Significance was set at $P < 0.05$. **RESULTS:** While BC did not significantly correlate with lipid markers, FFM correlated with T₃ ($r = -0.85$; $P < 0.05$), and the relationship with APN trended towards significance ($r = 0.93$; $P = 0.07$). Kcal/kg was positively correlated with TC ($r = 0.82$), and CHO/kg positively correlated with TG ($r = 0.91$) ($P < 0.05$). Correlations between CHO/kg and both LEP ($r = 0.83$) and APN ($r = -0.93$) approached significance ($P < 0.10$), while PRO/kg negatively correlated with TSH ($r = -0.91$; $P < 0.01$). Fat/kg correlated positively with TC ($r = 0.76$; $P < 0.05$), and correlations with LDL ($r = 0.59$) and T₄ ($r = -0.67$) approached significance ($P < 0.10$). **CONCLUSION:** Energy and macronutrient intake, rather than BC measures, appear to have greater associations to blood lipid levels, indicating dietary intake may play a larger role in augmenting lipid status and metabolism in this population. Additionally, increased PRO intake may play a unique role in overall metabolic status, suggested by the negative correlations with TSH. However, more research is needed to determine the influences of both energy intake and BC on menstrual status in this population. These findings warrant future investigations into dietary interventions designed to improve overall metabolism and health in ballerinas. Funding provided by Quest Diagnostics.

2741 Board #202 May 29 9:30 AM - 11:00 AM
Food Accessibility And Eating Patterns In Elite Collegiate Endurance Runners

Dylan Edwin Agans¹, Michelle Barrack¹, Michael Fredericson, FACSM², Emily Kraus², Andrea Kussman³, Kristen Gravani², Beth Miller³, Lauren Papanos³, Megan Roche², Chris Hernandez¹, Erik Grohmann¹, Catherine Brotman¹, Aurelia Nattiv, FACSM². ¹California State University, Long Beach, Long Beach, CA. ²Stanford University, Stanford, CA. ³University of California, Los Angeles, Los Angeles, CA. (Sponsor: Aurelia Nattiv, MD, FACSM, FACSM)
 Email: agans2114@gmail.com
 (No relevant relationships reported)

PURPOSE: This study aimed to evaluate factors relating to food accessibility and eating patterns among elite collegiate endurance runners. **METHODS:** From Fall 2015-2018, runners from two NCAA Division I Cross-Country teams were invited to participate in a study designed to optimize the health of endurance runners. All runners were non-injured and training regularly. The runners met with a team sports dietitian for a 15 to 30-minute counseling appointment. In these sessions, the dietitians conducted a standardized assessment to evaluate any outcomes relating to food

accessibility and eating patterns among collegiate endurance runners. **RESULTS:** The sample size involved 158 NCAA Division I collegiate athletes (47.1% male; 52.9% female). Runners reported training an average mileage of 66.2 ± 2.1 (males) and 49.0 ± 9.4 (females) miles per week. A total of 120 (79.5%) runners reported living in the dorms; 34.2% ($n=54$) reported no access to a kitchen; 3.8% ($n=6$) reported no access to a microwave or refrigerator; 2.5% ($n=4$) reported no access to a kitchen, microwave, or refrigerator. A higher proportion of runners without access to a kitchen reported eating < 3 meals per day (22.2% vs. 9.6% , $X^2 = 4.7$, $p = 0.03$). Runners living in the dorms ($n=120$) vs. those not living in the dorms ($n=31$) reported eating fewer meals per day, 2.9 ± 0.5 vs. 3.1 ± 0.5 , $p = 0.04$ and fewer snacks per day, 2.5 ± 1.1 vs. 2.9 ± 0.9 , $p = 0.05$. **CONCLUSIONS:** Collegiate runners living in the dorms and those without access to a kitchen reported consuming fewer meals and/or snacks per day. This may increase their risk of energy and nutrient deficits.

ASSOCIATION BETWEEN DIET, PERFORMANCE, AND HORMONAL CHANGES IN DIVISION I MALE SOCCER PLAYERS

Harry P. Cintineo¹, Bridget A. McFadden¹, Brittany N. Bozzini¹, Christopher E. Ordway², Alan J. Walker³, David J. Sanders², Marissa L. Bello⁴, Alexa J. Chandler¹, Shawn M. Arent, FACSM¹. ¹University of South Carolina, Columbia, SC. ²Rutgers University, New Brunswick, NJ. ³Lebanon Valley College, Annville, PA. ⁴Mississippi State University, Starkville, MS.
 Email: cintineo@email.sc.edu
 (No relevant relationships reported)

PURPOSE: The condensed preseason and match fixture in collegiate soccer impacts hormonal status, though the role of diet on this response is less studied. The purpose of this study was to assess athlete adherence to diet logs and determine relationships between diet and hormonal changes in collegiate soccer players. **METHODS:** Male collegiate soccer players ($N=22$) participated in preseason testing to assess body composition (%BF, FFM) and VO₂max. Energy expenditure (EEE) was measured during all on-field activities via heart rate monitoring. Blood draws were conducted during preseason and 45 d later for analysis of leptin (LEP), thyroid hormones (TSH, T₃, T₄), free cortisol (CORT), free testosterone (TEST), and IGF-1. Two 3-day diet logs were completed 21 d apart. Pearson product correlations and hierarchical regression were used to assess relationships between performance, diet, and biomarkers at $\alpha = 0.05$. **RESULTS:** Four (18.2%) participants completed all six days of diet logs. As such, individuals who completed ≥ 3 d were included in dietary analyses ($n=9$). %BF negatively correlated with Δ TSH ($r = -0.47$, $P = 0.04$). Protein intake correlated positively with FFM ($r = 0.75$, $P = 0.02$) and negatively with Δ LEP ($r = -0.74$, $P = 0.02$) and Δ TSH ($r = -0.74$). Moderate correlations were seen between Δ LEP and Δ IGF-1 ($r = 0.41$, $P = 0.04$) and Δ CORT and Δ TEST ($r = 0.41$, $P = 0.03$). When controlling for EEE, protein intake accounted for variance in Δ LEP ($R^2 = 0.51$; $P = 0.04$) and Δ TSH ($R^2 = 0.60$; $P = 0.02$), and FFM accounted for variance in TSH ($R^2 = 0.20$; $P = 0.06$). No relationships were found with VO₂max, T₃, T₄, and other measures. **CONCLUSIONS:** These findings show the limited utility of implementing diet logs in this population. The correlations between different hormones show the inherent associations between metabolic status, stress, and anabolism. Overall, the roles of body composition and protein intake on LEP and TSH, hormones associated with energy availability, suggests that protein may be a unique and understated factor in this equation. Funding provided by Quest Diagnostics

2743 Board #204 May 29 9:30 AM - 11:00 AM
An Investigation Of Dietary Patterns And Macronutrient Intakes Among Resistance-trained Men

Marta Kozior, Philip M. Jakeman, Robert W. Davies, Catherine Norton. University of Limerick, Limerick, Ireland. (Sponsor: Matthew P. Herring, FACSM)
 Email: marta.kozior@ul.ie
 (No relevant relationships reported)

PURPOSE: This study aimed to assess the adequacy of dietary patterns and macronutrient intakes in support of the adaptations to resistance training within a weekly microcycle of resistance-trained (RT) men using traditional dietary assessment methods. **METHODS:** Thirty-seven RT men (age (y) Mdn (IQR) 24.9 (20.7-29.7), body mass (kg) M (SD) 81.3 (11.8)) were recruited to participate in this study. Dietary data were collected by self-reported 7-day weighed intake record and analysed on both a daily and per eating occasion (EO) basis using nutrition software. Adequacy was assessed against recommendations for this population (ACSM, 2016; IOC, 2018). Data are reported as M (SD), Mdn (25-75 percentile) and p -value (p). **RESULTS:** Average daily energy intake for training day (TD) and rest day (RD) was 36 (7) and 34 (8) kcal·kg⁻¹·d⁻¹, respectively. Daily protein (PRO) intake (g·kg⁻¹·d⁻¹) was significantly greater than recommended minimum (1.6 g·kg⁻¹·d⁻¹) on TD (2.1 (0.5), $p < .001$) but was not different on RD (1.8 (0.6), $p = .050$). Carbohydrate (CHO) intake

(g·kg⁻¹·d⁻¹) was significantly lower than 5 g·kg⁻¹·d⁻¹ on both TD (3.6 (1.1), *p* < .001), and RD (3.3 (1.0), *p* < .001). Daily frequency of EO was significantly higher than the recommended 3-4 EO (*p* < .001) for TD (4 (3-6)) and RD (5 (4-5)). When analysed per EO (g·kg⁻¹·EO⁻¹), average PRO intake was significantly greater per main meal (MM) on TD (0.5 (0.4-0.7), *p* < .001) and RD (0.5 (0.4-0.6), *p* < .001), but not significantly different per snack (SN) (0.2 (0.1-0.3)) for TD (*p* = .126) and RD (*p* = .185) vs recommended 0.25 g·kg⁻¹·EO⁻¹. CHO intake (g·kg⁻¹·EO⁻¹) per MM was 0.9 (0.7 - 1.1) for TD and 1.0 (0.7-1.1) for RD. CHO (g·kg⁻¹·EO⁻¹) consumed per SN was 0.2 (0.1 - 0.3) for both TD and RD. Daily number of MM was 3 (3, 3) for TD and RD, and of SN were 3 (2-4) for TD, (1-3) for RD.

CONCLUSION: RT men met dietary recommendations to optimise adaptation to resistance training. However, the traditional dietary assessment methods do not address the importance of quantity, quality (source), timing, distribution and frequency of nutrients relative to a specific training session, termed peri-training nutrition (PTN), to optimise training adaptation. Future work must work towards analysis methods in support of periodised, personalised nutrition, relative to a specific training stimulus. FHI Grant TC20130001.

Nutritional Food Containing Inulin And Lactulose Reduces Bone Resorption Marker In Japanese Female Athletes

Tatsuya Ishizu¹, Eri Takai¹, Suguru Torii¹, Rie Ishizawa², Hiroko Murata³, Mizuki Kato¹, Motoko Taguchi¹. ¹Waseda university, Saitama, Japan. ²University of Texas Southwestern Medical Center, Dallas, TX. ³Jumonji university, Saitama, Japan.
 Email: t.ishizu@toki.waseda.jp
 (No relevant relationships reported)

Non-digestible oligosaccharides (NDOs) such as inulin and lactulose are regarded as the most beneficial prebiotics for improving bone health owing to their balancing effect on the gut microbiota. As many Japanese female athletes have issues related to bone health, a better understanding of the bioactivity of NDOs is vital.

PURPOSE: To determine the effect of nutritional food containing inulin and lactulose on bone turnover markers in Japanese female athletes.

METHODS: A total of 29 Japanese female athletes (age, 22 ± 1 years) were included. Participants took their regular meals with one pack of nutritional food per day, for 12 weeks. One pack of nutritional food provided 100 kcal of energy, 2.5 g of inulin, 1.0 g of lactulose, 100 mg of calcium, and 0.5 µg of vitamin D. Nutritional and exercise status were assessed at baseline, mid-intervention period, and 12 weeks later. Nutritional status was investigated using weighed food records, while exercise status was measured by using an accelerometer. Fecal samples were collected at baseline, 1, 2, 3, 4, 8, and 12 weeks for gut microbiota analysis. TRACP-5b, a bone resorption marker, and bone-specific alkaline phosphatase (BAP), a bone formation marker, were assessed at baseline, 4, 8, and 12 weeks. Body composition and bone status were measured using dual energy X-ray absorptiometry (DXA) at baseline and 12 weeks later.

RESULTS: The body composition, nutritional status, and exercise status of the participants did not change significantly during the intervention period. The occupation ratios of *Bifidobacterium* spp. increased at 3, 4 and 12 weeks (18.0 ± 8.3%, 17.6 ± 8.5% and 17.1 ± 7.6%, respectively) compared to that at the baseline (11.7 ± 7.3%) (*p* = 0.019, *p* = 0.035, and *p* = 0.073, respectively). Serum TRACP-5b was significantly decreased at 12 weeks (363 ± 112 mU/dL) compared to that at the baseline (430 ± 154 mU/dL) (*p* = 0.018).

CONCLUSIONS: These results suggest that intake of nutritional food containing inulin and lactulose over 12 weeks could help to reduce bone resorption marker in Japanese female athletes.

2745 Board #206 May 29 9:30 AM - 11:00 AM
Implications Of Protein Consumption On Quadriceps' Muscle Fiber Atrophy After Anterior Cruciate Ligament Tear

Rebecca Wang, University of Kentucky, Lexington, KY.
 (No relevant relationships reported)

There are well documented deficits in muscle mass and strength following anterior cruciate ligament (ACL) injury and reconstruction. Many factors influence recovery and progression of these deficits after ACL reconstruction such as pre-operative strength, rehabilitation quality and psychological factors. Overall energy and protein requirements increase after injury; however, little is known about the impact of nutrition following ACL injury. As protein is critical for repairing damaged tissues and promoting muscle anabolism, optimizing intake could help minimize loss of mass and strength following a sports injury. **PURPOSE:** To examine the role of pre-operative nutrition following an ACL injury and its potential relationship to quadriceps' muscle fiber atrophy. **METHODS:** 7 subjects with an ACL tear in the past 8 weeks (4M, 23.86 ± 5.79 y, BMI 24.24 ± 3.29) completed self-reported food records (6.6 ± 5.1 days pre surgery) over 3 non-consecutive days, including 1 weekend day. Subjects were given

written and verbal directions on how to log food in the *MyNetDiary* app. Nutrient reports were then extracted from food records using The Food Processor ® version 11.6.522 (ESHA Research, Salem, Oregon). Daily protein intake (g/kg of BW) was averaged across all 3 days. Biopsies were taken from injured and uninjured vastus lateralis (22.9 ± 10.7 days post-injury) to determine mean fiber cross-sectional area (CSA) between the injured and un-injured limb for each subject. Data are compared with a paired t-test or Pearson Correlation. **RESULTS:** Uninjured limb mean CSA was 4483 ± 380 µm²; injured limb mean CSA was 3816 ± 671 µm². The difference in CSA between limbs was significant (15% ± 16%, *p* = 0.03). Mean protein consumed among subjects 0.86 ± 0.23 g/kg per day, above the Recommended Dietary Allowance (RDA; 0.8 g/kg). There was a positive, non-significant correlation between atrophy and mean daily protein consumption per kg body weight (*p* = 0.23). **CONCLUSIONS:** These results serve as preliminary evidence to support the consumption of protein at the RDA may be insufficient given the substantial degree of muscle fiber atrophy occurring following an ACL tear. There is a need to optimize nutritional support during rehabilitation and our data suggest that protein consumption may be a therapeutic target to improve rehabilitation outcomes.

2746 Board #207 May 29 9:30 AM - 11:00 AM
A Comparison Of Body Image Perception And Weight Management In Latino And White Adolescent Soccer Players

Lynn Cialdella-Kam¹, Megan Patton-Lopez², Melinda M. Manore, FACSM³, Jane C. Carsey¹, Yu Meng⁴, Siew Sun Wong³. ¹Case Western Reserve University, Cleveland, OH. ²Western Oregon University, Monmouth, OR. ³Oregon State University, Corvallis, OR. ⁴University of California Agriculture and Natural Resources, Holtville, CA. (Sponsor: Melinda Manore, FACSM)
 Email: lak99@case.edu
 (No relevant relationships reported)

Weight-related behaviors and perception during adolescence can influence life-long weight management habits. Among the general population, difference in behaviors and beliefs have been observed by race/ethnicity and sex, but research is limited in athletes. **PURPOSE:** Determine if weight-related behaviors and perceptions differ by sex, race/ethnicity, and socioeconomic status (SES) in adolescent soccer players. **METHODS:** Adolescent soccer players (n=493, 56% Female, 45% Latino) completed a health history survey that included questions related to weight-related behaviors and perception. Body Mass Index (BMI, kg/m²) was determined from measured height and weight. **RESULTS:** Self-reported behaviors (trying to gain/lose weight or not change weight) differed by sex and by race/ethnicity (*p* < 0.05). Males were 10.2 times more likely to desire weight gain than females. Latinos were more likely to desire to lose weight vs. Whites. Weight-status perception varied by sex (*p* = 0.03); more males self-reporting being "underweight" than other categories. No race/ethnicity differences were observed (*p* > 0.05). Weight loss strategies differed by race/ethnicity (*p* < 0.0001) with Latinos reporting using exercise and drinking more water for weight loss. Adolescents desiring weight loss (38.7%) were 2.4 times more likely to skip breakfast or lunch. **CONCLUSIONS:** Future research should focus on understanding factors related to race/ethnicity and sex that influence weight-related attitudes/behaviors.

2747 Board #208 May 29 9:30 AM - 11:00 AM
Effects Of 8-Weeks Of Blueback-fish Consumption On Gut Microbiota In Elite Japanese Nordic Combined Athletes

Aya Ishibashi¹, Takanori Kono², Akiko Kamei¹, Yusuke Ishige¹. ¹Japan Institute of Sports Science, Kita-Ku, Japan. ²Ski Association of Japan, Shibuya-ku, Japan.
 (No relevant relationships reported)

PURPOSE: It is important for athletes in winter sports to maintain good conditions for performance during overseas expedition. Recently, differences in gut microbiota among athletes have been reported related to inflammation and performance. Omega-3 polyunsaturated fatty acid (PUFA) potential action in restoring eubiosis in gut microbiota (Costantini et al. 2017). On the other hands, n-3 PUFA deficiency induces a state of gut dysbiosis through alteration of gut microbiota composition (Robertson et al. 2017). However, in the athletes, the chronic effect of n-3 PUFA (blueback-fish)-riched foods intake on the gut microbiota is remains unclear. The present study investigated whether 8-weeks dietary n-3 PUFA enhances gut microbiota in athletes. **METHODS:** Six male (27 ± 6 yrs) elite Japanese Nordic combined athletes consumed processed foods containing blue-backed fish [800 mg eicosapentaenoic acid (EPA), 1300 mg docosahexaenoic acid/time] 4-5 times a week and continued for 8-weeks. Before and after the intervention, blood variables and gut microbiota, dietary surveys were evaluated. The gut microbiota was measured by Illumina sequencing of the bacterial 16S rRNA gene.

RESULTS: As a result of the dietary survey, there was no significant change in the energy intake and the intake of fish before and after the intervention except food of intervention. Resting concentrations of serum EPA (49 ± 18µg/mL vs. 108 ± 38 µg/

mL, $p = 0.01$) and EPA/AA ratio (0.26 ± 0.1 vs. 0.68 ± 0.3 , $p = 0.01$) were significantly elevated in after intervention. In gut microbiota, in after intervention decreased the indicator related to obesity and inflammation *Firmicutes/Bacteroidetes* ratio and significantly increased proportion of *Bifidobacteria* which lipopolysaccharide-suppressing bacteria ($2.4 \pm 2.1\%$ vs. $6.7 \pm 5.4\%$, $p = 0.046$).

CONCLUSIONS: A 8-weeks consumption of processed foods containing blueback-fish increased blood n-3 PUFA concentration and the presence of health-related taxa in gut microbiota. It may be possible the positive impact on gut microbiota in Japanese Nordic combined athletes.

Effect Of The Menstrual Cycle And Regular Workout On Oxidative Stress In Collegiate Female Students
 Harumi Hayashida. *Toin University of Yokohama, Yokohama, Japan.*
 Email: h-hayashida@fuji.waseda.jp
 (No relevant relationships reported)

Physical exercise is well known to impose oxidative stress due to the generation of reactive oxygen species. Additionally, in eumenorrhic women, oxidative stress may also be affected because the secretion of female hormones, which have antioxidant effects, varies during the menstrual cycle. The collegiate female athletes might have different oxidative stress at rest than normal women, due to both the increase in reactive oxygen species from daily training and changes in female hormones during the menstrual cycle. **PURPOSE:** To examine the influence of the menstrual cycle on oxidative stress levels at rest in collegiate female athletes and sedentary students. **METHODS:** Blood sample were taken from eleven female athletes and nine sedentary female students at four points during the menstrual cycle: menstrual phase (day 2.9 ± 0.9), follicular phase (day 9.0 ± 1.1), early luteal phase (day 15.9 ± 1.0) and late luteal phase (day 22.6 ± 0.9). Female athletes had done at least five three-hour regular workouts per week for over three years. All participants have a regular menstrual cycle and have never taken oral contraceptives. We measured plasma reactive oxygen metabolites (Reactive Oxygen Metabolites-derived compounds: d-ROMs) and antioxidant capacity (Biological Antioxidant Potential: BAP). **RESULTS:** The d-ROMs was significantly lower in the female athletes than the sedentary students (female athletes: 262.1 ± 27.8 U.CARR vs. sedentary students: 276.3 ± 36.4 U.CARR, $p < 0.05$). The d-ROMs slightly increased at the menstrual phase in sedentary students but it was not significantly altered by the menstrual cycle. The BAP was similar in both groups (female athletes: 2111.8 ± 132.6 $\mu\text{mol/L}$ vs. sedentary students: 2151.6 ± 212.6 $\mu\text{mol/L}$, NS) and unaffected by the menstrual cycle. **CONCLUSION:** Resting oxidative stress was lower in female athletes who regularly workout than in sedentary students, and it was not affected by the menstrual cycle. Interestingly, there was no difference in antioxidant capacity between them. These findings indicate that regular workout reduce the oxidative stress levels at rest in collegiate female athletes. However, the regular menstrual cycle had no effect on oxidative stress levels at rest in both athletic and sedentary female collegiate students.

Clinically-diagnosed Vitamin And Mineral Deficiencies And Disorders In The United States Military
 Joseph J. Knapik, FACSM, Emily K. Farina, Victor L. Fulgoni, III, Harris R. Lieberman. *US Army Research Institute of Environmental Medicine, Natick, MA.*
 Email: joseph.j.knapik.ctr@mail.mil
 (No relevant relationships reported)

No previous study has used medical records to assess the incidence of vitamin and mineral deficiencies in any civilian or military population. **Purpose:** This investigation examined incidence rates, temporal trends, and demographic factors associated with vitamin and mineral deficiencies/disorders in the entire United States military population from 1997 to 2015 (mean N = 1,382,266/year). **Methods:** A retrospective cohort design was employed. The Defense Medical Epidemiological Database and specific International Classification of Diseases, Ninth Revision, codes were used to determine incidence rates for clinically-diagnosed vitamin and mineral deficiencies/disorders. Associations with demographic factors were examined. Cases were selected only if the deficiency/disorder was the primary diagnosis. **Results:** The highest rates of vitamin and mineral deficiencies/disorders were for iron (104.3 cases/100,000 person-years [p-y]), vitamin D (53.7 cases/100,000 p-y), iodine (36.2 cases/100,000 p-y), other B-complex vitamins (20.2 cases/100,000 p-y), vitamin B₁₂ anemia (7.6 cases/100,000 p-y), deficiencies of "other vitamins" (5.9 cases/100,000 p-y), and vitamin A (2.5 cases/100,000 p-y). Thiamin, riboflavin, niacin, pyridoxine, folate, vitamin C, and vitamin K deficiencies and hypervitaminoses A and D had <1 case/100,000 p-y. Incidence rates for vitamin D, other B-complex deficiency,

"other vitamin" deficiency, thiamin deficiency, iron, and iodine increased over time (1997-2015), while vitamin A and C deficiencies decreased. Women had higher incidence rates for all examined deficiencies/disorders except niacin and vitamin C, especially for iron which was 12-fold higher. Incidence rates rose with age in 10 of 18 deficiency/disorder categories and blacks had higher incidence rates in 13 of 18 deficiency/disorder categories. **Conclusions:** Clinically-diagnosed vitamin and mineral deficiencies/disorders in the military population were low, but higher in women and minorities. As for most illnesses, the diagnosed incidence of such disorders may be an underestimate of the actual incidence. These findings can be used to guide clinical decision making with regard to testing for nutritional deficiencies and delivering public health information to at risk military and civilian populations.

2751 Board #212 May 29 9:30 AM - 11:00 AM
Vitamin And Mineral Intake Relative To The DRIs In Young Adults
 Samantha M. Coogan, MS, RDN, CSSD, LD, FAND, Laura J. Kruskall, PhD, RDN, CSSD, LD, FAND, FACSM, John C. Young, PhD, FACSM. *University of Nevada, Las Vegas, Las Vegas, NV.* (Sponsor: John C. Young, PhD, FACSM)
 Email: samantha.coogan@unlv.edu
 (No relevant relationships reported)

Food choices by college-age students are influenced by budgetary constraints, convenience, and irregular eating patterns which together may negatively affect micronutrient intake. NHANES groups adults from age 19-60 which may misrepresent the subset of young adults. **PURPOSE:** To evaluate the eating pattern of young adults in relation to micronutrient intake and the DRI. **METHODS:** Three-day nutrient intake reports were collected from male (n=379) and female (n=627) students, ages 18-21, enrolled in an introductory nutrition course, and entered into nutrition assessment software. Micronutrients reported included: vitamins A, thiamin, riboflavin, niacin, B6, B12, C, D, E, & folate, and Ca, Fe, Mg, P, K, Na & Zn. **RESULTS:** Both males and females met or exceeded DRI for thiamin, riboflavin, niacin, B6, B12, C, but were $\leq 50\%$ of DRI for A, D, & E. Only Na intake exceeded DRI in females while intake of Ca, Fe, P, & Na exceeded DRI in males with iron intake being the largest male-female difference. **CONCLUSION:** Micronutrient intakes in this population confirm the self-reported food choices: low milk/dairy consumption and high consumption of meat products. Sodium and phosphorus intake was suggestive of high consumption of processed foods and soft drinks. Vitamin C intake is consistent with high consumption of citrus fruit and fruit smoothies. However, the consumption of fresh vegetables was lacking. Daily caloric intake was adequate for this population (males 9200 KJ; females 6700 KJ). While multivitamin use was not documented, nutrient intake based on food consumption was inadequate, suggesting a daily multivitamin may be appropriate.

2752 Board #213 May 29 9:30 AM - 11:00 AM Effect Of Creatine Supplementation On Muscle Oxygen Saturation

Morgan Vance. *Salisbury University, Salisbury, MD.*
 Email: mvance2@gulls.salisbury.edu
 (No relevant relationships reported)

Data have indicated that creatine supplementation can result in an increase in lower leg anterior compartment pressure at rest and post exercise. Although the increased pressures seen during these studies were not pathological, this and additional factors associated with creatine supplementation could possibly influence skeletal muscle oxygen concentration (SmO₂) during exercise and recovery. **PURPOSE:** To determine the effects of acute creatine monohydrate supplementation on SmO₂ during treadmill exercise. **METHODS:** 21 male, physically active participants were randomized in a double-blind fashion to placebo (PL) (n=10, 23±2 yrs.) or creatine (CM) (n=11, 21±2 yrs.) groups. Subjects received 0.3 g/kg/day creatine monohydrate or placebo in gelatin capsules for 7 days. The subjects performed submaximal exercise tests (10 minute treadmill activity at 3.7 mph and 9% incline) at baseline and on day 7 of the study. During exercise SmO₂ and lower leg pain (LP) were monitored utilizing near infrared spectroscopy and an analog visual scale, respectively. The % change in SmO₂ was defined as: ((Baseline SmO₂ - peak exercise SmO₂)/baseline SmO₂)*100. Pre- and post-exercise lower leg pain thresholds (PTH) were determined using a digital force gage. **RESULTS:** There was a significant group effect (P<0.03) but no significant effect of supplementation (P>0.05) on the % change in SmO₂ during the exercise tests (CM: pre 66.49 ± 30.54; post 59.61 ± 23.87 vs. PL: pre 39.87 ± 16.72; post 38.51 ± 26.95 % change SmO₂; M ± SD). No significant effects of supplementation were seen between the groups for PTH (P>0.05) or peak LP during exercise (P>0.05). **CONCLUSIONS:** Using a randomly controlled, double-blind trial with validated measurements of SmO₂, acute creatine supplementation does not appear to impact skeletal muscle oxygen saturation during exercise in young, otherwise healthy males.

2753 Board #214 May 29 9:30 AM - 11:00 AM Omega-3 Fatty Acid Supplementation With Resistance Exercise Improves Muscular Strength And Inflammation In Older Adults

Sang-Rok Lee, Rebecca P. Mehlin, Gilbert Sigala, Joshua K. Krause, Lexie P. Fitch, Josi R. Gabaldon, Neva L. Williams, Dean Directo, Carole A. Carson. *New Mexico State University, Las Cruces, NM.* (Sponsor: Joseph Berning, FACSM)
 Email: srlee@nmsu.edu
 (No relevant relationships reported)

Fish oil (FO) enriched with omega-3 polyunsaturated fatty acids has attracted great attention for their health-enhancing benefits; however, synergistic effects of FO supplementation combined with resistance training (RT) in muscular strength, inflammation, and antioxidant capacity in older adults are not well established. **PURPOSE:** To investigate the effects of 12-wk FO consumption with programmed RT on muscular strength and inflammatory and antioxidant biomarkers in older adults. **METHODS:** Twenty healthy older adults (62 - 77 years) were randomly assigned to the resistance training (RT; n=10) or RT combined with FO group (RTFO; n=10). The RTFO group consumed fish oil supplements enriched with n-3 polyunsaturated fatty acids [3 capsules per day - 2100 mg of eicosapentaenoic acid (EPA) and 720 mg of docosahexaenoic acid (DHA)] and performed progressive RT including lat pull-down, seated row, biceps curl, leg press, and calf raise (2 sets of 10 repetitions; 2x/week for 12 weeks). One repetition maximum (1RM) for muscular strength assessment and blood C-reactive protein (CRP) and catalase (CAT) were evaluated for inflammation and antioxidant capacity pre- and post-intervention. Data were analyzed using 2 × 2 (group × time) repeated-measures ANOVA. **RESULTS:** Muscle strength in all five muscle groups substantially increased in both groups with a greater extent in RTFO; lat pull-down (+12 vs. +21%), seated row (+25 vs. +46%), biceps curl (+26 vs. +36%), leg press (+24 vs. +55%), and calf raise (+32 vs. +45%) (p < 0.05). There was a significant decrease in CRP in RTFO (-6% p < 0.05), while no detectable change was observed in RT. There was no significant change in CAT for both groups (p > 0.05). **CONCLUSION:** Twelve-weeks of FO supplementation appears to enhance the benefits from programmed RT in muscular strength, while improving systemic inflammation in healthy older adults. Supported by New Mexico State University.

2754 Board #215 May 29 9:30 AM - 11:00 AM Effects Of Ammonium Salt Inhalation On Reaction Time And Resistance To Fatigue In Male Athletes

Joshua S. Aune, Mary C. Stenson. *College of Saint Benedict's Saint John's University, Collegeville, MN.*
 Email: jaune001@csbsju.edu
 (No relevant relationships reported)

Strong scents stimulate the central nervous system, potentially increasing reaction time. Ammonium salt inhalants have no known physiological effect, but there is evidence of positive psychological effects on performance. Many athletes believe ammonium salt inhalants provide an edge or a feeling of "wakefulness". **PURPOSE:** To analyze the effect of ammonium salt inhalants on reaction time, power, and resistance to fatigue in male collegiate athletes. **METHODS:** Ten male athletes (21 + 0.82 yrs, 178.33 + 6.97 cm, 85.12 + 15.57 kg) were familiarized with the testing procedures during session one. Two randomized treatment sessions (ammonium salt inhalants or control) were performed 48 hr apart. In session two, subjects inhaled one treatment before each of three trials of reaction time test and vertical jump (VJ). After running to fatigue on the Anaerobic Treadmill Test (ATT) subjects inhaled the substance, then resumed the test to exhaustion. In session three, the same procedures were followed with the opposite inhalant. **RESULTS:** Reaction time after inhaling ammonium salt (0.645 + 0.060 s) was not significantly different from reaction time after inhaling the control treatment (0.646 + 0.098 s; t(9) = 0.032; p = 0.975). VJ after inhaling ammonium salt (54.51 + 5.00 cm) was not significantly different after inhaling the control treatment (55.93 + 6.58 cm; t(9) = 1.038; p = 0.326). ATT run time increased after fatigue when inhaling ammonium salt (12.873 + 4.60 s), but not significantly compared to inhaling the control treatment (11.30 + 4.55s; t(9) = 1.29; p = 0.227). **CONCLUSION:** Ammonium salt inhalants did not significantly improve reaction time, VJ, or ATT run time after fatigue in male collegiate athletes. Ammonium salts may have greater efficacy for anaerobic exercise performance compared to power performance.

2755 Board #216 May 29 9:30 AM - 11:00 AM Abstract Withdrawn**2756 Board #217 May 29 9:30 AM - 11:00 AM 30 Days Of Montmorency Tart Cherry Supplementation Has No Effect On Inflammation, Sleep, Or Body Composition In Healthy Adult.**

Angela R. Hillman¹, Bryna C.R. Christmas². ¹*Ohio University, Athens, OH.* ²*Qatar University, Doha, Qatar.*
 Email: hillman@ohio.edu
 (No relevant relationships reported)

INTRO: Tart cherries possess antioxidant, anti-inflammatory and analgesic properties that may reduce inflammation and improve sleep. Additionally, animal models suggest tart cherry supplementation can reduce weight, however human data is lacking. Furthermore, processing may affect the properties of tart cherries and therefore reduce their health benefits.

PURPOSE: To investigate the effect of different tart cherry supplements on markers of inflammation, body mass, and sleep time and quality over the course of 30 days in healthy individuals.

METHODS: 58 participants (age: 28 ± 10 y, Height: 169.76 ± 8.55 cm, body mass: 72.2 ± 12.9 kg) were separated into four groups: group 1 (Montmorency tart cherry juice), group 2 (Montmorency tart cherry capsule), group 3 (juice placebo) and group 4 (capsule placebo), and asked to consume their supplement for 30 continuous days. Participants in groups 1 & 3 drank two 8 oz. bottles per day. Groups 2 & 4 consumed two capsules with breakfast. Participants completed four trials: baseline, day 7, day 14 and day 30. During each trial participants provided a blood sample (assessed for inflammatory markers), and had their body mass and body composition assessed via bioelectrical impedance. Participants tracked their sleep daily via an online survey that asked about length of sleep (hours) and subjective rating of sleep quality (100 mm VAS). Linear mixed models were used to examine changes in inflammatory markers, body mass and body fat between groups. Additionally, a random coefficient model was used to assess the change in total sleep, and sleep quality across time (i.e. 30 days), between group.

RESULTS: There was a significant increase in erythrocyte sedimentation rate (f = 14.7, p < 0.001) between baseline and day 7 (p < 0.001; 95% CI = 3.16 - 6.96), day 14 (p < 0.001; 95% CI = 3.14 - 5.94), and day 30 (p < 0.001; 95% CI = 3.21 - 6.57). There was no significant difference in body fat, or body mass (p ≥ 0.08). There was a significant positive association between sleep quality and time (f = 5.47, p = 0.02). On average, sleep quality increased by 0.38 mm every day. There was no association for total sleep time (p ≥ 0.15).

CONCLUSION: These data suggest tart cherry supplements do not significantly reduce inflammation or improve sleep time, body fat or body mass. However, subject sleep quality improved over 30 days.

Effectiveness Of Two Different Forms Of Marine Oil On Muscle Soreness Following Eccentric Exercise

Matthew J. Barenie, Jessica A. Freemas, Kadie L. Freeman, Marissa N. Baranaukas, Curtis S. Goss, Timothy D. Mickleborough. *Indiana University, Bloomington, IN.*
 Email: matbaren@iu.edu
 (No relevant relationships reported)

PURPOSE: We have previously shown¹ that four weeks of supplementation with PCSO-524®, a marine lipid fraction of the New Zealand green-lipped mussel (*Perna canaliculus*), rich in omega-3 fatty acids, attenuates muscle damage and delayed onset muscle soreness (DOMS) following eccentric exercise in untrained men. The present study sought to determine if a blend of 75% PCSO-524® and 25% krill oil (ESPO-572®) will be 'at least as good' as PCSO-524® in attenuating DOMS and functional indices of muscle damage during recovery from muscle damaging exercise in untrained men. **METHODS:** This study was conducted as a randomized, parallel group, double-blind non-inferiority trial. Fifty-one untrained men were randomly assigned to consume 600 mg·d⁻¹ (4 capsules) of either PCSO-524® (n=24) or ESPO-572® (n=27) for 26 d prior to muscle damaging exercise (downhill running), and continued for 72 h following exercise. DOMS, pressure pain threshold (PPT), limb swelling, knee extensor range of motion (ROM), and isometric torque (MVC), were assessed at baseline following supplementation before eccentric exercise, and at 24, 28 and 72 h post-eccentric exercise. For data analysis purposes we included placebo group (olive oil) (n=16) data generated from our previously published work¹ that followed an identical study design. **RESULTS:** ESPO-572® is 'at least as good' as PCSO-524®, but both blends were significantly better (p<0.05) than placebo, in reducing DOMS at 24, 48, 72 h following muscle damaging exercise. At 24 and 48 h following the eccentric exercise bout ESPO-572® significantly increased (p<0.05) ROM compared to PCSO-524®. Compared to placebo, ESPO-572® significantly improved (p<0.05) ROM at 24, 48 and 72 h, while PCSO-524® significantly increased (p<0.05) ROM at 48 and 72 h during recovery. There were no significant differences (p<0.05) between ESPO-572® and PCSO-524® for PPT, limb swelling and MVC during recovery from muscle damaging exercise. **CONCLUSION:** These data suggest that ESPO-572® may represent a useful therapeutic agent for attenuating muscle soreness following eccentric-type exercise in untrained men. ¹Mickleborough et al. *Journal of the International Society of Sports Nutrition* (2015) 12:10.  Email: blanca.ortega@uacj.mx
 (No relevant relationships reported)

Strenuous exercise (SE) is a trigger for oxidative stress (OxS) associated with severe tissue damage, fatigue and the development of chronic degenerative diseases. **PURPOSE:** To evaluate the antioxidant capacity (AOxC) of mango peel extract (MPE) on OxS associated with SE in rats. **METHODS:** An animal bioassay, approved by bioethics committee, which consisted in an acute SE session performed, or not, after a sub-chronic (1 month) supplementation was executed. The treatments applied were: A) Standard diet (CTRL); B) Standard diet + gallic acid (GA); C) Standard diet + MPE (SMPE). The plasma OxS markers were quantified by Malondialdehyde (MDA) and protein carbonyls (PC). Creatine kinase (CK) and transaminases (ALT & AST) were evaluated as tissue damage markers. Finally, the plasma AOxC was evaluated by ferric reducing antioxidant power (FRAP) assay. **RESULTS:** The bioassay results are depicted in **Table 1**. The SE raised PC but no MDA plasma concentrations, on all treatments, also increase CK and AST. Otherwise as response to SE, FRAP activity on plasma was boosted on GA and SMPE. Preliminary phytochemical analysis on MPE presented a total phenolic compound content of 77±3 mg Gallic Acid Eq·g⁻¹ dry weight and 11±0 mg Catechin Eq·g⁻¹ dry weight of total flavonoids. **CONCLUSION:** The MPE has a high concentration of phenolic compounds and its administration improves the plasma AOxC, but it was not able to inhibit the effects of tissue damage or OxS associated with SE. Also, there was found that MPE has a prooxidative effect by altering the levels of protein oxidation after SE.

D-ribose Supplementation On Delayed Onset Muscle Soreness After Plyometric Exercise In College Students: A Randomized Controlled Trial.

Junqiang Qiu¹, Wei Cao¹, Tianwei Cai¹, Longyan Yi¹, Dan Benardot, FACSM², Menghui Zou¹. ¹Beijing Sport University, Beijing, China. ²Emory University, Atlanta, GA.
 Email: qiuqj001@sina.com
 (No relevant relationships reported)

PURPOSE: This study was aimed to investigate the effect of D-ribose supplementation on delayed onset muscle soreness (DOMS) induced by plyometric exercise. **METHODS:** 21 male untrained college students (age 21±2 yr, weight 75.5±11.2 kg) performed a lower-limb plyometric exercise protocol (7 sets of 20 frog jumps with 90s-rest between each sets) to induce DOMS. Muscle soreness were measured with Visual Analogue Scale before and 24, 48 hours after exercise. Subjects were then randomly divided into the D-ribose group (RIB, n=11) and the placebo group (PLA, n=10) according to BMI and muscle soreness. After a 14-day washout period, both groups performed the same plyometric exercise protocol. The RIB ingested 200ml solution containing 15g D-ribose 1 hour before and 1, 12, 24, and 36 hours after exercise, while the PLA ingested 200 ml calorically equivalent solution containing Sorbitol and β-cyclodextrin. Muscle soreness were collected and isokinetic muscle strength tests were performed and venous blood was collected before and 24, 48 hours after exercise. **RESULTS:** In RIB, muscle soreness at 24h and 48h after the second exercise session were lower than those after the first exercise session (Fig 1). In the second exercise session, muscle soreness and some blood indicators including CK, LDH, MB and MDA in RIB were lower than those in PLA at 24h after exercise (MDH, p<.05; CK, LDH, MB, p<.01). At 48h after exercise, LDH (176.19±65.12 vs. 304.76±45.51 U/L) and MDA(3.76±1.18 vs. 6.89±1.42 U/m) in RIB were still significantly lower than that in PLA (p<.01). There was no difference in results of isokinetic muscle strength and some oxidative stress indicators including superoxide dismutase and total antioxidant capacity between the two groups 24h and 48h after exercise. **CONCLUSIONS:** D-ribose supplementation reduces muscle soreness and makes recovery of muscle damage and inhibit the formation of lipid peroxides after plyometric exercise.

Figure 1. Muscle soreness in different groups

Effects Of Alpha-gpc And Huperzine-a On Memory And Power Output Post Exhaustion

John P. isaacs, Michael Lane, Aaron Sciascia. *eastern kentucky university, richmond, KY.*
 Email: john_isaacs38@mymail.eku.edu
 (No relevant relationships reported)

Introduction: The use of multi-ingredient pre-workout supplements has been steadily on the rise in the fitness industries. Companies make claims about improvements in performance both physically and cognitively for users but seldom provide research to back up the claims made about the ingredients or dosages. **Purpose:** To examine the effects of Huperzine-A and Alpha-GPC on short term memory and anaerobic power output, post exhaustion compared to caffeine and placebo in healthy college age students. **Methods:** The study was conducted as a double blind, placebo controlled, randomized design on 62 healthy adults (N=62 height 68.4 ± 3.5 in., weight 78.5 ± 15.1 kg.). The wash out period was a minimum of 48 hours after completion of the familiarization. Subjects reported to the exercise physiology lab thirty minutes before testing began and consumed either a caffeine, Alpha-GPC and Hup-A, or placebo solution. After the thirty-minute digestion period subjects performed one computer-based short-term memory test, and a thirty-second Wingate anaerobic power test. Subjects then performed an exhaustion protocol before repeating the memory and power test. Once all testing was completed subjects returned between 2 and 14 days after the last test and repeat the protocol. A power analysis was run using G* Power software 3.1.9.2 based from Zeigenfuss et al., (2008). The percent change between pre and post was compared across visits using ANOVA with repeated measures. Significance was found with an Alpha level $P \leq 0.05$ with Tukey Post Hoc analysis will be used to determine pairwise comparisons. All stats were run on IBM SPSS 23. **Results:** The ANOVA with repeated measures and Tukey Post Hoc analysis found there was no significant difference in performance pre to post, between groups, or factoring the percent change pre to post. **Conclusion:** This result suggests there is no physical or mental benefit acutely dosing 600 mg. of Alpha-GPC and 200 mcg. of Huperzine-A in healthy recreationally active adults. This was the first study to look at the two in combination so, the finding is neither supported nor opposed to the current body of research. The finding does oppose the logic some supplement companies have been using to justify their sales tactics. Future research should investigate the effects of a loading period on physical and mental performance.

Nitrate And Nitrite Treatment Modulate Performance And Available Fuel Sources In Zebrafish Muscle And Liver

Rosa M. Keller, Laura M. Beaver, Patrick N. Reardon, Norman G. Hord. *Oregon State University, Corvallis, OR.*
 Email: rosamoonkeller@gmail.com
 (No relevant relationships reported)

Treatment with nitrate, but not nitrite, improves exercise performance, in part, by increasing availability of metabolic fuels that require less oxygen for energy production. However, the mechanisms by which these inorganic anions produce performance effects is not well understood. **PURPOSE:** The purpose of this study is to quantify changes in the metabolic state in zebrafish muscle and liver with nitrate and nitrite treatment during exercise using gene expression and metabolomic methods. **METHODS:** Liver and muscle were collected from adult zebrafish fish exposed to sodium nitrate (606.9 mg NaNO₃/L water), sodium nitrite (19.5 mg NaNO₂/L of water), or control water for 21 days (n= 128-130). Tissues were analyzed by quantitative real-time PCR and ¹H-NMR untargeted metabolomics. **RESULTS:** Nitrate treatment significantly increased expression of peroxisome proliferator activated receptor- γ (*pparg*), a gene involved in regulation of lipid and glucose metabolism. In contrast, acetyl-CoA carboxylase (*acaca*), a gene that inhibits fatty acid oxidation, significantly decreased in the skeletal muscle of fish treated with nitrate or nitrite as compared to control skeletal muscle tissue. Nitrite treatment also significantly increased carnitine palmitoyl transferase 1b (*cpt1b*) expression in the liver, which is a primary regulator involved in long-chain fatty acid transport into the mitochondria. Preliminary NMR results show that, relative to control skeletal muscle, nitrate treatment in unexercised fish at rest induces significant increases in metabolic fuels, such as ATP and creatine phosphate, and fuel sources including β -hydroxybutyrate and glycolytic intermediates. After a graded exercise test, the same metabolites increased in control but were decreased in skeletal muscle of nitrate-treated, exercised fish. **CONCLUSIONS:** Our data are consistent with the hypothesis that nitrate treatment may alter lipid and carbohydrate metabolism of zebrafish, in part, through a PPAR- γ mediated mechanism in the liver, and may improve exercise performance through utilization of fuel sources that require less oxygen during exercise. In contrast, our data indicate that nitrite may increase oxygen cost of exercise, in part, by promoting dependence on fatty acid oxidation in the liver of zebrafish.

Performance Enhancing And Pro Regenerative Effects Of Alpha Lipoic Acid Supplementation After Acute And Chronic Resistance And Endurance Training.

Patrick Diel, Lucas Trittel, Eduard Isenmann. *Geman Sports University Cologne, Cologne, Germany.*
 Email: diel@dshs-koeln.de
 (No relevant relationships reported)

PURPOSE: Oxidative stress is an important key player in the initiation of training induced adaptations but also a risk factor with respect to over training and lack of regeneration. Alpha lipoic acid (ALA) has been described to be a powerful antioxidant. Therefore it was the aim of this study to investigate the effects of acute and chronic ALA supplementation on the regeneration and performance of athletes after intensive exercise. **METHODS:** In this double-blinded, randomised, controlled trial in cross-over design, 17 male resistance and endurance-experienced athletes successfully participated. The subjects were divided into two groups (ALA and Placebo) and underwent a standardized acute (3sets back squats of 12 reps each and 3 sets of low jumps with 15 reps each) and chronic training protocol (6 days of intensive resistance and endurance training). Between the acute and chronic training experiments was a 4-week break. At certain time points before and after exercise (T0, T1 (+24h) and T2 (+7d)) blood samples were taken and the concentrations of muscle damage (creatine kinase, myoglobin), inflammation (interleukin 6 and 10) and oxidative stress (ox LDL) markers were investigated. In addition, the maximum performance in the back squat was measured at all timepoints. **RESULTS:** In the 6 day chronic training intervention a clear inhibition of muscle damage and inflammation could be observed in individuals under chronic supplementation of ALA compared to the control group. Whereas performance in the back squat was significantly reduced after 6 day of chronic training in the placebo group no significant loss of performance could be detected in the ALA group. In contrast after an acute training a single application of ALA did not result in significant differences between the placebo and ALA groups with respect to all before mentioned markers and back squat performance. **CONCLUSIONS:** Based on these data we conclude that that ALA supplementation has only limited effects if given acute and directly after exercise but results in remarkably and significant pro-regenerative and performance enhancing effects after chronic supplementation. Mechanistically these effects seem to be mediated via a modulation of the immune response and less by antioxidative effects, which needs to be investigated in more detail in future investigations.

2763 Board #224 May 29 9:30 AM - 11:00 AM
Effects Of Combined Rhodiola And Cordyceps On VO₂Max, Blood Glucose, And Lactate

Cameron Swick, Karen Yagi, Cami Christopher, Jessica Bouchard, Jenna Rohlf, Nicole Conyers, Austin San, Tyra Saelee, Rachel Barnett, Peter Gault, Isaac Johnson, Kieran Kearney, Jun Kwon, Sarah Pope, Cannon Wong, Todd Hagobian, FACSM. *California Polytechnic State University, San Luis Obispo, CA.* (Sponsor: Todd Hagobian, FACSM)
 (No relevant relationships reported)

Rhodiola and Cordyceps are two common herbal supplements that have been shown to increase VO₂ max and exercise performance, but limited research has examined the combined effects. **PURPOSE:** To determine the combined effects of Rhodiola and Cordyceps (R+C) supplementation, compared to Rhodiola alone (R) and placebo (PL), on VO₂ max, blood glucose and lactate concentrations. **METHODS:** 13 physically active college students (7M, 6F; Mean ± SD; 21.08 ± 1.55 yrs, 22.60 ± 2.29 kg/m²) completed three conditions in a counterbalanced, crossover, double-blinded fashion; 1) PL (250 mg calcium), 2) R (250 mg Rhodiola), 3) R+C (250 mg Rhodiola + 225 mg Cordyceps). In response to each condition, VO₂ max (assessed by Bruce Protocol), blood glucose and lactate (via fingerstick) were examined using an ANOVA. **RESULTS:** There was no significant condition effect for VO₂ max between PL, R, and R+C (P=0.80; Mean ± SD; 50.42 ± 8.75, 51.08 ± 7.44, 50.76 ± 7.64 mL/kg/min). There was no significant condition x time interaction for blood glucose (P=0.99). However, compared to PL, blood glucose was significantly higher in R+C (P=.047; LSM ± SEM; 104.97 ± 2.91, 113.08 ± 2.91 mg/dL). There was no significant condition or condition x time interaction in blood lactate concentrations between conditions (Ps>0.05). **CONCLUSION:** Our preliminary data suggest that R+C had no effect on VO₂ max or blood lactate concentrations, but increased blood glucose concentrations. Future studies are needed to examine ventilatory threshold and other markers of exercise performance in response to these supplements.

Effects Of Short-term Continuous Montmorency Tart Cherry Juice Supplementation In Participants With Metabolic Syndrome
 Terun Desai, Michael Roberts, Lindsay Bottoms. *University of Hertfordshire, Hatfield, United Kingdom.*
 Email: t.desai@herts.ac.uk
 (No relevant relationships reported)

PURPOSE: The prevention of cardiovascular disease (CVD) and type II diabetes mellitus (T2D) would be a major step in retarding rising global prevalence and incidence rates. Metabolic Syndrome (MetS) augments the incidence of CVD by 2-fold and T2D by 5-fold. Montmorency tart cherries are rich in phytochemicals and have previously been shown to improve cardio-metabolic biomarkers in humans. This study aimed to examine cardio-metabolic responses after 7 days Montmorency tart cherry juice (MTCJ) supplementation and also acute responses to a single-bolus, in humans with MetS.

METHODS: In a randomised, single-blind, placebo-controlled, crossover trial, twelve participants with MetS (50 ± 10 y; 6M/6F), consumed MTCJ or placebo (PLA) for 7 days. Blood-based (serum glucose, insulin, lipid profile) and functional (cardiac haemodynamics, arterial stiffness and resting metabolic rate) cardio-metabolic biomarkers were measured pre- and post-supplementation, and acute responses measured pre-bolus and up to 5 hours post-bolus on the 7th day. Comparisons were made by two-way, repeated measures ANOVA design.

RESULTS: 24-hour ambulatory systolic (PLA vs. MTCJ, 2 ± 1 vs. -5 ± 1 mmHg, $P = 0.016$), diastolic (2 ± 1 vs. -2 ± 1 mmHg, $P = 0.009$) blood pressure and mean arterial pressure (3 ± 1 vs. -2 ± 0 mmHg, $P = 0.041$) were significantly lower after 7 days MTCJ supplementation compared to PLA. Findings also showed a significant reduction in glucose (0.03 ± 0.07 vs. -0.50 ± 0.00 mmol.L⁻¹, $P = 0.038$), total cholesterol (0.04 ± 0.06 vs. -0.40 ± 0.07 mmol.L⁻¹, $P = 0.036$), LDL (0.26 ± 0.09 vs. -0.36 ± 0.14 mmol.L⁻¹, $P = 0.023$) concentrations and total cholesterol:HDL ratio (0.13 ± 0.00 vs. 0.02 ± 0.00 , $P = 0.004$) with concomitant lower resting respiratory exchange ratio values (0.01 ± 0.02 vs. -0.03 ± 0.00 , $P = 0.009$) after 6 days MTCJ consumption compared to PLA.

CONCLUSIONS: This study revealed for the first time MTCJ to significantly improve 24-hour BP, fasting glucose, total cholesterol and total cholesterol:HDL ratio, and also lower resting respiratory exchange ratio compared to a control in any human population. Responses demonstrated clinically relevant improvements on aspects of cardio-metabolic function, emphasising the potential efficacy of MTCJ in preventing further cardio-metabolic dysregulation in an 'at risk' population.

2765 Board #226 May 29 9:30 AM - 11:00 AM
THE EFFECT OF CALANUS FINMARCHICUS OIL (CALANUS® OIL) ON MAXIMAL OXYGEN UPTAKE: A RANDOMIZED CONTROLLED STUDY
 Trine Karlsen¹, Lucas Tauchek², Ragnhild Røsbjerg², Håvard Dalen², Terje Larsen³. ¹Nord University, Bodo, Norway. ²Norwegian University of Science and Technology, NTNU, Trondheim, Norway. ³The Arctic University of Norway, Tromsø, Tromsø, Norway.
 Email: trine.karlsen@nord.no
 (No relevant relationships reported)

PURPOSE: to investigate the long-term effect of daily Calanus® Oil supplementation on maximal oxygen uptake (VO_{2max}) in healthy 30-50 year old human participants. VO_{2max} is the single best measure of human endurance capacity, as well as a predictor of longevity and cardiovascular disease mortality. Systematic exercise training increases VO_{2max} and has beneficial health effects. The copepod-based omega-3 rich Calanus® Oil supplementation has previously been shown to increase VO_{2max} in diet-induced obese mice. The present study is a follow-up study in healthy human participants.

METHOD: in a double-blinded study, 71 participants were randomized to receive 2 grams · day⁻¹ of Calanus® Oil or placebo supplementation for a total of 6 months. The participants underwent exercise testing and clinical investigations at baseline, 3 months and 6 months. The main study outcome was change in VO_{2max} from baseline to 6 months. Results are given as mean ± standard deviation.

RESULTS: a total of 58 participants (baseline age, years: Calanus® Oil, 39.7 ± 4.5 and placebo, 38.8 ± 5.3 ; baseline BMI, kg · m⁻²: Calanus® Oil, 24.8 ± 2.2 and placebo, 24.8 ± 2.8 ; baseline VO_{2max} , ml · kg⁻¹ · min⁻¹: Calanus® Oil, 50.4 ± 9.1 and placebo 50.2 ± 8.8) completed the 6-month test and were included in the final data analysis. There were no between group differences at baseline. There were no between group changes in VO_{2max} measured in L · min⁻¹ (Calanus® Oli, 3.78 ± 0.79 and placebo, 3.79 ± 0.90) or normalized to body weight (Calanus® Oil 50.1 ± 9.6 ml · kg⁻¹ · min⁻¹ and Placebo 49.5 ± 9.2 ml · kg⁻¹ · min⁻¹) from baseline to 6 months (6 month values). No other clinical measures changed over the 6-month study period.

CONCLUSION: Six months of Calanus® Oil supplementation did not change maximal oxygen uptake in physically fit, healthy, normal to overweight middle age men and women between 30-50 years of age.

Polyphenol Rich Supplementation On Markers Of Recovery From Intense Resistance Exercise
 David R. Hooper, Terrance W. Orange, Meagan T. Gruber, Kara L. Conway, Heather S. Hausenblas. *Jacksonville University, Jacksonville, FL.*
 Email: dhooper4@ju.edu
 Reported Relationships: **D.R. Hooper:** Industry contracted research; This research was funded by a research grant from Specnova, Inc..

PURPOSE: The purpose of this study was to assess whether polyphenol supplementation, previously shown to have anti-oxidative properties, reduces muscle damage and soreness and whether the recovery of physical performance is enhanced as a result.

METHODS: 15 men (mean age: 26.2 ± 5.3 years; height: 184.3 ± 8.2 cm; weight: 92.9 ± 15.6 kg; barbell back squat 1RM: 146.8 ± 30.6 kg) completed a randomized, cross-over, placebo controlled design where subjects performed 6 sets of 10 barbell back squats at 80% 1-repetition maximum and were assessed for markers of recovery immediately, 1-, 3-, 24- and 48-hours following the protocol on two occasions; once following 1 week of 500mg of tart cherry supplementation (TC) and once following a placebo (PL) supplement. Markers of recovery included plasma creatine kinase MB isoenzyme (CKMB), muscle soreness by visual analog scale, countermovement vertical jump height (CMJ) by forceplate, and grip strength by isokinetic dynamometer.

RESULTS: With regards to muscle damage, there was a statistically significantly ($p=0.003$) greater increase in CKMB concentration in the PL when compared to the TC group (PL: 21.1 ± 11.5 ng · ml⁻¹ vs. TC: 0.0 ± 11.3 ng · ml⁻¹) 60 min post. There was a statistically significantly ($p=0.015$) higher increase in muscle soreness in the PL when compared to the TC group (PL: 5.2 ± 2.9 cm vs. TC: 3.2 ± 1.3 cm) at 48 hours. There were no statistically significant differences in jump power or handgrip dynamometer strength, although there was a trend ($p=0.08$) towards significance (PL: -0.1 ± 3.4 kg vs. TC: 1.5 ± 2.9 kg) in grip strength change.

CONCLUSIONS: In conclusion, polyphenol supplementation was shown to reduce soreness following intense resistance exercise. In addition, polyphenols were shown to reduce CKMB, a marker of cardiac muscle damage. In this study, the damage protocol was not sufficient to cause reductions in power performance, and thus the supplement was unable to demonstrate reduced attenuations of performance as a result of the decreased damage.

Effect Of Acute Beclomethasone And Prednisolone On 40-km And Recovery For Subsequent 10-km Cycling Time-trial
 William Gowers¹, Mike Loosemore², James Hopker¹, John Dickinson¹. ¹University of Kent, Chatham, United Kingdom. ²Institute of Sport Exercise & Health, London, United Kingdom.
 Email: W.E.Gowers@kent.ac.uk
 (No relevant relationships reported)

The World-Anti Doping Agency (WADA) stipulates that athlete use of glucocorticoid medication for asthma related conditions requires a therapeutic-use-exemption (TUE) during competition for oral administration, but not inhaled doses. It remains unclear if glucocorticoid therapy provides a competitive advantage for single, or repeated bout time-trial performance. **PURPOSE:** Compare two methods of acute glucocorticoid administration on 40-km time-trial and recovery for subsequent 10-km time-trial performed on the same day. **METHODS:** Six trained male cyclists (VO_{2max} ; 59.1 ± 3.8 ml · kg · min⁻¹) completed a 40-km time-trial four-hours after administration of prednisolone (0.5 mg · kg⁻¹ body mass, PRED), beclomethasone (1600µg, BEC), microcrystalline cellulose capsules (O-PLA), water vapour inhaler (I-PLA) or control (CON). Following one-hour recovery, participants completed a further 10-km time-trial. Subjective overall recovery score, measured using Acute Recovery Stress Score (ARSS) was completed pre-10-km time-trial. Physiological (Heart-rate; HR, oxygen-uptake; $\dot{V}O_2$) and metabolic response (blood lactate; blood glucose) during 40-km time-trial was recorded. Data was analysed using repeated measure ANOVAs, and Bonferroni post-hoc comparisons. **RESULTS:** No significant difference was seen in completion time (CT) for both 40-km (PRED: 3958 ± 213 s; BEC: 3969 ± 173 s; O-PLA: 4010 ± 169 s; I-PLA: 3978 ± 208 s; CON: 3968 ± 170 s; $p=0.22$) and 10-km (PRED: 950 ± 50 s; BEC: 952 ± 54 s; O-PLA: 956 ± 51 s; I-PLA: 960 ± 50 s; CON: 957 ± 54 s; $p=0.87$) time-trials. No condition time interaction was seen in physiological response (HR: $p=0.69$; $\dot{V}O_2$; $p=0.54$) during 40-km time-trial. PRED resulted in significant enhanced glucose concentration at all exercise time-points ($p>0.05$), but no condition time interaction was evident in blood lactate ($p=0.53$). Subjective overall recovery measured by ARSS was not different between conditions ($p=0.77$). **CONCLUSION:** Acute inhaled or oral glucocorticoid medication did not enhance 40-km time-trial performance. Furthermore, perceived recovery prior to, or measured performance during subsequent 10-km time-trial was not different between conditions.

2768 Board #229 May 29 9:30 AM - 11:00 AM
Effects Of A Single Dose Multi-Ingredient Pre-Workout Supplement On Aerobic Performance In Men And Women

Adrianna R. Houtz¹, Meghan K. Magee¹, Rudy Inaba², Joseph L. Andreacci, FACSM¹, Kyle S. Beyer¹. ¹Bloomsburg University, Bloomsburg, PA. ²Cenegeics, Las Vegas, NV. (Sponsor: Joseph L. Andreacci, FACSM)
 Email: adriannahoutz@gmail.com
 (No relevant relationships reported)

PURPOSE: To assess the effects of a single dose of a multi-ingredient pre-workout supplement (MIPS) on aerobic exercise performance, specifically exercise time and VO_{2max} .
METHODS: 41 college-aged adults (age: 21.8±2.5 y; BMI: 25.1±3.0 kg/m²; men=19; women=22) were recruited to participate in a randomized, double-blind, placebo-controlled, crossover study. All of the participants were tested in the same week, but separated by 48 hours, and were either provided the MIPS or the placebo (PLA) on each day. As per the manufacturer's instructions, following the consumption of the drink, the participants waited 25 minutes to begin the test. Aerobic exercise performance was assessed using the Modified Astrand Treadmill Protocol, during which maximal oxygen consumption (VO_{2max}) and maximal treadmill time were determined. At maximal treadmill time, heart rate (HR), respiratory exchange ratio (RER), and rating of perceived exertion (RPE) were collected. All data were analyzed using gender × trial ANOVAs. In the event of a non-significant interaction, data were analyzed as a single group using dependent t-tests. Alpha level was set to $p \leq 0.05$. All comparisons between PLA and MIPS trials were assessed using Cohen's d effect sizes. All data is presented as mean±standard deviation.
RESULTS: No significant gender × trial interactions were observed for any of the data. However, when assessed as a single group there was a significant difference in VO_{2max} ($p=0.038$) with MIPS (43.8±6.9 mL/kg/min) performing better than PLA (43.0±6.5 mL/kg/min). Furthermore, maximal treadmill time was significantly different ($p=0.016$) with MIPS (9.4±1.9 min) performing better than PLA (9.0±1.8 min). Cohen's d effect sizes revealed that the differences in VO_{2max} ($d=0.111$) and exercise time ($d=0.178$) were trivial. There were no significant differences between PLA and MIPS for HR, RER, or RPE.
CONCLUSIONS: A single dose of this MIPS improved maximal treadmill time and VO_{2max} ; however, these changes were not very large in magnitude. Future research should investigate the long-term effects of using this MIPS.

2769 Board #230 May 29 9:30 AM - 11:00 AM
Effects Of Cannabidiol Supplementation On The Skeletal Muscle Regeneration After Intensive Resistance Training

Eduard Isenmann, Sebastian Veit, Patrick Diel. *Institute for Cardiovascular Research and Sports Medicine, German Sport University Cologne, Cologne, Germany.*
 Email: e.isenmann@dshs-koeln.de
 (No relevant relationships reported)

Cannabidiol (CBD) is a non-psychotropic cannabinoid extracted from cannabis sativa and is mainly sold as a nutrition supplement. The pharmacological effects of CBD are a matter of discussion in research. Anti-inflammatory activities and effects on muscle relaxation of CBD have been demonstrated in studies. However, there is only limited information on the direct effects of CBD on skeletal muscle regeneration (SMR) after physical activity. The **purpose** of this study was to investigate effects of CBD on SMR after intensive resistance training (IRT).
Method: Participants ingested 60mg of CBD or placebo directly after IRT. The study was conducted as a randomized double-blind study in crossover design. Muscle damage as serum creatine kinase (CK) and myoglobin (Myo) as well as performance in 1RM back squat (1RM BS) before and at different times after exercise (+24h, +48h, +72h) are investigated. After the pre-performance tests, 3 sets of BS with 12 repetitions were performed with an intensity of 70%, followed by 3 sets of low jumps with 15 repetitions. Subsequently, the subjects received either a drink with CBD or a placebo drink. No further food was allowed to be consumed in the next 3h. After 24h, 48h and 72h further blood samples were taken and the performance in BS was examined. After two weeks of wash out period, the intervention was repeated. **Results:** CBD administration inhibits significantly the increase of serum CK 24h after exercise (CBD: 244.6U/L SD 65.5 to 332.5U/L SD 97.8, +87.88U/L; PL: 213.8U/L SD 95.0 to 479.9U/L SD 262.6, +265.89U/L) demonstrating a reduction of skeletal muscle damage. However, the 1 RM BS of the CBD group 24h after exercise was significantly lower in comparison to the PL group (CBD: 152.81kg SD 17.90 to 146.26kg SD 16.04, -6.56kg; PL: 150.31kg SD 18.63 to 146.56kg SD 16.85, -3.75kg).
In conclusion, the current results show a reduction of skeletal muscle damage 24h after training through CBD supplementation. However, the 1RM BS also deteriorates at the same time which is very likely caused by skeletal muscle relaxation effects of CBD. To investigate whether these findings can be interpreted as beneficial or adverse with

respect to skeletal muscle regeneration further investigations are currently ongoing to investigate skeletal muscle performance in a time dependent manner after CBD administration.

Effects Of Exercise Training With Green Tea Extract On Cognition, Aerobic Capacity, And Metabolic Biomarkers

Chung-Yu Chen¹, Yi-Ti Yu¹, Chien-Te Ho², Chih-Ling Su³, Yi-Hung Liao⁴. ¹University of Taipei, Taipei, Taiwan. ²Tatung Institute of Technology, Chiayi, Taiwan. ³Taiwan Shoufu University, Tainan, Taiwan. ⁴National Taipei University of Nursing and Health Sciences, Taipei, Taiwan. (Sponsor: Lisa Ferguson-Stegall, FACSM)
 (No relevant relationships reported)

Green tea, a commonly used beverage, is gaining more attention in promoting overall health. Green tea extract (GTE) has been shown to have anti-inflammation and antioxidant functions. Regular exercise training is known to improve aerobic capacity, cognition, and metabolic-related biomarkers. However, it is not well known whether the combination of GTE supplementation during exercise training provides additive benefits. **PURPOSE:** To determine the effects of 6-wk of combined endurance and strength training with GTE supplementation on cognitive function, aerobic capacity and metabolic parameters in young sedentary individuals. **METHODS:** 16 individuals (4 M, 12 F) participated in this double-blind, randomized controlled study. All individuals participated in combined endurance and strength training for 6 wks (60 min/day, 3 days/week), and were randomized to receive either placebo (PLA, N=8, 2 M/6 F; 22.3 ± 2.5 yrs) or GTE (480 mg/day N=8, 2 M/6 F; 23.4 ± 3.6 yrs). Simple cognitive reaction speed, aerobic capacity, and blood metabolic biomarkers (blood glucose and insulin, cholesterol, HDL-C, LDL-C, uric acid and blood urea nitrogen) were measured. **RESULTS:** Improvement in simple cognitive reaction speed was significantly greater in the GTE group compared to the PLA group after training (PLA: -1.05% vs. GTE: 5.36%; $p < 0.05$). Although in both groups the exercise training markedly improved aerobic capacity (PLA: 6.24%; GTE: 7.67%) and increased circulating high density lipoprotein cholesterol (HDL-C) (PLA: 7.96%; GTE: 11.22%) compared to baseline values ($p < 0.05$), there were no differences in these variables between treatments. **CONCLUSIONS:** A 6-wk GTE supplementation may be able to amplify exercise training adaptations in cognitive performance in young sedentary individuals, but aerobic capacity and metabolic biomarkers were not affected after the intervention in this study population.

Effect Of A Commercially-available Nitric Oxide Enhancing Supplement On Cardiometabolic Function
 Nile Banks, Emily M. Rogers, Hannah F. Bryan, Claire M. Smith, Sam R. Emerson, Nathaniel DM Jenkins. *Oklahoma State University, Stillwater, OK.*
 (No relevant relationships reported)

Post-prandial lipemia (PPL) is characterized by high triglycerides (TG), impaired vascular function, and an inauspicious cardiovascular response after the consumption of a meal. **PURPOSE:** We conducted a pilot study to examine if a commercially-available nitric oxide enhancing supplement (NOx) protects against impairments in cardiometabolic function induced by a high-fat meal (HFM). **METHODS:** Eight healthy males (23 ± 3 y, 28 ± 3 kg/m²) provided blood samples and had flow mediated dilation (FMD) assessed prior to (BL), and 1-, 3-, and 5-hours post consumption of a HFM and either 250 mg of NOx or placebo (PLA) during two randomly-ordered visits. Pulse wave velocity (PWV) and pulse wave analysis (PWA) were also performed on 6 of the 8 participants at BL, and 2- and 4-h post-HFM and supplement consumption. Two-way repeated measures ANOVAs were used to examine differences in blood TGs, glucose (GLU) and low density lipoprotein (LDL), as well as systolic (SBP) and diastolic (DBP) blood pressure, heart rate (HR), normalized aortic augmentation index (AIx75), PWV, and %FMD. Mean differences ± 95% CI are provided in the results section when appropriate. The type-I error rate was set a priori at 5%. **RESULTS:** No significant condition × time interactions were observed for any variable (all $p > 0.108$). Significant main effects for time were observed for TRG (BL<1-h [-36 ± 17 mg/dL; $p = 0.001$]; BL<3-h [-86 ± 79 mg/dL; $p = 0.03$]; 3-h>5-h [+40 ± 23 mg/dL; $p = 0.002$]), HR (BL<2-hour [-3.8 ± 3.6 bpm; $p = 0.04$]), and for DBP, LDL, and PWV. However, Bonferroni-corrected post-hoc comparisons revealed no differences among time points in DBP, LDL, or PWV (Figure 1). **CONCLUSION:** Our results confirm that a HFM induces multiple acute, negative cardiometabolic effects. However, our initial analyses indicate that the NOx supplement did not protect against these impairments.

The Effects Of A Protease Enzyme Blend On The Amino Acid Response To Resistance ExerciseJaclyn E. Morimune¹, Jeremy R. Townsend¹, Megan D. Jones¹, Cheryle N. Beuning², Allison A. Haase², Claudia Boot², Laurel Littlefield¹, Ruth Henry¹, Autumn Marshall¹, Trisha VanDusseldorp³, Yuri Feito, FACSM³, Gerald Mangine³.¹Lipscomb University, NASHVILLE, TN. ²Colorado State University, Fort Collins, CO. ³Kennesaw State University, Kennesaw, GA. (Sponsor: Yuri Feito, FACSM)*(No relevant relationships reported)***PURPOSE:** The aim of the current study was to examine the efficacy of whey protein ingestion with or without a protease enzyme complex on amino acid (AA) availability following acute lower-body resistance exercise.**METHODS:** Ten resistance trained men (24.4±4.1yr, 179.1±8.6cm, 92.6±10.4kg) with at least one year of resistance training experience volunteered to participate in this placebo-controlled, randomized, cross-over designed study. Following an overnight fast, participants performed lower-body acute resistance exercises consisting of four sets each of the leg press and leg extension exercises (8-10 repetitions at 75% of 1RM) followed by consumption of one of three drinks of equivalent volume, taste, and appearance which consisted of either: (a) 26g whey protein + 250 mg protease supplement + whey (PW) (b) 26g whey protein (W), or (c) a non-caloric flavored water drink (PL). Blood samples were collected before exercise, immediately-post (0min), 30-, 60-, 90-, 120-, and 180-minutes post-exercise (30min, 60min, 90min, 120min, 180min respectively). Plasma amino acid samples were analyzed for essential (EAA), branched-chained (BCAA), and leucine concentrations via liquid chromatography-mass spectrometry (LC-MS). A 2-way repeated measures analysis of variance (ANOVA) was used to identify differences between treatments over time. Area under the curve was calculated via the trapezoidal technique and analyzed via a one-way ANOVA.**RESULTS:** Significant main effects for time ($p < 0.001$) and time x group interactions ($p < 0.001$) were found for leucine, BCAA, and EAA. PW drink resulted in significantly greater plasma leucine, BCAA and EAA concentrations at 30 min compared to PL ($p < 0.001$) while not different than W. Leucine was significantly elevated at 30min ($p = 0.007$) and EAAs at 180min ($p = 0.004$) compared to 0min for PW and W were both significantly elevated for leucine, BCAAs and EAAs compared to PL ($p < 0.001$).**CONCLUSION:** While no significant differences were found between the W and PW supplementation groups during the 3-hr period after resistance training; the PW group produced significantly greater leucine concentrations at 30min and for EAAs at 180min than PL compared to 0min. Results indicate that PW may provide a modest improvement of AA appearance in blood following acute resistance exercise.

2774 Board #235 May 29 9:30 AM - 11:00 AM

Acute Protease Supplementation Does Not Alter The Endocrine Response To Resistance Exercise In Trained MalesMegan D. Jones¹, Jeremy R. Townsend¹, Jaclyn Morimune¹, Laurel A. Littlefield¹, Trisha A. VanDusseldorp², Yuri Feito, FACSM², Gerald T. Mangine². ¹Lipscomb University, Nashville, TN. ²Kennesaw State University, Kennesaw, GA.

Email: mdjones1@mail.lipscomb.edu

*(No relevant relationships reported)*Proteases are enzymes which aid in the hydrolysis of proteins. Previous work has demonstrated protease supplementation may enhance recovery after high-intensity exercise by decreasing muscle damage and inflammation. While the mechanisms involved are not fully understood, it has been suggested that protease supplementation may alter the endocrine response to exercise, promoting a more favorable recovery state. **PURPOSE:** To determine if protease supplementation immediately after an exercise session influences circulating testosterone, cortisol, insulin, insulin-like growth factor-1 (IGF-1), and growth hormone (GH) concentrations. **METHODS:** Ten resistance trained males (24.1±4.1yr, 69.6±6.8 kg 179±8.6 cm) completed 3 acute lower-body resistance exercise sessions consisting of 4 sets of leg press and leg extension in a randomized, crossover fashion. Each exercise was performed at 75% of participant's previously determined one repetition maximum, for 8-10 repetitions, with 90 seconds of rest between sets. Following the exercise session, participants consumed one of 3 treatments (W: 26g whey; PW: 26g whey + 250mg of a protease enzyme blend; PL: non-caloric control). Blood draws were obtained at baseline (BL), immediately-post (IP), 1-hour (1H) and 3-hours post-exercise (3H) and analyzed for testosterone, cortisol, insulin, IGF-1, and GH. Data for each hormone were analyzed with a 2-way repeated measures analysis of variance (ANOVA), while area under the curve (AUC) values were analyzed with a one-way ANOVA. **RESULTS:** Significant main effects for time ($p < 0.05$) were observed for all hormones. There was a significant decrease in testosterone at IP ($p = 0.007$), 1H ($p < 0.001$), and 3H ($p < 0.001$). There was a significant decrease in cortisol at all time points ($p < 0.001$)compared to BL. There were significant increases in insulin, IGF-1, and growth hormone at all time points ($p < 0.001$) following exercise. Additionally, no interaction for any hormone concentrations or AUC values were seen between treatments in this study. **CONCLUSION:** There were no differential effects of W or PW on the post-exercise endocrine response compared to PL. Therefore, neither protease nor protein supplementation appear to alter endocrine response to resistance exercise in trained males.

The Effects Of 28 Days Of Carnosine Supplementation On Exercise-induced Muscle DamageHaruna Nagatsuka¹, Nanako Hayashi¹, Mikako Sato², Kazusige Goto¹. ¹Ritsumeikan University, Kusatsu, Japan. ²NH Foods Ltd., Tsukuba, Japan.

Email: sh0155hs@ed.ritsumei.ac.jp

*(No relevant relationships reported)*The chicken breast extract contains rich carnosine which plays an antioxidant role (Sato et al., 2012). Therefore, daily carnosine supplementation may attenuate exercise-induced muscle damage response. **PURPOSE:** To examine the effects of the long-term of carnosine supplementation on exercise-induced muscle damage.**METHODS:** Thirteen untrained male subjects were assigned into one of two groups; either carnosine group ($n = 7$; height: 175.2 ± 2.5 cm, body weight: 64.4 ± 1.8 kg, percentage body fat: $12.9 \pm 1.7\%$) or placebo group ($n = 6$; height: 175.1 ± 1.6 cm, body weight: 70.3 ± 4.6 kg, percentage body fat: $17.2 \pm 3.1\%$). They took 1.5g/day of carnosine in carnosine group or placebo supplement in placebo group for 28 days. Before and after supplementation period, the subjects completed a 80 min running (70% $\dot{V}O_{2max}$) to induce muscle damage and inflammatory response. Changes in drop jump (DJ) index, muscle thickness, sores of muscle and blood sample [myoglobin (Mb), creatine kinase (CK), and C-reactive protein (CRP)] were evaluated before exercise and during 24h of post-exercise.**RESULTS:** In both groups, DJ index and muscle thickness did not differ significantly before and after the supplementation period. Sores of muscle were significantly increased after exercise in both groups. However, in the carnosine group, no significant difference was observed between before and post-supplementation period ($p > .05$). Exercise increased significantly serum Mb, CK, CRP levels in both groups ($p < .05$). However, the carnosine group did not present significant difference between before and post-supplementation period ($p > .05$).**CONCLUSIONS:** Long-term (28 days) of carnosine supplementation (1.5/day) did not suppress exercise-induced muscle damage response following endurance exercise in untrained men.

The Effects Of Acute Consumption Of A Brewed Cocoa Beverage On Endothelial Function

Eric E. Noreen, Madison Caldwell, Aoife Schanche, Ari Snaevvarsson. Gettysburg College, Gettysburg, PA.

Email: enoreen@gettysburg.edu

(No relevant relationships reported)

Previous studies have shown that the polyphenol components of cocoa can improve the health and function of blood vessels. It is currently unknown whether consuming a brewed drink made from roasted cocoa beans has the same beneficial effects on blood vessel function.

PURPOSE: The purpose of this study was to assess the acute effects of consuming brewed cocoa on resting blood pressure and endothelial function using near-infrared spectroscopy (NIRS) to evaluate changes in tissue oxygen saturation (StO_2) following blood vessel occlusion.**METHODS:** A total of 15 healthy college-aged adults participated in this study. StO_2 levels were monitored continuously throughout the test using a NIRS device placed on the flexor digitorum profundus of the dominant arm. Baseline StO_2 levels were measured for 5 minutes following 10 minutes of supine rest, after which blood flow to the forearm was occluded for 3 minutes using a blood pressure cuff inflated to 50mmHg above resting systolic pressure, followed by a 5-minute period of reperfusion following release of the cuff. Subjects then consumed either plain water, or the cocoa treatment (40g of roasted cocoa brewed for 10 minutes), and all testing was repeated 90 minutes later. Subjects returned to the lab on a separate day to repeat the test using the opposite beverage.**RESULTS:** The change from baseline was not significantly different between water (W) and cocoa (C) for resting heart rate ($C = -6.6 \pm 6.5$ bpm, $W = -4.4 \pm 7.0$ bpm; $p = 0.29$), resting systolic blood pressure ($C = 0.9 \pm 4.5$ mmHg, $W = -2.2 \pm 7.4$ mmHg; $p = 0.10$), resting diastolic blood pressure ($C = -1.1 \pm 6.7$ mmHg, $W = 0.8 \pm 4.5$ mmHg; $p = 0.39$), pre-occlusion StO_2 ($C = 1.6 \pm 5.6\%$, $W = -1.9 \pm 6.9\%$; $p = 0.06$), minimum StO_2 during occlusion ($C = -0.6 \pm 10.5\%$, $W = -0.7 \pm 12.8\%$; $p = 0.98$), reperfusion maximum StO_2 ($C =$

0.5±3.6%, $W = -0.8 \pm 5.0\%$; $p = 0.40$), or reperfusion rate quantified as the slope of the StO_2 during the first 10 seconds of reperfusion ($C = 0.1 \pm 0.4\% s^{-1}$, $W = 0.06 \pm 0.4\% s^{-1}$; $p = 0.79$).

CONCLUSION: Consumption of a brewed cocoa drink does not significantly affect markers of endothelial function or blood pressure in healthy college-aged adults.

Chronic Alcohol Consumption In Female Mice Yields Strain Dependent Differences In Muscle Atrophy

Joseph A. Laudato, Abby L. Tice, Kirsten R. Dunlap, Zachary A. Keith, Jennifer L. Steiner. *Florida State University, Tallahassee, FL.* (Sponsor: Ellen Glickman, FACSM)
(No relevant relationships reported)

Differences in alcohol preference between mouse strains is well known, yet there are no reports of whether alcohol non-preferring mice experience alcoholic myopathy. **PURPOSE:** To determine whether the intake and response to chronic alcohol feeding differs between alcohol preferring (C57BL/6) and non-preferring (CD2F1) mice. **METHODS:** Female C57BL/6 (n=16) and CD2F1 (n=6) mice aged 12-weeks-old were acclimated to a liquid diet (1 wk) prior to randomization into either a control (CON) or alcohol (EtOH) treatment group: B6-CON, B6-EtOH, CD2-CON, and CD2-EtOH. Alcohol was incorporated into the diet and daily consumption of EtOH was assessed relative to body weight. After 7 weeks the gastrocnemius (GAS), tibialis anterior (TA), and quadriceps (QUAD) muscles were excised, weighed and are expressed relative to body weight. Blood was collected from the vena cava and separated into plasma for blood EtOH concentration at time of sacrifice (BAC). The spleen and heart were also removed and weighed. Data were analyzed via 2-way ANOVA for variables across time, and unpaired t-tests were used to detect differences within each strain. **RESULTS:** A group x time interaction was observed for EtOH consumed ($F = 3.010$, $p < 0.001$), where B6-EtOH consumed a greater amount of EtOH compared to CD2-EtOH weeks 3-7 ($p < 0.038$). However, at time of sacrifice, no differences were observed for BAC between the strains ($p = 0.22$). Alcohol intake reduced GAS weight similarly in both strains (B6: $-9.67 \pm 4.15\%$; $p = 0.037$; CD2: $-12.07 \pm 3.19\%$; $p = 0.019$), and muscle weights also did not differ between strains following alcohol intake ($p = 0.06$). QUAD weight was also reduced by alcohol consumption in the CD2 mice ($-17.68 \pm 4.56\%$; $p = 0.02$), while no significant atrophy was observed in the B6 mice. Conversely, B6 mice had a significant reduction in heart weight following chronic alcohol intake ($p = 0.014$; $-13.03 \pm 4.58\%$), while the CD mice showed no effect. Finally, alcohol feeding did not alter spleen weight or TA weight in either strain ($p > 0.05$). **CONCLUSION:** The non-alcohol preferring CD2F1 mice experienced a greater loss of muscle mass in response to chronic alcohol feeding, despite consistently consuming a lower dose of alcohol. Future work will be needed to determine what molecular pathways contributed to the enhanced catabolic effect of alcohol in this strain of mice.

Pistachios May Promote Recovery From Strenuous Exercise

Imogene Azalea Carson, Mark Kern PhD, RD, Shirin Hooshmand PhD, RD, Changqi Liu PhD, Mee Young Hong PhD, RD, Tim O'neal RD, Aj Munoz, Jillianne Son. *San Diego State University, San Diego, CA.* (Sponsor: Michael Buono, FACSM)
(No relevant relationships reported)

Among nuts, pistachios are considered a rich source of leucine. They are also a good source of antioxidants. These are compounds known to promote muscle protein synthesis and reduce inflammation respectively. Therefore, we hypothesize that pistachios may confer favorable effects to athletes following strenuous exercise.

PURPOSE: to determine if pistachio nut consumption for two weeks prior to and during three days of recovery from vigorous, eccentrically biased exercise improves muscles soreness, vertical jump height and muscle strength in a dose (0, 1.5 oz and 3.0oz per day) dependent manner.

METHODS: Using a randomized, crossover approach, nine active men (N=9), (25.5 ± 5yrs, 175.3 ± 5.6 cm, 76.0 ± 9.4 kg, $VO_2 \text{ peak} = 53.3 \pm 9.1 \text{ ml/kg/min}$) engaged in three, 40-minute downhill runs after 2-weeks of each dose intervention, with a minimum 3-week washout period between trials. Muscle soreness, vertical jump height and muscle strength were assessed pre-exercise (baseline) and 24-hr, 48-hr and 72-hr post exercise, and subjects continued consuming their specified daily dose throughout the recovery period. Data were analyzed using a 3 x 4 repeated measures ANOVA with post-hoc Paired T-tests when appropriate.

RESULTS: Subjective measures of delayed onset muscle soreness for the RTA were significantly higher in the control trial than the 3.0oz/d trial at 72-hr ($p < .03$). Vertical Jump height decreased 24 hours after the downhill run for the 0oz/d trial only ($p < .03$; 95% CI 0.12 to 1.38). Although no significant differences were detected between

the 0 oz/d trial and the other trials, average muscle torque during leg flexion at two different speeds was higher ($p < 0.05$) at the 48 hour time-point for the 3.0 oz/d trial versus the 1.5 oz/d trial.

CONCLUSIONS: Preliminary analysis suggest that pistachio consumption tended to promote several markers of recovery; however, since blinding research participants was not possible, we cannot eliminate the potential role that a placebo effect may play.

Optimization Of Heart-Brain-Axis Signaling Improves Mental And Physical Performance

Courtney Talbott¹, Lindsey Faucette², Shawn Talbott, FACSM³.
¹California Polytechnic University, San Luis Obispo, CA.
²California Health Sciences University College of Osteopathic Medicine, Clovis, CA. ³Amare Global, Irvine, CA. (Sponsor: Shawn Talbott, FACSM)
 Email: courtneytalbott@gmail.com
(No relevant relationships reported)

PURPOSE: Dynamic changes in heart rate variability (HRV) are considered as markers for autonomic nervous system (ANS) balance and psychological mood states, including depression, anxiety, overtraining, and burnout. HRV is reduced in both depression and heart disease, suggesting common physiological mechanisms. Reduced HRV suggests poor stress adaptation, while increased HRV is associated with vigor (physical energy, mental acuity & emotional well-being). This study assessed the effects of nutritional supplementation on "Heart-Brain-Axis" dynamics whereby nutrition may impact physical (heart) and psychological (brain/mood) parameters in a coordinated manner.

METHODS: Before and after 30-days of supplementation, subjects performed a HRV assessment (emWave Pro; HeartMath Institute) and completed a validated Profile of Mood States (POMS) survey to assess Global Mood (GM) and related subscales: Vigor (V), Tension (T), Depression (D), Anger (A), Fatigue (F), Confusion (C). The supplement (MentaHeart; Amare Global) contained 5 natural ingredients previously shown to have health benefits, including Palm fruit bioactives (redox balance), Astaxanthin (antioxidant), Bergamot (cholesterol), Coenzyme Q10 (cardiac energetics), and Black cumin seed (inflammation).

RESULTS: Following 30-days of supplementation, HRV was improved 11% (SDNN; 47.5msec Pre versus 58.2msec Post) and 19% (RMSSD 3.7 Pre versus 4.4 Post), indicating superior ANS tone and enhanced stress resilience. Psychological Mood State (POMS) parameters showed dramatic improvements following supplementation, with reductions in negative mood states: T (-49%), D (-76%), A (-39%), F (-51%), and C (-62%); with corresponding increases in positive mood states: GM (+23%) and V (+22%).

CONCLUSIONS: Supplementation resulted in a meaningful 11-19% increase in HRV (suggesting a "physical" heart benefit) and also improved mood state parameters (suggesting a "mental" brain benefit). While previous studies have shown individual ingredients to improve general heart/brain health, these data are the first to show that targeted multi-nutrient supplementation supports the multi-faceted psychophysiological "Heart-Brain-Axis" with simultaneous and coordinated improvements in both physical and mental performance.

Astaxanthin Formulation Leads To Greater Lipid Oxidation & Increased Exercise Tolerance In Elderly

Sophia liu¹, Ana Valencia¹, Matt VanDoren², Eric Shankland¹, Kevin Conley¹, David Marcinek¹. ¹University of Washington, Seattle, WA. ²Fed Hutch, Seattle, WA.
 Email: sophia21@uw.edu
(No relevant relationships reported)

Purpose: Natural anti-oxidant and anti-inflammatory products have been found to increase fat oxidation and endurance in animals and humans when combined with exercise training. Here, we test this approach as a treatment for the reduced lipid oxidation and associated lower endurance in human aging using a formulation combining natural anti-inflammatory and anti-oxidant products (AX: astaxanthin, 12 mg; tocotrienol, 10 mg; and zinc, 6 mg). **Methods:** We conducted a randomized, double-blind, placebo-controlled study in the elderly of a daily oral dose (16 weeks) of AX formulation with 12 weeks of exercise training, 3x/week for 40-60 min of increasing intervals of incline walking, targeting 80% HRmax. Cardiovascular endurance and fat oxidation was calculated from respiratory exchange ratio via Balke treadmill test. Tibia anterior (TA) muscle strength and fatigue resistance was measured as force time integral (FTI) in ankle dorsiflexion exercise to fatigue. TA resistance to fatigue was also determined by number of contractions. **Results:** After 12 weeks of training both groups improved treadmill time, only AX group delayed time reach to anaerobic threshold (218±15s vs. 311±32s). Total fat oxidation improved in both group, but AX improved ($\Delta 80.4 \pm 19.4\%$) more compare to training alone ($\Delta 39.2 \pm 10.2\%$). TA fatigue resistance measured by total contractions ($\Delta 184 \pm 77$) and FTI ($\Delta 102 \pm 30$ N) improved only in the AX group. **Conclusion:** AX supplementation

combined with interval training improved whole body fat use significantly more than training alone. Delayed anaerobic threshold in AX group suggested higher exercise capacity. This increased fatigue resistance of the TA in addition to the greater exercise capacity suggests that this metabolic effect is occurring at the level of the individual muscle. The increased fat oxidation and delayed anaerobic threshold may be due to sustained fat use at lower rates of exercise that leads to carbohydrate sparing and ultimately increased carbohydrate availability at more intense exercise levels. The combination of whole body exercise and single muscle fatigue testing removed the training effect (neuromuscular adaptation) that is commonly seen in exercise training. These results indicate that AX supplementation results in greater metabolic adaptation than endurance training alone.

Influence Of Post-exercise Nutrient Intake On Recovery And Subsequent Exercise Performance In Youth Cyclists

Nicholas T. Thomas, Andrew S. Law, Allison T. Cadematori, Nicholas D. Luden, George F. Schultz, Stephanie P. Kurti, Michael J. Saunders, FACSM. *James Madison University, Harrisonburg, VA.* (Sponsor: Michael J Saunders, FACSM)
 Email: thomasnt@dukes.jmu.edu
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to determine if chocolate milk (CM) consumption after high-intensity cycling affected post-exercise recovery and subsequent exercise performance in youth cyclists, compared to carbohydrate (CHO) and placebo (PL) beverages.

METHODS: Eight youth cyclists (15-18 y, $\dot{V}O_{2peak} = 61.8 \pm 7.7$ mL \cdot kg⁻¹ \cdot min⁻¹) completed two exercise sessions on three separate occasions. The first exercise session (EX1) included 30 min of constant-load cycling, and 60 min of standardized high-intensity intervals. Subjects consumed a recovery beverage (PL, CHO or CM) immediately following EX1 and again 2 h after EX1. A standardized lunch was consumed 4 h post-EX1, and a second exercise session (EX2) was completed 7 h after EX1. EX2 consisted of 30 min of constant-load cycling followed by a simulated 30 km time trial (TT). Ratings of muscle soreness, and mental and physical energy/fatigue were obtained prior to EX1, 4 h post-EX1, and pre-EX2. TT power output (W) was used to assess subsequent exercise performance.

RESULTS: Changes in muscle soreness over time were not significantly different between treatments. However, soreness was significantly elevated in PL from pre-EX1 (44 \pm 23 mm) to 4 h post-EX1 (67 \pm 22 mm) and pre-EX2 (68 \pm 20 mm). Soreness tended to be elevated in CHO from pre-EX1 (37 \pm 26 mm) to 4 h post-EX1 (52 \pm 28 mm; $p = 0.051$) but not at pre-EX2, and soreness was not elevated at any post-exercise timepoint in CM. Physical fatigue ratings increased significantly from pre-EX1 to pre-EX2 in PL, but not CHO or CM. In addition, changes in physical fatigue after exercise tended to be less pronounced with CM versus other treatments (p -values for treatment \times time effects: 0.03 - 0.19). Average TT power was similar between PL (181 \pm 27 W), CHO (197 \pm 39 W) and CM (195 \pm 38 W).

CONCLUSIONS: CM ingestion after exercise may confer recovery benefits in youth cyclists, as demonstrated by the absence of elevated muscle soreness and fatigue ratings post-exercise. However, significant treatment \times time effects were not consistently observed across all soreness/fatigue measurements. Subsequent cycling performance was not significantly different between treatments. However, TT performance effects (~8% higher power in CM/CHO versus PL) may be functionally relevant if upheld in trials with larger sample sizes.

The Effects Of Sliver Perch Essence On Body Weight And Endurance Capacity

Kuan-Chen Wu¹, Shioh-Chwen Tsai¹, Chung Yu Chen¹, Yi-Hung Liao². ¹*Institution Of Sports Science, Taipei, Taiwan.* ²*Department of Exercise and Health Science, Taipei, Taiwan.* (Sponsor: Chia-Hua Kuo, FACSM)
 Email: kuanchen1202@gmail.com
 (No relevant relationships reported)

PURPOSE: To investigate the influence of sliver perch essence (SPE) on the anti-fatigue effect and body weight gain (BW). **METHODS:** Thirty-six Wistar rats were weight-matched and assigned into three groups, including: control (water placebo, $n = 12$), L-SPE (6.2 ml/kg BW/day, $n = 12$), and H-SPE (31 ml/kg BW/day, $n = 12$), and SPE were orally administered for 32 consecutive days. The swimming exhaustive test (with 3% BW load attached on the tail) was used to evaluate the swimming endurance performance in response to SPE supplementation. All data were expressed as mean \pm SEM, and ANOVA was used to examine the differences in swimming capacity and BW

change among groups. Duncan multiple range t-test was used as post-hoc test. $P < 0.05$ was considered statistically significant. **RESULTS:** After SPE supplementation, the BW gain was not different among the three groups. However, the BW gain slowed down after the 22nd day, the weight gain of the H-SPE group was significantly lower than that of the control group (11.34%, $p = 0.038$). When normalizing with caloric intake, both L-SPE (-19.75%) and H-SPE (-18.9%) showed significantly less weight-gain compared to control group ($p = 0.016$ and $p = 0.022$, respectively), but there was no difference between L-SPE and H-SPE. The swimming time to exhaustion was significantly higher in the L-SPE but not H-SPE than in the control group ($p = 0.031$). **CONCLUSION:** The results showed that 32-days of SPE supplementation can promote the swimming endurance capacity and attenuate the weight gain in the rodent models.

Effects Of A Demand-valve Scuba Regulator On Cardiovascular Function Under Normobaric Conditions: Preliminary Findings

Christopher R. Kovacs, Camille Dohm. *Western Illinois University, Macomb, IL.*
 Email: cr-kovacs@wiu.edu
 (No relevant relationships reported)

PURPOSE: An increased number of diving fatalities related to cardiac events, leading to loss of air and drowning have been reported (Divers Alert Network, 2018). These events are often preceded by acute physiological stress, such as when presented with situations that increase physiological workload (emergency event, strong current, etc.). Greater cardiorespiratory response, including significant increases in heart rate and cardiac output, often occur as a result of increased stress. Examining equipment factors that influence cardiorespiratory stress during diving has been limited. Therefore, the purpose of this preliminary investigation was to examine the effect of a scuba regulator on cardiorespiratory measures in a group of volunteer participants.

METHODS: Ten participants ($x = 21.5$ yrs.) completed two sub-maximal exercise tests (YMCA Protocol) under sea-level atmospheric conditions on a Monark (Vansbro, Sweden) cycle ergometer until 85% of calculated maximal heart rate was observed. Heart rate, blood pressure, rating of perceived exertion (RPE), and pulse oxygen levels were all collected. The first submaximal test was collected under typical conditions (control). After one week, each participant completed a second submaximal test while breathing compressed air from a demand valve scuba regulator (Dive Rite, FL) connected to an 80 cu/ft aluminum scuba cylinder. All procedures were approved by a university institutional review board prior to data collection.

RESULTS: A descriptive analysis of the data indicated all variable means for the regulator condition (except RPE) were within two standard deviations of the respective mean values for the control condition and therefore considered non-significant. Subsequent post-hoc analysis determined minimum sample sizes required for future research to detect if true differences between groups exist for each variable.

CONCLUSIONS: Preliminary data suggest that breathing from a demand valve scuba regulator does not appear to affect exercise tolerance or increase cardiorespiratory stress at submaximal workloads under normobaric environmental conditions. Future sample size requirements from this preliminary investigation have been determined through statistical analysis and further research with a larger sample appears warranted.

Self-paced Aerobic Exercise Performance Is Attenuated Following Four Hours Cold Water Immersion

Hayden W. Hess¹, Zachary J. Schlader, FACSM², Blair D. Johnson, FACSM¹, David Hostler, FACSM¹. ¹*University at Buffalo, BUFFALO, NY.* ²*Indiana University, Bloomington, IN.* (Sponsor: David Hostler, FACSM)
 Email: haydenhe@buffalo.edu
 (No relevant relationships reported)

It is common for special warfare operators to complete land-based missions following prolonged transport dives. Time to exhaustion during high intensity aerobic exercise is attenuated following cold water submersion, which can be exacerbated when breathing oxygen (O₂). However, the high intensity time to exhaustion model may not be operationally relevant. **PURPOSE:** We tested the hypothesis that self-paced exercise performance following four hours cold water immersion is reduced compared

to a non-immersed control, and that performance would be further reduced when breathing O₂ during immersion. **METHODS:** Eight subjects (4 men and 4 women; age: 25±2y; Body Fat (%): 19.3±5.1; $\dot{V}O_{2max}$: 46±4 mL/kg/min) completed a baseline (CON) performance and two, 4 hour cold water immersion visits (20°C) breathing air or 100% O₂. During CON visit and following immersion, subjects completed a 60 minute loaded ruck-march with 20% body mass (data not shown) followed by a self-paced 5 km run on a motorized treadmill. Core temperature, heart rate, and rating of perceived exertion (RPE) were recorded every 500 m during the run. **RESULTS:** 5 km run time was reduced following immersion while breathing 100% O₂ ($p=0.006$) and air ($p=0.007$) compared to the CON (32±6 min vs. 32±5 min vs. 28±4 min, respectively). However, there was no difference between air and O₂ ($p=0.86$). Core temperature increased during the 5 km run ($p<0.001$), but was not different between conditions ($p=0.96$). Heart rate increased during the 5 km run ($p<0.001$), but was not different between conditions ($p=0.49$). Finally, RPE increased during the run ($p<0.001$), but was not different between conditions ($p=0.73$). **CONCLUSION:** These findings suggest that prolonged cold water immersion attenuates self-paced aerobic endurance performance, but does not appear to be further affected by breathing gas type (i.e., air vs. 100% O₂). However, the mechanisms for this attenuated post-immersion performance remain largely unknown.

Effects Of Environmental Condition And Body Fat Percentage On Metabolic Efficiency During Cycling Exercise

Brittany N. Followay¹, Jeremiah A. Vaughan², Ellen L. Glickman, FACSM³, Adam R. Jajtner³. ¹Ripon College, Ripon, WI. ²Bemidji State University, Bemidji, MN. ³Kent State University, Kent, OH. (Sponsor: Ellen Glickman, FACSM)
 (No relevant relationships reported)

PURPOSE: To examine the effects of environmental condition and body fat percentage on metabolic efficiency during cycling exercise.

METHODS: Recreationally active men consisting of 4 low-fat (LF; 10.9% ± 2.5; 23.8 ± 3.1yrs; 182.6 ± 7.1cm; 80.7 ± 4.5kg; 4.03 ± 0.34L·min⁻¹) and 4 high-fat (HF; 15.9% ± 2.2; 23.3 ± 1.9yrs; 180.9 ± 4.3cm; 79.6 ± 5.9kg; 3.63 ± 0.13L·min⁻¹) completed 2 experimental trials in 5°C/20% RH (LT) and 22°C/45% RH (MT) in a counterbalanced fashion. Participants completed 60-min of cycling at 60% $\dot{V}O_{2max}$. Metabolic efficiency was calculated during cycling at 3min, 15min, 30min, 45min, and 60min. Data were analyzed using a three-way repeated measures mixed-design ANOVA. **RESULTS:** A time x BF interaction was observed ($F=4.147$; $p<0.001$). Post hoc analysis indicated a main effect of time in LF ($F=11.983$; $p<0.001$) and HF ($F=24.086$; $p<0.001$) individuals. Specifically, significant decreases in metabolic efficiency were observed at 15min, 30min, 45min, and 60min compared to 3min ($p < 0.05$) in LF individuals, with no further reductions observed at 45min ($p=0.732$) and 60min ($p=0.598$) compared to 30 min. In HF individuals, significant decreases in metabolic efficiency were observed at 15min, 30min, 45min, and 60min compared to 3min ($p < 0.05$), with further reductions observed at 45min ($p=0.021$) and 60min ($p < 0.001$) compared to 15min, and at 60min compared to 30min ($p=0.005$) and 45min ($p=0.002$). Furthermore, a condition x time interaction ($F=3.351$; $p=0.026$) was observed. A main effect of time was observed for the LT condition ($F=22.436$; $p<0.001$) and MT condition ($F=20.850$, $p<0.001$), with significant decreases at 15min, 30min, 45min, and 60min compared to 3min ($p < 0.05$) during both the LT and MT conditions. Furthermore, paired samples t-test indicated significantly lower metabolic efficiency in the MT condition compared to the LT condition at 45min (MT; 19.17 ± 1.6%; LT; 20.2 ± 1.6%; $p=0.20$) and 60min (MT; 18.88 ± 0.63%; LT; 19.16 ± 0.68% $p=0.49$). **CONCLUSIONS:** Data suggests that individuals with a higher % BF may experience greater decreases in metabolic efficiency throughout prolonged cycling exercise at moderate intensity. Additionally, metabolic efficiency appears to decrease throughout cycling exercise, with cold environments resulting in greater efficiency compared to MT conditions.

2787 Board #248 May 29 10:30 AM - 12:00 PM
Brain Derived Neurotrophic Factor Response To Aerobic Exercise In The Cold

Carly Sedlacek, Ryan T. Wiet, Emily C. Tagesen, Eliott Arroyo, Ellen L. Glickman, FACSM, Adam R. Jajtner. Kent State University, Kent, OH. (Sponsor: Ellen Glickman, FACSM)
 Email: csedlac1@kent.edu
 (No relevant relationships reported)

PURPOSE: To examine changes in brain derived neurotrophic factor (BDNF) concentration in both plasma and serum following exercise in the cold. **METHODS:** Six recreationally active men (26 ± 3 yrs; 180.3 ± 5.8 cm; 85.3 ± 8.4 kg; 48.6 ± 5.7 ml·kg⁻¹·min⁻¹) completed an exercise protocol under two conditions: moderate temperature (MT; 23°C/45%RH) and low temperature (5°C). The protocol consisted of a 60-minute cycling trial at 60% $\dot{V}O_{2max}$, a 15-minute rest, and a time-to-exhaustion trial at 90% $\dot{V}O_{2max}$ (TTE). Blood was collected before (T1) and after

(T2) the 60-minute trial, immediately after TTE (T3), and one hour post-TTE. Plasma and serum concentrations of BDNF were measured via ELISA. Changes were analyzed using separate condition by time mixed-model regression for each dependent variable. **RESULTS:** No significant condition × time interaction ($F = 1.626$, $p = 0.201$) or main effect of time ($F = 0.626$, $p = 0.603$) was observed for changes in serum BDNF concentrations; however, a significant main effect of condition ($F = 7.685$, $p = 0.009$) was observed. When collapsed across time, serum BDNF concentration was significantly lower during LT (2718.8 ± 1172.2 pg/mL) compared to MT (7240.5 ± 1134.2 pg/mL; $p = 0.009$). No significant condition × time interaction ($F = 0.117$, $p = 0.950$), main effect of time ($F = 0.511$, $p = 0.677$) nor main effect of condition ($F = 0.000$, $p = 0.988$) was observed for changes in plasma BDNF concentrations. **CONCLUSIONS:** The results of this study suggest that exercise in a cold environment (5°C) blunts serum BDNF concentration. However, plasma concentrations of BDNF were not affected by environmental condition nor exercise. Previous research has found no relationship between serum and plasma BDNF, suggesting that these are independent measures of diverse physiological relevance. Peripheral BDNF is predominantly stored in platelets (~99%), with only a small amount of free BDNF present in plasma. Due to the smaller amount of platelet-associated BDNF in plasma, plasma concentrations of BDNF may reflect the amount of free BDNF. Therefore, exercise in a cold environment may decrease BDNF release from platelets while having no effect on free BDNF.

This study was partially funded by the Kent State University Research Council.

Effects Of Exercise Training In A 7°C Environmental Temperature Exercise Training Period

Nathanael O'Reilly. University of Nebraska Omaha, Omaha, NE. (Sponsor: Dustin Slivka, FACSM)
 (No relevant relationships reported)

Purpose: To determine the impact of cold environmental temperature on endurance exercise training adaptations. **Methods:** Two groups of twelve untrained male subjects completed sixteen 1-hour of cycling sessions in either 7°C or 20°C environmental temperature. Fitness assessments before and after acclimation occurred in standard room temperature. Muscles biopsies were taken from the vastus lateralis before training and after training to assess molecular markers related to mitochondrial development. **Results:** PGC-1 α mRNA was higher in 7°C than 20°C in response to acute exercise before training ($p=0.012$) but not after training ($p=0.813$). PGC-1 α mRNA was lower after training ($p<0.001$). BNIP3 was lower after training in the 7°C than the 20°C group ($p=0.017$), but not before training ($p=0.549$). No other differences occurred between temperature groups in mRNA of VEGF, ERR α , NRF1, NRF2, TFAM, PINK1, Parkin, or BNIP3L ($p>0.05$). PGC-1 α protein and mtDNA were not different before training, after training, or between temperatures ($p>0.05$). Cycling power increased during the daily training ($p<0.001$) but was not different between temperatures ($p=0.169$). $\dot{V}O_{2peak}$ increased with training ($p<0.001$) but was not different between temperature groups ($p=0.460$). **Conclusions:** These data indicate that cold environmental temperatures alter PGC-1 α gene expression acutely, but this difference is not manifested throughout a training period as increased fitness.

2789 Board #250 May 29 10:30 AM - 12:00 PM
Effect Of Continuous Cold-Water Immersion Recovery Protocol On Locomotion Performance During A Congested-Fixture Handball Tournament

Braulio Sánchez-Ureña¹, Daniel Rojas-Valverde¹, Jose Pino-Ortega², Jose A. Trejos-Montoya¹, Alexis Ugalde-Ramírez¹, Juan C. Gutiérrez-Vargas¹, Randall Gutiérrez-Vargas¹, Jeffrey Mjaanes, FACSM³. ¹National University of Costa Rica, Heredia, Costa Rica. ²University of Murcia, Murcia, Spain. ³Northwestern University, Evanston, IL. (Sponsor: Jeffrey M. Mjaanes, FACSM)
 Email: brau09@hotmail.com
 (No relevant relationships reported)

Cold water immersion (CWI) is a commonly recommended recovery technique for athletes. Few studies, however, have analyzed the effects of CWI protocols, specifically in internal and external load in congested fixture tournament. The purpose of this study was to explore the effectiveness of continuous cold water immersion (CCWI) protocols and passive recovery on kinematic performance of handball players. A total of 32 (19 women and 13 men), members of eight clubs took part of a congested tournament (3 days, a match per day, total of twelve matches). Inertial measurement devices were attached to each player's back at the inter-scapular T2-T4 level. External load (relative distance, accelerations, maximum acceleration, maximum and average speed, total impacts, accelerations/decelerations difference, and player load) and internal load (maximum and average heart rate) were assessed using these devices. Participants were randomly divided into two recovery groups: a) CCWI group (12°C for 12min), sitting during immersion with their legs completely extended, and the

water reaching navel height, and b) control group (23°C, 12min passive, sit rest in similar body position). Mixed analysis of variance (ANOVA) was used, to verify the possible differences between matches and recovery protocols for each variable. There were no differences in internal or external load variables between recovery groups during tournament in men or women (see figure 1.). Continuous cold water immersions and passive recovery are both effective to maintain the external and internal physical demands during a congested tournament in handball.

Variable	Men	Women
Relative distance (m/min)	($F_{(2,37)}=.272, p=.764, \omega_p^2=-.04$)	($F_{(2,49)}=.186, p=.831, \omega_p^2=-.02$)
Accelerations	($F_{(2,37)}=.02, p=.981, \omega_p^2=-.06$)	($F_{(2,49)}=.865, p=.428, \omega_p^2=0$)
Maximum acceleration (m/s ²)	($F_{(2,37)}=.302, p=.742, \omega_p^2=-.05$)	($F_{(2,49)}=.073, p=.93, \omega_p^2=-.3$)
Maximum speed (km/h)	($F_{(2,37)}=.1.021, p=.372, \omega_p^2=0$)	($F_{(2,49)}=.439, p=.648, \omega_p^2=-.02$)
Average speed (km/h)	($F_{(2,37)}=.279, p=.758, \omega_p^2=-.04$)	($F_{(2,49)}=.059, p=.946, \omega_p^2=-.3$)
Maximum heart rate (bpm)	($F_{(2,37)}=.01, p=.995, \omega_p^2=-.06$)	($F_{(2,49)}=.466, p=.63, \omega_p^2=-.02$)
Average heart rate (bpm):	($F_{(2,37)}=.103, p=.903, \omega_p^2=-.06$)	($F_{(2,49)}=.511, p=.603, \omega_p^2=-.01$)
Total impacts (n)	($F_{(2,37)}=.13, p=.879, \omega_p^2=-.06$)	($F_{(2,49)}=.016, p=.984, \omega_p^2=-.3$)
Acceleration/deceleration difference (m/s ²)	($F_{(2,37)}=.1.292, p=.289, \omega_p^2=0$)	($F_{(2,49)}=.725, p=.489, \omega_p^2=0$)
Player load (au)	($F_{(2,37)}=.097, p=.908, \omega_p^2=-.02$)	($F_{(2,49)}=.172, p=.843, \omega_p^2=-.02$)

E-35 Free Communication/Poster - Hypoxia/Altitude Physiology

Room: CC-Exhibit Hall

2790 Board #251 May 29 10:30 AM - 12:00 PM EFFECT OF LIGHT-MODERATE EXERCISE AT ACUTE NORMOBARIC HYPOXIA ON ELECTROENCEPHALOGRAM AND PHYSIOLOGICAL RESPONSES

Jin Uchimar, Fan, J. Liu. *Sendai University, Shibata, Miyagi, Japan.*
Email: jn-uchimar@sendai-u.ac.jp
(No relevant relationships reported)

It is well known that hypoxic stress causes various physiological responses and/or adaptations. Hypoxia also affects brain activities such as cognition, judgment and exercise performance, and it is thought that the influence on electroencephalogram (EEG) is great. However, there are few researches related to the change of EEG to hypoxia *per se* and exercise at hypoxia, and it is thought that the mechanisms underlying the physiological responses including brain activity of hypoxic stress *per se* and exercise at hypoxia were not fully understand. **PURPOSE:** The purpose of this study was to examine that effect of light-moderate exercise at acute normobaric hypoxia on EEG and physiological responses. **METHODS:** Eleven college-age male subjects were participated in this study. They completed the light-moderate exercise (50-65%HRmax) at both normoxia and normobaric hypoxia (14.5% hypoxia). We measured EEG of left forehead, heart rate (HR), and oxygen saturation (SpO₂) before and after exercise. EEG measurement was carried out in a quiet environment, and subjects measured with their eyes closed. The measured EEG was classified into 3 frequency bands. In other words, it was classified into θ wave 4 to 7.5 Hz, α wave 8 to 13 Hz, β wave 13.5 to 30 Hz. The average value (μ V) of the amplitude of the EEG and the total amplitude of the EEG in the entire frequency band (3 to 30 Hz) were obtained for each measurement for 10 minutes. Repeated measures ANOVA were performed across treatments. **RESULTS:** SpO₂ at rest and during moderate exercise in hypoxia was significantly lower than that of normoxia (hypoxia; 89.0±2.2% at rest, 82.1±4.4% during exercise, normoxia; 96.8±1.5% at rest, 96.6±1.5% during exercise, p<0.05). HR at rest and during moderate exercise in hypoxia was significantly higher than that of normoxia (p<0.05). The average value of α wave tended to increase after exercise in normoxia from 3.08±0.79 to 3.26±0.96 μ V. On the other hand, α wave tended to slightly decrease after exercise in hypoxia from 2.96±0.85 to 2.84±0.82 μ V. The average value of θ and β wave did not change after exercise at both environments.

CONCLUSIONS: From these results, light-moderate exercise in hypoxia could attenuate α wave expression by decreasing SpO₂. It would be affect the exercise performance and acclimatization at altitude, as well as cognition.

2791 Board #252 May 29 10:30 AM - 12:00 PM Resistance Training Alleviates Hypoxia-induced Skeletal Muscle Atrophy Of Rats By Inhibiting FoxO1-mediated Autophagy Pathway

Pengyu Fu, Yang HU, Lijing GONG. *Beijing Sport University, Beijing, China.*
Email: 1402884452@qq.com
(No relevant relationships reported)

PURPOSE: The aim was to investigate the effects of resistance training on hypoxia-induced muscle atrophy and the regulation of FoxO1-mediated autophagy. **METHODS:** SD rats were divided into the normoxic control group (C), the normoxic resistance training group (R), the hypoxic control group (H), and the hypoxic resistance training group (HR). Group R and HR were trained by incremental load ladders every other day; Group H and HR lived in a hypoxia with 12.4% O₂ for 4 weeks. After autophagy was confirmed by testing the expression of autophagy regulatory protein and autophagy key protein, autophagy PCR chip was used to determine the function of autophagy and the interaction with FoxO1, then the localization and expression of FoxO1 were tested. **RESULTS:** The lean body mass (LBM) (260.50±9.35 vs. 226.83±8.33), EDL wet weight (165.33±10.59 vs. 143.83±13.85) and FCSA (16.13±1.92 vs. 13.52±1.27), as well as the protein expression levels of Myosin (1 vs. 0.75±0.15) and Atrogin1 (1 vs. 1.29±0.22) in group H were significantly different from group C (P<0.05); The EDL wet weight (153.50±6.12) in group HR was significantly higher than group H, and Atrogin1 (0.73±0.14) expression was significantly decreased (P<0.05). The expression (11.26±4.72 vs. 83.72±13.82) and the nuclear localization of FoxO1 (56.28±3.47 vs. 65.39±4.29) was significantly increased (P<0.05) under hypoxia; The expression (12.83±4.95) and nuclear localization (52.82±5.32) of FoxO1 were decreased (P<0.05) in group HR. The expression of Beclin1 (1 vs. 1.27±0.11) and LC3II/I (1 vs. 1.44±0.14) was increased in group H; the expression of LC3II/I (1.23±0.08) was decreased in HR group. PCR microarray showed the number of differentially expression genes in autophagy was higher in group H than C, and the function was concentrated in “Genes involved in autophagic vacuole formation”; the number of autophagy genes was decreased in group HR/H, and the function was concentrated in “Co-regulators of autophagy and apoptosis”. The interaction and Pathway analysis between genes in group R/C, H/C, and HR/H and FoxO1, found that the regulation of autophagy by FoxO1 was concentrated in autophagy prophase. **CONCLUSIONS:** The alleviation of muscle atrophy by resistance training under hypoxia may be related to the regulation of autophagy by FoxO1. Supported by NNSF of China (31771317)

2792 Board #253 May 29 10:30 AM - 12:00 PM The Impact Of Three Consecutive Days Of Endurance Training In Hypoxia On Hepcidin Responses.

Daichi Sumi, Nanako Hayashi, Keiichi Yamaguchi, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.*

(No relevant relationships reported)

Endurance exercise in hypoxia resulted in similar hepcidin elevation compared with exercise in normoxia (Govus et al. 2014; Goto et al. 2017). However, how consecutive days of endurance training in hypoxia affects hepcidin elevation remains unclear. **PURPOSE:** The purpose of the present study was to determine the effect of three consecutive days of endurance training in hypoxia on hepcidin response. **METHODS:** Nine active healthy males completed two trials on different days, consisting of either three consecutive days of endurance training in hypoxia (F_{O₂}: 14.5%) or normoxia (F_{O₂}: 20.9%). They performed 90-min sessions of endurance training consisting of high-intensity endurance interval exercise (10 × 4 min pedaling at 80% of VO_{2max} with 2 min of active rest at 30% of VO_{2max}) followed by 30 min continuous pedaling at 60% of VO_{2max} during three consecutive days (days 1-3). Venous blood samples were collected after an overnight fast during experimental periods (days 1-4) to determine the serum hepcidin, iron, ferritin and haptoglobin concentrations. **RESULTS:** Pedaling workload during endurance training were significantly lower in the HYP (interval exercise: 166 ± 4.3 W) than in the NOR (194 ± 7.6 W, P < 0.0001). Serum iron (P < 0.0001) and ferritin (P = 0.005) concentrations on days 2-4 significantly increased in both trials, whereas there was no significant difference between the two trials. Serum haptoglobin concentrations did not significantly change throughout the experimental periods in either trial. Moreover, NOR showed significantly greater serum hepcidin elevation on the days 2-4 compared with day 1 (day1: 13.9 ± 8.6 ng/mL, day2: 30.4 ± 9.9 ng/mL, P = 0.004). However, no significant difference was observed in serum hepcidin concentrations between the NOR and HYP.

CONCLUSION: Three consecutive days of endurance training in hypoxia did not affect further hepcidin elevation compared with endurance training in normoxia.

Almost of endurance performance difference among athletes can be explained by running economy (RE). Short-term training under hypoxic conditions is useful in improving the RE; thus, enhancing endurance performance. However, the type of exercise intensity under hypoxic conditions effectively enhancing the RE and endurance performance has not been well documented. **PURPOSE:** We aimed to compare the changes in the RE and endurance performance between different exercise intensities by 5-day hypoxic training. **METHODS:** Twenty-two well-trained male distance runners were divided into these three training groups: low-intensity in normoxia (NOR, $FIO_2=20.9\%$), low-intensity in hypoxia (HL, $FIO_2=14.5\%$), and high-intensity in hypoxia (HH, $FIO_2=14.5\%$). They trained for five consecutive days (day 1-5), all groups performed short-time (5 rep*30 s) maximal sprint training in the morning, the NOR and the HL performed long-time low-intensity (2 rep*30 min at <4mM) endurance training and the HH performed long-time high-intensity (10 rep*2 min at 4mM) endurance training in the afternoon. Low-intensity (230 m/min) the RE (RE230), high-intensity (>4mM) the RE (RE4mM), and time-to-exhaustion at 100% of VO_{2max} intensity (TTE) on days 0, 8, and 14 were measured. **RESULTS:** A significant enhancement of the TTE and the RE230 was observed from day 0 to day 14 (267 ± 56 s to 374 ± 83 s and 0.99 ± 0.05 kcal/kg/km to 0.97 ± 0.06 kcal/kg/km; $P<0.05$); whereas, no significant enhancement of the RE4mM was observed (1.09 ± 0.08 kcal/kg/km to 1.08 ± 0.09 kcal/kg/km; $P>0.05$) in the HL. There was no significant enhancement of the TTE (443 ± 151 s to 513 ± 105 s; $P>0.05$), the RE230 (1.02 ± 0.03 kcal/kg/km to 1.01 ± 0.04 kcal/kg/km; $P>0.05$), and the RE4mM (1.18 ± 0.03 kcal/kg/km to 1.15 ± 0.05 kcal/kg/km; $P>0.05$) in the HH. Similarly, there was no significant enhancement of the TTE (432 ± 90 s to 393 ± 100 s; $P>0.05$), the RE230 (0.99 ± 0.06 kcal/kg/km to 0.99 ± 0.04 kcal/kg/km; $P>0.05$), and the RE4mM (1.10 ± 0.08 kcal/kg/km to 1.11 ± 0.06 kcal/kg/km; $P>0.05$) in the NOR. **CONCLUSION:** Our main finding was that the HL enhanced the RE at low-intensity and the TTE. However, the HH did not enhance the RE at high-intensity and TTE. These results indicate that increasing the exercise time than increasing exercise intensity is necessary to enhance endurance performance by hypoxic training.

EFFECTS OF 3-WEEK NATURAL ALTITUDE TRAINING ON IMMUNOGLOBULIN LEVELS IN AMATEUR ADOLESCENT ATHLETES
 Chunlong Gan, Fenglin Peng. Guangxi Normal University, Guilin, China.
 Email: ganchunlong@126.com
 (No relevant relationships reported)

PURPOSE: Although the effects of exercise on immunoglobulin have been widely studied in adults, the available evidence in children and adolescents exposed to high altitude environment is more sparse. To determine the effects of altitude training on IgA, IgM, IgG in amateur adolescent athletes.

METHODS: Twenty-one male amateur adolescent runners (age: 15.3 ± 0.7 years, height: 164.7 ± 5.4 cm, weight: 51.3 ± 6.1 kg, training period: 0.9 ± 0.2 years) in plain area (190m), with no previous altitude training experience, voluntarily participated in the study. All subjects were exposed to an altitude of 1890m (Liupanshui, China) for 3 week and altitude exposure consisted of 6 d/wk of training (4-5 h/d). The change of IgA, IgG, IgM were measured in the plain, and the first day, the first week, the second week, the third week after arrival at the high altitude research station.

RESULTS: The IgA level (2.13 ± 0.82 vs. 1.96 ± 0.74 , 2.00 ± 0.83 , 1.97 ± 0.79 , 1.99 ± 0.77 g/L, $p>0.05$) of the athletes decreased slightly in altitude environment, but there was no significant difference at different time. The IgG level of the athletes decreased slightly after arriving at the altitude (10.89 ± 1.98 vs. 10.53 ± 1.57 g/L, $p>0.05$), decreased significantly at the first weekend (10.89 ± 1.98 vs. 10.17 ± 2.25 g/L, $p<0.01$), began to rise in the second week, and was still significantly lower than the basic value at the third weekend (10.89 ± 1.98 vs. 10.38 ± 1.99 g/L, $p<0.01$). During the whole period of altitude training, the IgA level of the athletes was the lowest at the first weekend. The change of IgM level was similar to that of IgG, which decreased significantly at the first

weekend and was significantly lower than other time points (1.21 ± 0.46 vs. 1.19 ± 0.42 , 1.14 ± 0.41 , 1.23 ± 0.47 , 1.20 ± 0.44 g/L, $p<0.05$), and recovered to the basic value at the second and third weeks.

CONCLUSION: In the first week of high altitude, the level of immunoglobulin in amateur adolescent athletes will be significantly reduced, which suggests that the amateur adolescent athletes in the pursuit of high altitude training should pay attention to the monitoring and regulation of immunity function. IgG and IgM are more sensitive to hypoxia stimulation, and can be used as one of the sensitive indexes to monitor the immune function of the body during altitude training.

Typical acclimatization protocols for summiting Mt. Everest involve sleeping and hiking at successively higher altitudes for more than 45 days. Prolonged exposure to hypoxia on the mountain increases the risk for Acute Mountain Sickness, hypothermia, accidents and non-successful summits. Reducing the time of exposure could decrease this risk and improve summit success. **Purpose:** This study examined the efficacy of a pre-trip acclimation training protocol for completing a novel 14-day rapid ascent of Mt. Everest. **Methods:** This was a 12-week case study design examining nutrition, exercise training and hypoxia exposure from a single healthy experienced female mountaineer (Age 33 yrs) preparing to summit Mt. Everest. Pre-post measurements of body composition via DXA, heart rate (HR), SpO₂, sleep quality, hematology (hematocrit & hemoglobin), graded exercise test, and nutritional intake values were analyzed. **Results:** Simulated hypoxia gradually increased from 1800 to 5800 m over the 12 weeks (13.9 ± 0.9 hr/day). Over the 12 week protocol hypoxia tent HR increased from 52 to 64 bpm and SpO₂ decreased from 93 to 77%. Lake Louise AMS symptoms were mild at 0.5 ± 0.6 on a scale of 0-3. Blood Hb increased from 13.3 to 17.6 g/dl and Hct from 42.9 to 52.5% from baseline to summit day. Body mass (61.6 to 52.5 kg), body fat (26.6 to 15.3%), fat free mass (43.2 to 42.7 kg), and fat mass (16.4 to 8.1 kg) decreased over the 12 weeks. Fat utilization increased and carbohydrate utilization and blood lactate decreased across absolute workloads post-acclimation. Average daily energy intake was 1902 ± 18 kcals which consisted of 1.8 ± 0.3 CHO g/kg/day, 1.9 ± 0.2 FAT g/kg/day and 2.4 ± 0.2 PRO g/kg/day. In addition, 7 days of intermittent fasting during light exercise days (16-20 hrs) and 25 sessions of post-exercise 20-40 min sauna exposure occurred during the 12-week period. On May 10, 2019 (Day 1) the subject traveled from San Francisco to Everest Base Camp (5200m) (Day 2). The subject spent the next 7 days acclimatizing at altitudes of 5200-7500 m. On May 22, 2019 (Day 12) the subject successfully summited Mt. Everest (8848 m) and arrived back at the airport in Tibet on Day 13, arriving back in San Francisco on May 24th. **Conclusion:** A 12-week pre-acclimation protocol at sea level successfully prepared the subject to summit Mt. Everest in 14 days.

 (No relevant relationships reported)

Purpose: Strenuous exercise performed at altitude increases cardiac output and pulmonary arterial and capillary pressures to levels that may exceed a tolerable alveolar-capillary load, thereby evoking fluid leakage into the interstitial space. Accordingly, this study aimed to determine whether running an ultramarathon at moderate altitude increases extravascular lung water (EVLW) and whether this inhibits the transfer of gas across the alveolar-capillary membrane. **Methods:** Cardiac biomarkers (cTnI & BNP), exhaled nitric oxide (ExNO), echocardiographic signs of EVLW, and lung (DLco) and alveolar-capillary membrane (Dm) diffusing capacity for carbon monoxide (determined via a single-breath DLco/DLno method) were

assessed in 53 runners (10 Females; Age:41±10y BMI:23±2kg/m²) before, 1-4h and 24h after a 100km (CCC: 6,100m of ascent, altitude range of 1,035-2,584m) or 170km (UTMB: 10,000m of ascent, altitude range of 1,035-2,565m) mountain ultramarathon. **Results:** Participants finished the ultramarathon in 27±12h with an average heart rate of 124±13bpm. Cardiac biomarkers were increased acutely after the race (cTnl: 0.01±0.00 vs. 0.04±0.01ng/ml, p<0.01; BNP: 21±2 vs. 123±12pg/ml, p<0.01), while ExNO decreased (25.6±2.0 vs. 14.5±1.3 ppb, p<0.01). Signs of EVLW increased after the race (average comet tails count: 2±1 vs. 7±1, p<0.01) while DLco decreased (31.6±1.0 vs. 28.6±0.9 ml/min/mmHg, p<0.01) but Dm remained unchanged (171.4±7.6 vs. 167.2±8.8 ml/min/mmHg, p>0.05). Cardiac biomarkers, ExNO, EVLW and Dm were similar to baseline values after 24h of recovery, while DLco remained mildly reduced (30.6±1.6 ml/min/mmHg, p<0.05). **Conclusions:** These data suggest a mild and transient increase in cardiac biomarkers and extravascular lung water occur after completing an ultramarathon at moderate altitude, but this has minimal impact on the transfer of gas across the alveolar-capillary membrane, despite an overall reduction in lung diffusion. In some subjects an exaggerated increase in extravascular lung water and decrease in alveolar-capillary membrane diffusion was observed, suggesting that some individuals may have an increased propensity for developing mild exercise-induced pulmonary edema at altitude.

Resting And Exercising Heart Rates Increase With Acute Altitude Exposure In Sacred Valley, Peru
 Rhiannon M. Seneli. *St. Ambrose University, Davenport, IA.*
(No relevant relationships reported)

As one of the Seven Wonders of the World, Machu Picchu is a popular international destination. Being at high altitude and the physical demands of hiking in the region make acclimation to the change in altitude a challenge for individuals coming from low altitude. Understanding how individuals might respond to acclimation at various areas within the Sacred Valley region of Peru may be beneficial for electing specific logistics of a similar trip, particularly if physical exertion is planned. **PURPOSE:** To identify the changes in heart rate (HR) and blood pressure during acute exposure to altitude and acute acclimation. **METHODS:** Eight individuals (males = 3, 24.8 ± 5.4 years) living at low altitude recorded resting heart rate and blood pressure throughout the course of a 10-day trip in the Sacred Valley, Cusco, Peru. In addition, the subjects completed four Rockport Walk Tests (RWT): prior to travel (180 m), two moderate to high altitude locations (2792 and 3400 m), and return to low altitude (154 m). Repeated measures ANOVAs with post-hoc testing identified differences between RWT completion HR, time, and maximal oxygen estimation (VO_{2max}) and also between resting HR and blood pressure during 9 different altitude changes. **RESULTS:** The RWT had significant differences in estimated VO_{2max} estimations between 3400 m (45.7 ± 1.1 ml·kg⁻¹·min⁻¹) and return to low altitude (154 m, 49.1 ± 1.6 ml·kg⁻¹·min⁻¹, p = .03) and HR from the RWT had differences between both low altitude tests and high altitude tests (differences ranged from 29.6 - 34.7 bpm, p < .05). There were no differences in RWT completion time. Resting HR was the only resting measure to show changes and only after the highest ascent (4830 m) was HR increased (p < .05) from prior travel measures (180 m) (+28.4 ± 4.5 bpm), 2792 m (+30.4 ± 4.5 bpm), 4300 m (+18.1 ± 2.4 bpm), and return to low altitude (+27.0 ± 4.2 bpm). **CONCLUSION:** Both resting and exercising heart rates are affected by acute altitude exposure, despite several days of moderate to high altitude exposure. When planning trips to high altitude regions for short periods (≤ 10 days), elevated heart rates should be expected.

2798 Board #259 May 29 10:30 AM - 12:00 PM
Association between AMS Score, leg Muscle Strength And SpO₂ On One-day Rapid Ascent Of Mount Fuji
 Minoru Deguchi, Hiroki Honma, Mika Saito, Ayumu Kozuma, Yukina Mochizuki, Naoki Kikuchi. *Nippon Sport Science University, Tokyo, Japan.*
 Email: deguchi.minoru@icloud.com
(No relevant relationships reported)

Previous studies reported that mountain sickness in climbers is associated with heart rate, peripheral capillary oxygen saturation (SpO₂), and acute mountain sickness (AMS) score. These results supported the hypothesis that monitoring the SpO₂ can help prevent mountain sickness. In addition, because the muscle groups in the lower limbs are involved, it was hypothesized that the degree of fatigue during climbing, SpO₂, and leg muscle strength are related to blood circulation. **PURPOSE:** To examine the association between the AMS score, leg extension strength, and SpO₂ on a 1-day rapid ascent of Mount Fuji. **METHODS:** Sixteen subjects (10 male and 6 female, height: 168±8.1 cm, weight: 66.5±10.5 kg, age: 21±2.3 years) participated in the present study. Before and after climbing, the subjects underwent a leg extension strength analysis, and their heart rate and SpO₂ were measured using a pulse oximeter while climbing. To determine their AMS scores, we also conducted a questionnaire survey on the climbers' headaches, loss of appetite/nausea, fatigue/weakness, dizziness/lightheadedness, and sleep disorders. **RESULTS:** The average climbing time was 6 hours and 12 minutes to ascend and 2 hours and 57 minutes to descend Mount Fuji. All subjects with high AMS

scores tended to have low SpO₂ at the mountaintop. There was a positive correlation between leg muscle strength and SpO₂ at Mount Fuji's summit in male subjects, but not in females. In addition, there was no correlation between the AMS score and leg strength in both male and female subjects. **CONCLUSIONS:** Our results suggested that subjects with high AMS scores had low SpO₂ at the mountaintop. In addition, there is a positive correlation between leg muscle strength and SpO₂ at the mountain's summit in male subjects, but not in females.

Are There Differences In Oxygen Consumption Between A Breathing Restrictive Mask And Hypobaric Hypoxia?

Bryanne N. Bellovary, Andrew D. Wells, Zachary J. Fennel, Desmond J. Millender, Kelsey C. Bourbeau, Jonathan M. Houck, Christine M. Mermier. *University of New Mexico, Albuquerque, NM.* (Sponsor: Dr. Ann Gibson, FACSM)
 Email: bbellovary@unm.edu
(No relevant relationships reported)

PURPOSE: To determine the acute effects of a breathing restrictive mask (M) set to 2743 m (M only) during steady-state cycling compared with 1) wearing the mask set to 914 m at 1829 m of hypobaric hypoxia (H) (M+H combined = 2743 m) and 2) 2743 m of hypobaric hypoxia (H only) for subjects living at moderate altitude. **METHODS:** Nine subjects (5 males, 4 females; 25.9 ± 6.9 yr, 49.1 ± 7.1 ml · kg⁻¹ · min⁻¹) provided consent and completed four 1-hour sessions. Subjects completed a maximal oxygen consumption (VO_{2max}) cycling test to determine a 60% VO_{2max} workload at their altitude of residence Albuquerque's (~1570m). The following 3 sessions were randomized by condition: 1) M only, 2) M+H, and 3) H only. Sessions were separated by 48 hrs. After a warm-up, subjects cycled at 60% of their VO_{2max} workload for 20 min. Oxygen consumption was recorded every five minutes. Repeated measures ANOVA with Bonferroni's pairwise comparisons (p < 0.05) were applied to determine significant differences between the three conditions and if the three conditions' VO₂ differed from 60% of the baseline VO_{2max}. **RESULTS:** The average (±SD) VO₂ measured for the set workload (60% VO_{2max}) for each condition were: 29.6 ± 4.1, 34.3 ± 4.9, 31.4 ± 5.1, and 28.8 ± 4.5 ml · kg⁻¹ · min⁻¹ for baseline, H only, M+H, and M only, respectively. There was a main effect for condition between the 3 trials and the baseline 60% VO_{2max} workload, F_(3,21) = 6.20, p = 0.003. Compared to baseline 60% VO_{2max}, only H was significantly different (p = 0.022). Comparisons between the VO₂ for the three experimental conditions were significant (F_(2,14) = 8.714, p = 0.003) with H being higher than M (p = 0.028) and the other pairings being similar (p > 0.05). **CONCLUSION:** Individuals living at moderate altitude should use the 914 m mask setting rather than the 2743 m setting since the higher setting elicits a lower VO₂ at the same workload, thereby reducing the training stimulus. However, it is still best to use hypobaric hypoxia for training purposes as only H resulted in an increased VO₂ during exercise compared to baseline. Neither mask condition differed in submaximal VO₂ comparisons for the same workload at 1570m. This could explain why previous studies have not found post-training differences in VO_{2max} between control and mask groups.

2800 Board #261 May 29 10:30 AM - 12:00 PM
Transcriptional Activation Of Hypoxia Sensitive Genes Following Repeated Sprint Exercise In Hypoxia

Zachary McKenna, Roberto Nava, Zachary Fennel, Quint Berkemeier, Anna Welch, Christine Mermier. *University of New Mexico, Albuquerque, NM.* (Sponsor: Ann Gibson, FACSM)
(No relevant relationships reported)

Repeated sprint training in hypoxia (RSTH) utilizes short supramaximal efforts followed by incomplete rest intervals. RSTH has been shown to improve repeated sprint performance compared to repeated sprint training in normoxia. Because of the relatively short exposure to hypoxia compared to live high, train low approaches, the benefits of RSTH have been attributed to local muscular adaptations rather than hypoxia-induced erythropoiesis. Repeated activation of the hypoxia sensitive transcription factors HIF-1α and PGC-1α, and regulation of their gene targets related to angiogenesis (VEGF), mitophagy (BNIP3, PINK1), and glucose metabolism (PDK-M, GLUT4) may underlie these muscular adaptations. **PURPOSE:** To investigate the transcriptional activation of HIF-1α, PGC-1α and several HIF-1α-target genes following repeated sprint exercise in normoxia and hypoxia. **METHODS:** Eight recreationally active males (n=8) and one female (n=1) performed 20, 10s all-out sprints in normoxia (1600m) and hypobaric hypoxia (4600m) on a cycle ergometer on two days separated by 2 weeks. Skeletal muscle samples from the vastus lateralis were analyzed for mRNA levels of HIF-1α, PGC-1α, BNIP3, PINK1, VEGF, PDK-M, and GLUT4 pre, post and 3h post exercise in hypoxia and normoxia. Comparisons between condition and time were made using two-way repeated measures ANOVAs. **RESULTS:** There was a significant increase in mRNA levels for HIF-1α (fold change: 2.6±1.8) and VEGF (fold change: 3.0±1.6) 3h post-exercise in hypoxia (p<.05) but not normoxia. PGC-1α, was higher 3h post-exercise in both hypoxia (fold change: 9.2±4.6) and normoxia (fold change: 6.2±3.8; p<.05). No significant effect of time or group

was observed for BNIP3, PINK1, PDK-M, or GLUT4. **CONCLUSIONS:** Acute sprint exercise in both hypoxia and normoxia induces an increase in the transcription of PGC-1 α . However, hypoxia sensitive genes HIF-1 α and VEGF were only greater following sprint exercise in hypoxia. Collectively, these findings suggest that sprint exercise stimulates mitochondrial biogenesis, but an additional hypoxic stress is required to induce changes in hypoxia sensitive genes. The downstream effect of these transcriptional activations may increase angiogenesis and mitochondrial signaling in response to RSTH, which may in part explain the benefits of RSTH.

The Effect Of Elevation Training Mask On Skeletal Muscle Oxygenation During Walking

Melissa Puppa, Aaron Persinger, Alexis Nelson, Jay Hinton, Haley Fong, Douglas Powell, FACSM. *University of Memphis, MEMPHIS, TN.*

Email: melpuplash@gmail.com

(No relevant relationships reported)

Elevation training masks are commonly used to enhance training and performance. While these masks do not generate a hypoxic environment, they are used to train the respiratory system, a common limiting factor in performance in both trained and sedentary individuals. There is limited evidence as to how these masks affect respiration or skeletal muscle oxygenation. **PURPOSE:** The purpose of this study was to determine how resisted inspiration affects respiration and muscle oxygenation during walking. **METHODS:** 8 subjects between 18-35 years of age were recruited to walk at 1.6 m/s for 10 minutes with (RI) and without (CON) resisted inspiration. Masks were connected to the metabolic cart and a Moxy monitor was placed on the lateral head of the gastrocnemius to measure muscle oxygenation (SmO) throughout the duration of walking trials. The last 5 minutes of each condition were analyzed and presented as mean \pm SD. Student t-test was used to determine significance at $p < 0.05$. **RESULTS:** RI had no effect on VO₂ (CON: 14.17 \pm 0.96 RI: 14.23 \pm 2.94, $p=0.95$) or VCO₂ (CON: 13.02 \pm 0.89 RI: 13.18 \pm 2.61, $p=0.89$). RI caused an average increase of 4.9% in subjects heart rate and induced a significant decrease in respiration rate (CON: 25.93 \pm 1.59 RI: 18.63 \pm 3.84, $p=0.0006$). This coincided with no change in total hemoglobin (ThB) in the skeletal muscle (CON: 12.58 \pm 0.61 RI: 12.57 \pm 0.60, $p=0.98$) and an increase in 7 out of 8 subject's SmO with restricted breathing (CON: 41.94 \pm 20.15 RI: 48.52 \pm 23.08). Despite increased SmO, subjects reported a higher RPE in the RI condition. **CONCLUSIONS:** During walking, elevation training masks increase skeletal muscle oxygenation. This could be in part due to a longer inspiration allowing for improved blood oxygen saturated. An increased heart rate across most subjects despite no change in ThB could suggest a shift in the hemoglobin dissociation curve allowing more oxygen dissociation in the muscles. Future studies should examine the effect of elevation training masks on muscle oxygenation during higher intensity exercises.

Is Normobaric Hypoxia Effective For Sustaining Previously Acquired Altitude Acclimatization-induced Improvements In Mood State?

Emma Y. Atkinson, Ingrid V. Sils, Janet E. Staab, Charles S. Fulco, Allen Cymerman, Stephen R. Muza, FACSM, Beth A. Beidleman. *US Army Research Institute of Environmental Medicine, Natick, MA.* (Sponsor: Stephen R Muza, FACSM)

Email: emma.y.atkinson.ctr@mail.mil

(No relevant relationships reported)

PURPOSE: Mood state has been shown to improve with high altitude (HA) acclimatization to 4300 m. The purpose of this study was to determine if these acclimatization effects on mood state persist during reintroduction to 4300 m altitude (RA) after 12 days at sea level (SL) and whether or not normobaric hypoxia (NH) treatment is an effective countermeasure to prevent de-acclimatization. **METHODS:** Seventeen SL residents (age= 22 \pm 6 yr, weight= 75.2 \pm 13.3 kg; mean \pm SD) completed in the following order: 1) 4 days of baseline SL testing; 2) 12 days of HA acclimatization at 4300 m; 3) 12 days at SL post-HA acclimatization where each received either NH (n=9, FiO₂=0.122) or Sham treatment (n=8; FiO₂=0.207); and 4) 24-hour reintroduction to 4300 m altitude (RA) in a hypobaric chamber (460 Torr). Mood state was assessed using the Automated Neuropsychological Assessment Metrics Mood Scale (ANAM-MS), which includes the measurement of 7 mood dimensions: vigor, restlessness, depression, anger, fatigue, anxiety and happiness. The test was administered in the afternoon (~2-3pm) on 5 occasions at SL, once after 2h at HA (HA1), 20h at HA (HA2), 11 days at HA exposure (HA11), and following 4 h of RA (RA4). **RESULTS:** As there were no group differences between NH and Sham mood test scores at any of the time points, data were combined. Fatigue increased ($P < 0.05$) from SL (0.44 \pm 0.58) to HA1 (1.16 \pm 1.17) and HA2 (1.93 \pm 1.26) and then decreased ($P < 0.05$) from HA2 to HA11 (0.67 \pm 0.78) and remained low at RA4 (0.58 \pm 0.72). Vigor decreased ($P < 0.05$) from SL (2.80 \pm 1.42) to HA1 (1.54 \pm 1.19) and HA2 (1.33 \pm 1.31), and then remained unchanged ($P > 0.05$) from HA2 to HA11 (1.46 \pm 1.58), and

this effect persisted at RA4 (1.33 \pm 1.05). Anxiety increased ($P < 0.05$) from SL (0.17 \pm 0.31) to HA1 (0.49 \pm 0.97), decreased ($P < 0.05$) from HA1 to HA2 (0.07 \pm 0.17), remained unchanged from HA2 to HA11 (0.19 \pm 0.60), and remained low at RA4 (0.14 \pm 0.30). All other mood states remained unchanged from SL to HA and then HA. **CONCLUSION:** These results suggest that HA-induced improvements in mood state are retained during RA after 12 days at SL whether or not NH treatment is utilized. *Authors' view not official US Army or DOD policy. Funding USAMRDC.*

Serially-applied Ischemic Preconditioning Mediation Of Cardiopulmonary Compensations And Oxygen Kinetics During Exercise At Normobaric Hypoxia

Afton D. Seeley, Yihan Meng, Gregory Alvarado, Kevin A. Jacobs, FACSM. *University of Miami, Coral Gables, FL.*

(Sponsor: Kevin Jacobs, FACSM)

Email: ads129@miami.edu

(No relevant relationships reported)

INTRODUCTION: Ischemic preconditioning (IPC) involves brief, repetitive manually-imposed blood flow restriction of the limbs, capable of enhancing local blood flow and oxygen kinetics. As oxygen availability is of concern with increasing altitude, an evaluation of IPC's potential to influence physiological compensations is defensible. **PURPOSE:** To investigate the use of acute versus repeated IPC to influence cardiopulmonary compensation and oxygen kinetics during exercise performed at normobaric hypoxia (NH). **METHODS:** Six recreationally trained males (21 \pm 4 y, 178.6 \pm 4.4 cm, 81.1 \pm 13.0 kg, 15.0 \pm 5.6 % BF, VO_{2peak}: 43.6 \pm 4.7 mL \cdot kg⁻¹ \cdot min⁻¹ at 210 \pm 32 W) received 5-min of bilateral occlusion and reperfusion using automated cuffs (200 mmHg) placed on the upper thighs for a total of 40 min. This acute exposure (AI) was preceded by 45-min of passive recovery, 30-min of passive NH (14.2 \pm 0.1%) exposure, and six 6-min discontinuous exercise bouts (2 each at 40, 60, 80% NH PPO). To evaluate a potential dose-response relationship, the same subjects also completed a 7-day IPC (RI) procedure after a sufficient washout. Muscle oxygen saturation (SmO₂) was measured using a portable NIRS-based sensor placed over the vastus lateralis. Cardiac hemodynamics were measured continuously using impedance cardiography. Continuous ventilatory and metabolic data were collected using a metabolic cart. Superficial femoral artery volumetric flow was calculated using arterial diameter and velocity measures collected using a Doppler ultrasound. **RESULTS:** Both AI and RI elicited greater SmO₂ at supine rest (MD: 12.2 \pm 2.5%, $p = .004$; MD: 12.8 \pm 1.7%, $p = .001$) and seated rest (MD: 10.3 \pm 3.9%, $p = .045$; MD: 11.2 \pm 2.8%, $p = .010$) compared to a non-IPC NH procedure. At 80% NH PPO, AI and RI similarly attenuated decrement of SmO₂ compared to non-IPC NH (40.6 \pm 20 and 40.2 \pm 17.9 vs. 32.8 \pm 19.5%). Minute ventilation was also heightened following both IPC conditions at 80% compared to sham NH (106.4 \pm 17.3 and 106.5 \pm 10.9 vs 97.9 \pm 11.1 L \cdot min⁻¹), however neither were able to produce a meaningful change in peripheral oxygen saturation (83 \pm 4 and 84 \pm 3 vs. 84 \pm 4%). **CONCLUSIONS:** Preliminary data suggest that both acute and repeated IPC prior to exercise performed at NH may be capable of enhancing ventilation and subsequently working muscle oxygen saturation.

2804 Board #265 May 29 10:30 AM - 12:00 PM

Respiratory Muscle Training For Aerobic Endurance Performance At 3,658m Altitude

Courtney E. Wheelock¹, Hayden W. Hess¹, David Hostler, FACSM². ¹University at Buffalo, BUFFALO, NY. ²University at Buffalo, Buffalo, NY. (Sponsor: David Hostler, FACSM)

Email: cwheeloc@buffalo.edu

(No relevant relationships reported)

Increased ventilation is one effect of altitude hypoxia. This increases the work and energy cost of ventilation. Therefore, during sustained aerobic exercise this may lead to respiratory muscle fatigue and secondary locomotor muscle fatigue. **PURPOSE:** Determine if resistive or endurance respiratory muscle training (RRMT and ERMT, respectively) vs. sham RMT (SRMT) improves exercise performance during acute exposure at 3,658 m. We hypothesize that ERMT would augment time to exhaustion more than RRMT and SRMT. **METHODS:** Twenty-four subjects (age: 24 \pm 3 y; body fat: 16 \pm 6 %; VO_{2max}: 38 \pm 6 mL \cdot kg⁻¹ \cdot min⁻¹) cycled to exhaustion (55% VO_{2max}) in a hypobaric chamber at a 3,658 m before and after four weeks of respiratory muscle training (RMT). Prior to training, subjects completed a VO_{2max}, pulmonary function, and respiratory endurance tests (RET). Subjects were randomly assigned to SRMT (n=8), RRMT (n=8), or ERMT (n=8). All RMT consisted of three, 30-min training sessions per week for four weeks. The SRMT group completed a 5-sec inspiration, 5-sec breath hold, and 5-sec expiration every 30-sec. The RRMT group completed a maximal inspiration and expiration against 60% of maximal inspiratory (P_{imax}) and expiratory pressure (P_{Emax}) every 30-sec. The ERMT breathed into bag that maintained isocapnia continuously for 30 min (bag volume=55% vital capacity; breath frequency=0.6*maximal voluntary ventilation/bag volume). **RESULTS:** There were no differences in pre-RMT anthropometrics, pulmonary function, VO_{2max}, or cycle

time to exhaustion between groups (all $p > 0.05$). There were no changes in forced vital capacity after RMT ($p = 0.85$). The RRMT group increased P_{imax} and P_{Emax} after RMT ($p = 0.009$ and $p = 0.04$, respectively). The ERMT group increased RET after RMT ($p = 0.04$). There was no difference in $\dot{V}O_{2\text{max}}$ after RMT in any group. There was no difference in cycle time to exhaustion after RMT ($p = 0.14$) or between groups ($p = 0.4$). **CONCLUSIONS:** Four weeks of RRMT and ERMT training selectively improved pulmonary function tests. Both RRMT and ERMT improved cycle time to exhaustion at simulated 3,658 m (12,000 ft) altitude.

Measures Of Autonomic Cardiac Function Are Associated With Acute Mountain Sickness At High Altitude.

Elisabeth M. Board¹, Theocharis Ispoglou², Amanda Seims², Max Garrard², Lee Ingle³. ¹University of Sunderland, Sunderland, United Kingdom. ²Leeds Beckett University, Leeds, United Kingdom. ³University of Hull, Hull, United Kingdom.
 Email: lisa.board@sunderland.ac.uk
 (No relevant relationships reported)

Purpose: Evidence suggests acute mountain sickness (AMS) aligns to heart rate variability (HRV) suppression at high altitude. This study explored associations between measures of autonomic cardiac function and AMS scores in normobaric hypoxia (NH) and during ascent to very high altitude in the natural environment. **Methods:** Thirty participants (17 male and 13 female, aged 20-62 years) trekked from 2800m to 5350m (Himalaya, Nepal) over 14 days. Short term temporal and spectral measures of HRV were recorded at rest (paced breathing, 12 breaths per minute), in NH ($F_{I_2} = 0.124$, ~4100m) and in hypobaric hypoxia (HH) at 4356m and 5350m, during ascent. RMSSD and 60 second heart rate recovery (HRR60) following stepping exercise (3 min at 50-60% maximal aerobic capacity) were accepted measures of parasympathetic neural activity. The heart rate response (ΔHR) to an orthostatic postural challenge (two minutes supine followed by two minutes standing), reflective of sympathetic neural activity, was measured at the same time points ($\Delta HR = HR$ [peak stand] - HR [mean supine]). AMS diagnosis was confirmed for scores ≥ 5.0 (Lake Louise Survey, LLS) or ≥ 0.70 (Environmental Symptoms Questionnaire, ESQ-c) at least once during the ascent. Institutional ethical approval was gained. **Results:** Data analysis reflects 24 participants. Eleven (46%) developed AMS. Peak LLS AMS scores ranged between 1-5, 0-10 and 2-11 units in the AMS group at 2800m, 4356m and 5350m respectively, and 0-4 for the non-AMS group. No significant interaction ($P = 0.161$) nor a main effect for altitude ($P = 0.093$) was observed, however a significantly greater LLS score was observed in the AMS group at 5300m ($P < 0.001$). Peak LLS scores at 2800m correlated with RMSSD (NH) ($r = .483$, $P = .020$) and at 4300m correlated with RMSSD at 4300m ($r = -.487$, $P = .025$). Postural ΔHR at 2800m correlated significantly with the ESQ-c and peak LLS scores at 4300m ($r = -.601$, $P = .002$ and $r = -.579$, $P = .004$), and the ΔHR at 4300m correlated with ESQ-c and LLS scores at 4300m ($r = -.570$, $P = .005$ and $r = -.471$, $P = .023$). HRR60 (NH) correlated with LLS score at 4300 m and peak LLS score at this altitude ($r = -.495$, $P = .026$ and $r = -.450$, $P = .047$ respectively). **Conclusion:** AMS-susceptible individuals show vagal suppression at high altitude. Vagal measures may be useful indicators for AMS susceptibility at very high altitude.

Intra-individual Variability In The Acute Erythropoietic Response To Consecutive Hypoxic Exposures

Marissa Baranaukas¹, Joseph Powell², Alyce D. Fly¹, Bruce J. Martin¹, Timothy D. Mickleborough¹, Robert F. Chapman, FACSM¹. ¹Indiana University, Bloomington, IN. ²Case Western Reserve University, Cleveland, OH.
 Email: marbaran@indiana.edu
 (No relevant relationships reported)

PURPOSE: Altitude training has become a standard strategy used by athletes to legitimately increase hemoglobin mass and induce favorable changes in sea-level endurance performance. While the acute erythropoietic response to a fixed level of hypoxia (altitude) varies considerably between individuals, it is generally assumed there is consistency within an individual for repeated exposures. Therefore, we aimed to document within-subject variation in the acute erythropoietic response to consecutive exposures to a fixed-level of continuous normobaric hypoxia. **METHODS:** Seven subjects (men $n = 4$, women $n = 3$) completed three exposures to 12hr of continuous normobaric hypoxia simulating an altitude of 3,000m/9,900ft ($F_{I_2} = 0.14$), with each exposure separated by 28 to 56 days. Each visit was performed at the same time of day, with close controls placed on hydration and environmental conditions. Serum concentrations of erythropoietin (EPO) were measured at baseline prior to hypoxic exposure (0hr), and then following 6hr, and 12hr spent in continuous hypoxia. The relative change in serum EPO was taken as the percentage

difference from 0hr to 6hr (ΔEPO_{0-6}) and 0hr to 12hr (ΔEPO_{0-12}). A two-way repeated measures ANOVA was used to evaluate the effects of hypoxic exposure time on EPO concentrations.

RESULTS: Twelve hours of continuous hypoxic exposure had a significant effect on the EPO response ($P < 0.001$), with serum concentrations increasing by an average of $+55 \pm 33\%$ (range: 14-110%) after 6hr and $+83 \pm 33\%$ (range: 31-125%) after 12hr compared to baseline. Within individuals, ΔEPO_{0-6} varied by $33 \pm 23\%$ (range: 4-77%) and ΔEPO_{0-12} by $58 \pm 28\%$ (range: 4-90%) between consecutive hypoxic exposures. **CONCLUSIONS:** Practically, our data demonstrate that athletes traveling to altitude training camps may not have a consistent hematological response given the wide intra-individual variability observed in serum EPO concentrations to repeated fixed hypoxic doses.

Magnitude Of Deacclimatization From Moderate Altitude Following Three Days At Sea Level

Elizabeth A. Gideon¹, Catherine L. Coriell¹, Natalia Correa¹, Arianna R. Strick¹, Daniel A. Lord¹, Robert F. Chapman, FACSM², Joseph W. Duke¹. ¹Northern Arizona University, Flagstaff, AZ. ²Indiana University, Bloomington, IN.
 (No relevant relationships reported)

Chronic hypoxia elicits a multitude of physiologic responses leading to an increase in total hemoglobin mass (THM), an enhanced hypoxic ventilatory response (HVR), and many more. The magnitude of the acclimatization observed in these parameters is hypoxia dose-dependent, with changes at moderate altitude being less than at high altitude. Accordingly, high altitude has been the largest focus in this area with much less attention on moderate altitude, particularly as it pertains to deacclimatization. This is relevant as many more people reside at moderate altitude permanently or for weeks/months at a time for training, deployment, or recreation. These individuals will inevitably visit sea level (SL) for a short period of time for leave, competition, or leisure and then return to moderate altitude. It is not known how much, if any, deacclimatization in THM or HVR occurs when fully acclimatized individuals travel to SL for 3 days.

Purpose: Test the hypothesis that following 3 days at SL THM will be significantly altered and HVR will remain unchanged.

Methods: To Date, seven healthy participants (22.1 ± 1.1 years, 5 females) have completed the study. All visits (6 total) were conducted in Flagstaff, AZ (altitude 2,100m). Three visits prior to descent to, and 66.3 ± 1.5 hours in, Phoenix, AZ (altitude 330m) and three upon return from SL. Visit 1 included consent and screening. In 4 visits, THM was quantified using the optimized carbon monoxide rebreathing technique and poikilocapnic HVR was determined using a step-down decrease in inspired oxygen fraction from 0.21 to 0.09. Pre-SL measurements were averaged and used to compare to post-SL measurements. A one-way ANOVA was computed on THM and HVR between pre- and post-SL measurements using GraphPad Prism. Significance was set at $p = 0.05$.

Results: At present, we have found no significant effect on THM ($p = 0.07$). HVR was unchanged from pre- to post-SL ($p = 0.49$).

Conclusion: Following three days at SL, THM and HVR were unchanged. Our data suggest that 3 days at SL may not be sufficient to significantly alter HVR or THM. However, THM did decrease by 5% post-SL ($p = 0.07$) so a greater sample size may alter our findings.

2808 Board #269 May 29 10:30 AM - 12:00 PM
Hypoxia-induced Increase Of Heartrate Is Attenuated In Endurance Trained Men

Gunnar Treff¹, Mahdi Sareban², Franziska Macholz², Larissa Schäfer², Lisa M. Schiefer², Jürgen M. Steinacker, FACSM¹, Marc M. Berger². ¹University of Ulm, Ulm, Germany. ²Paracelsus Medical University Salzburg, Salzburg, Austria.
 Email: gunnar.treff@uni-ulm.de
 (No relevant relationships reported)

PURPOSE: To study differences of the cardiovascular response to acute hypobaric hypoxia between endurance trained (ET) and untrained (UT) healthy men.

METHODS: After at least 10 min of rest, heart rate (HR), pulmonary blood flow (PBF), and mean arterial blood pressure (MAP) were assessed at baseline in normoxia (424 m) in 19 ET and 19 UT ($\dot{V}O_{2\text{max}} 66.3 \pm 5.7$ vs. 44.8 ± 7.1 mL/min/kg, $p < .001$; body mass 71 ± 7 vs. 80 ± 8 kg, $p < .001$; age 31 ± 7 vs. 38 ± 9 years; $p < .006$; mean \pm sd). Afterwards, participants were transported by train from 750 m to 3450 m within 2 h. All measurements were repeated 3 h, 24 h, and 48 h after ascent. HR was measured via pulse-oximetry and PBF by inert gas rebreathing (Innocor, Innovision, DK). Stroke volume (SV) was calculated as PBF/HR. MAP was measured via auscultatory method in a seating position. To analyze differences between groups (UT vs. ET), between timepoints of measurements in norm- and hypoxic conditions, and interactions

between time and group, a mixed model (MM) was calculated. Differences within groups between baseline and particular timepoints in hypoxia were calculated with paired t-tests (TT).

RESULTS: All variables except of MAP changed significantly over time ($p_{MM} \leq .006$), but only for HR the time course was different between ET and UT (group*time: $p_{MM} = .023$). This was due to an attenuated HR-increase in ET (8%; $p_{TT} = .008$) after 3 h in hypoxia being half as high than in UT (16%; $p_{TT} = .000$). At the same timepoint, average SV remained stable in ET (+2%; $p_{TT} = .570$), but tended to decline in UT (-7%; $p_{TT} = .137$). Consequently, PBF increased by 11% after 3 h at high altitude in both ET and UT ($p_{TT} = .010$ and $.027$) without being different between groups at any timepoint ($p_{MM} = .117$).

CONCLUSIONS: While cardiovascular response to hypoxia was generally similar, ET showed an attenuated increase in HR after initial exposure to hypoxia. The HR attenuation might be attributable to a higher parasympathetic activity in ET that has been documented before and is a general characteristic of ET.

2809 Board #270 May 29 10:30 AM - 12:00 PM
Relationships Between Ventilatory And Heart Rate Responses To Hypobaric Hypoxia: Influences Of Acetazolamide

Audrey Johnson, Aaron Caldwell, Karleigh Bradbury, Beau Yurkevicius, Kirsten Coffman, Roy Salgado, Nisha Charkoudian, FACSM. *USARIEM, Natick, MA.* (Sponsor: Nisha Charkoudian, FACSM)

(No relevant relationships reported)

Acetazolamide (AZ) is often used for prevention and/or treatment of acute mountain sickness (AMS), particularly during rapid ascent to altitudes > 3000 m. Although it is known that AZ augments ventilation (V_E), it is unclear how this may affect chemoreflex relationships among ventilatory variables and control of heart rate (HR).

PURPOSE: The purpose of the study was two-fold: 1) establish the effect of AZ and hypobaric hypoxia (HH) on V_E and HR; and 2) estimate the effect of AZ on the chemoreflex relationship between V_E and HR.

METHODS: After completing familiarization testing at sea level (SL), 10 male volunteers (22 ± 3 yr; height: 176.0 ± 7.1 cm; weight: 77.5 ± 11.5 kg) completed two 30 hr HH exposures (~3500 m); one while taking AZ (500 mg/day) and one while taking a placebo, in a single-blind crossover design in random order. Ventilation and gas exchange, including HR, V_E , and end-tidal partial pressure of carbon dioxide (P_{etCO_2}), were measured three times at rest, once at SL and then at ~2 and 24 hours into exposure to simulated altitude. A linear mixed model with a random intercept per subject was utilized to evaluate the influences of AZ and HH on HR, V_E , and P_{etCO_2} .

RESULTS: V_E increased and P_{etCO_2} decreased ($p < 0.05$ for all) with both HH and AZ. HR increased with HH ($p < 0.001$), but there was no further effect of AZ ($p = 0.15$). HR was related to both V_E ($p = 0.009$) and P_{etCO_2} ($p < 0.001$) in all subjects. AZ shifted the relationships between HR, V_E , and P_{etCO_2} , but there was no interaction between AZ and HH ($p > 0.10$ for both). Overall, while AZ augmented V_E it did not affect the slope of the relationship between HR and V_E , but rather shifted the relationship to lower V_E values.

CONCLUSION: During exposure to HH, activation of the chemoreflex augments both ventilation and sympathetic outflow to the heart causing increased HR. Our present findings that V_E tended to be lower for a given level of HR during AZ trials, suggest that AZ may have an influence to shift the relationship between these two chemoreflex-mediated events.

The Effects Of Exercise Training In Hyperoxia Compared To Normoxia On Cardiorespiratory Fitness: A Meta-analysis

Nils Freitag¹, Kenji Doma², Sulin Cheng³, Wilhelm Bloch¹, Moritz Schumann¹. ¹German Sport University, Cologne, Germany. ²James Cook University, Townsville, Australia. ³Jiao Tong University, Shanghai, China. (Sponsor: Heikki Kyröläinen, FACSM)

Email: n.freitag@dshs-koeln.de

(No relevant relationships reported)

PURPOSE: Previous studies have indicated that supplemental oxygen (i.e. hyperoxia) may acutely enhance exercise performance, providing benefits for patients with limited physical capacity. However, the evidence for superior long-term adaptations of regular hyperoxic exercise in clinical populations is limited. Therefore, this systematic review and meta-analysis aimed to evaluate the effects of chronic exercise in hyperoxia compared to normoxia in patients diagnosed with chronic diseases.

METHODS: Databases were systematically searched for randomized controlled trials in accordance with PRISMA until May 20th, 2019. Eligibility criteria included adult patients with various chronic diseases (i.e. cardiovascular, pulmonary, neurological, metabolic, musculoskeletal or cancer) engaging in regular supervised exercise training

in hyperoxia compared to an exercising normoxic control group. The outcome of interest included maximal power output (PO), peak oxygen consumption (VO_{2peak}) and maximal distance in the 6-minute walk test (6MWD). Standardized mean differences (SMD) were calculated and a random-effects model was used to pool effect sizes using R (3.6.1). **RESULTS:** Out of the identified 4038 studies, 11 articles were deemed eligible. A total of 132 patients (64.3 ± 3.2 yrs., 36% women) and 131 patients (64.9 ± 3.6 yrs., 33% women) were included in hyperoxia and normoxia groups, respectively. The majority of patients were diagnosed with chronic obstructive pulmonary disease (COPD, 94.1%) while 18 patients were diagnosed with coronary artery disease. The average duration of interventions was 8.9 ± 5.1 weeks. The observed effects for PO (SMD -0.33; 95% CI -0.67, 0.01; $p = 0.06$), VO_{2peak} (SMD -0.24; 95% CI -0.54, 0.05; $p = 0.11$) and 6MWD (SMD -0.21; 95% CI -0.78, 0.36; $p = 0.46$) showed no statistical significant difference between the two conditions. **CONCLUSION:** There is no evidence for beneficial chronic adaptations in cardiorespiratory fitness, when exercise is performed in hyperoxia. However, the studies to date have only examined patients diagnosed with COPD and coronary artery disease. Future studies should identify the optimal dose-response mechanisms to bridge the gap between acute responses and chronic adaptations in hyperoxic exercise.

Effect Of Acetazolamide Versus Heat Acclimation On Oxygen Saturation During Sleep At Altitude

Dina M. Pitsas, Aaron R. Caldwell, Beau R. Yurkevicius, Karleigh E. Bradbury, Nisha Charkoudian, FACSM, Roy M. Salgado. *United States Army Research Institute of Environmental Medicine, Natick, MA.*

(No relevant relationships reported)

Reduced oxygen at high altitude can alter breathing at night which can disrupt sleep. Acetazolamide (AZ) has been shown to augment breathing and oxygen saturation (SpO_2) during sleep. However, it is unclear whether heat acclimation (HA), which has been suggested to have beneficial effects in hypoxia, may provide benefits similar to AZ. **PURPOSE:** To determine if there is a difference in average SpO_2 ($avgO_2$), time below 88% SpO_2 (T_{BL88}), and average pulse rate (PR) between treatments with AZ versus HA. **METHODS:** Seventeen unacclimated healthy men (age: 22 ± 4 years; mass: 75 ± 12 kg; height: 172 ± 8 cm; body fat: $22 \pm 6\%$) participated in at least one of two ($N = 6$ completed both) 30-hour altitude studies: Study 1) AZ (250 mg twice/day for three days) vs placebo or Study 2) pre-HA altitude exposure, followed by an 8-day exercise-HA protocol (treadmill walking: 120 min, 3.1 mph 2% grade, 40°C, 40% RH), and then a post-HA altitude exposure. Both studies were identical in regards to altitude (3,500 m), ascent rate, exposure time, and sleep assessment. For analysis, PL and pre-HA acted as the control conditions (CON) and AZ and post-HA as the experimental conditions (EXP). $avgO_2$, T_{BL88} , and average PR were recorded during sleep via wrist pulse oximeter. A linear mixed model with subjects as a random effect was used to compare treatments (AZ and HA), and conditions (CON and EXP) with total sleep time as a covariate for T_{BL88} . **RESULTS:** There was a significant interaction between the condition and treatment-type for $avgO_2$ ($p < .001$) and T_{BL88} ($p < .001$) during sleep, but no interaction was found for average PR ($p = .49$). Pairwise comparisons were performed for the former two variables within each study treatment. $avgO_2$ was greater in the AZ treatment (difference = 5.7%; 95% C.I. [4.2, 7.2]), and a non-significant increase in $avgO_2$ was found post-HA (difference = 0.9%; 95% C.I. [-0.3, 2.2]). Additionally, T_{BL88} was reduced in the AZ treatment (difference = -207.7 min; 95% C.I. [-283.2, -132.2]), while there was a non-significant increase in T_{BL88} post-HA. PR was higher in CON (72 bpm) than EXP (69 bpm). **CONCLUSION:** Our data confirms AZ increases SpO_2 during sleep at altitude, however, we were unable to observe a similar improvement in oxygen saturation after HA.

Flow Mediated Vasodilation In Response To 3-Weeks Of Moderate Altitude Exposure

Eve M. Edwards, Lauren N. Manuzak, Sara S. Jarvis. *Northern Arizona University, Flagstaff, AZ.*

(No relevant relationships reported)

The effects of moderate altitude on the cardiovascular system is an extensively researched subject, but no definitive timeline regarding the vascular acclimatization for flow mediated vasodilation (FMD) measurements is currently available in the scientific literature. It has been suggested that 3 wks might be sufficient (Frick et al., 2006).

However, if this amount of time is not sufficient it will complicate data interpretation. **PURPOSE:** To assess the timeline of acclimatization to moderate altitude (2,130 m), specific to FMD in healthy young males. **METHODS:** After spending ≥ 4 weeks at lower altitude (331-1,197 m), 5 male subjects (18.6 ± 1 yr; 71.8 ± 8.7 kg; 1.8 ± 0.04 m; 22.8 ± 1.9 kg/m²) were tested within 1 wk ± 1 day of arrival to moderate altitude (V1) and were tested again at 2 wks (V2) and 3 wks (V3) after their initial arrival. Heart rate (HR), blood pressure (BP; systolic, SBP; diastolic, DBP), and brachial artery diameter were measured (using Brachial Analyzer) during baseline (BL) and after 5

min of forearm cuff occlusion (250 mmHg). FMD was assessed as the percent increase in diameter after the cuff occlusion. **RESULTS:** When comparing V1, V2, and V3, HR was no different between the visits (63±10 vs. 57±11 vs. 64±20 bpm; p=0.52 for V1 vs. V2 vs. V3, respectively). SBP was significantly higher in V1 compared to V2 and V3 (116±6 vs. 106±11 vs. 106 ±12 mmHg; both p<0.05). DBP was no different (63±9 vs. 57±9 vs. 59±6 mmHg; p=0.43). BL diameter was also not different between the visits (8.1±1.5 vs. 7.5±1.5 vs. 7.5±1.2 mm; p=0.69). FMD showed a trend toward a difference between the three visits (5.1±1.1 vs. 6.5±1.6 vs. 5.0±1.5%; p=0.07).

CONCLUSION: After 3 wks of exposure to moderate altitude, it appears that FMD may continue to fluctuate. This suggests that additional measurements beyond 3 wks should be obtained to determine a better timeline for when vascular acclimatization has been achieved. This will allow better guidance for FMD measurements obtained in subjects at altitude.

3 Weeks Hypoxic Training Improves Pwv, No, Angiotensin II And Endothelin In Acute Hypoxic Exposure

Xiaolin Yang¹, Yawei Xing², Yang Hu¹, Yanchun Li¹, Tao Mei¹.
¹Beijing Sport University, Beijing, China. ²Beijing Traffic Management Bureau, Beijing, China.
 Email: yxl_lyn@163.com
 (No relevant relationships reported)

PURPOSE: To observe the acute hypoxic responses when the subjects exposed to a normobaric hypoxic environment and acute hypoxic exercise (4800m), and analyze the improvement of acute hypoxic response after 3 weeks hypoxic training. **METHODS:** Male subjects (N=53, 20.64±1.39 years) were trained four times per week in a normobaric hypoxic environment for three weeks (1st week: 2500m, 2nd week: 3500m, 3rd week: 4500m). Daily training session included 30 min cycling, 30 min rest, 30 min running and 30 min rest. Individual exercise intensity kept in moderate at SpO₂. Resting BP, PWV, plasma NO, AngII and ET in normoxia(NOR) and acute hypoxia (HYP) were measured at the baseline. BP and PWV were measured before and immediately after the 20min cycling with constant load 80W (60rpm) both at the NOR and HYP conditions. All tests were measured again after 3 weeks hypoxic training. Pre- and post- data were analyzed by paired-samples T test. **RESULTS:** 1) At the first hypoxic exposure, DBP significantly decreased (68.6±10.5 vs. 74.0±8.0, mmHg, p<0.05), and plasma NO (57.7±13.5 vs. 66.1±14.2, umol/L, p<0.05) and AngII(101.6±28.1 vs. 116.3±31.2, pg/ml, p<0.01) significantly decreased. SBP increased while DBP decrease immediately after 20min cycling in NOR compared with HYP (SBP: 157.7±18.2 vs.167.9±21.6,mmHg, p<0.05; DBP: 76.5±8.8 vs. 70.7±7.5,mmHg, p<0.05).2) After 3 weeks training, RbaPWV and LbaPWV in HYP significantly decreased (RbaPWV:1292.9±155.7 vs. 1407.9±218.5, cm/s, p<0.05; LbaPWV: 1307.3±166.6 vs. 1387.9±219.3, cm/s, p<0.05), NO(56.6±11.6 vs. 66.1±14.2, umol/L, p<0.05) and AngII(103.3±18.7 vs. 116.3±31.2, pg/ml, p<0.05) in NOR was decreased, however AngII(117.1±23.2 vs. 103.3±18.7, pg/ml, p<0.05) and ET(132.9±29.9 vs. 114.4±31.9, umol/L, p<0.05) increased when exposure in HYP compared with NOR.**CONCLUSIONS:** 3 weeks hypoxic training improved vascular responses, relieved adverse reactions of hematologic system in acute hypoxic exposure.

Increased Oxyhemoglobin Binding Affinity Improves Cerebrovascular Responses To Hypoxia In Sprague-Dawley Rats

Brian T. Williams¹, W. Rainey Johnson¹, Geoffrey E. Ciarlone¹, Chelsea N. Willoughby¹, Hanbing Zhou², Richard T. Mahon².
¹Naval Medical Research Center, Silver Spring, MD. ²The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, MD.
 (No relevant relationships reported)

PURPOSE: This study evaluated the effect of increased oxyhemoglobin (O-H) affinity on cerebrovascular response to normobaric hypoxia.

METHODS: Cerebrovascular response was assessed in 18 mechanically-ventilated Sprague-Dawley rats during acute exposure to normobaric hyperoxia (FiO₂ 1.0), normoxic air (FiO₂ 0.21), and hypoxic air (FiO₂ 0.10). Prior to exposure, the rats were administered GBT-1118 (GBT, 100mg/kg) or normal saline via oral gavage. Pial microcirculation was assessed and quantified through a cranial window created in the parietal bone of anesthetized rats. Cardiopulmonary parameters were measured throughout the exposures. Oxyhemoglobin binding affinity (p50) was assessed following the final gas exposure using a Hemox Analyzer.

RESULTS: The mean p50 of GBT- and saline-treated animals was 31.46 and 37.63, respectively, demonstrating increased O-H affinity with GBT (p=0.0017). During steady state normoxia (FiO₂ 0.21), mean pial artery diameter decreased from baseline (FiO₂ 1.0) by 0.26% in saline animals compared to a 3.99% increase in GBT animals (p=0.1807). Additionally, GBT-treated animals demonstrated an 11.7% increase in blood O₂ saturation (p<0.0001), an 11.4% increase in peak CO₂ (p=0.0692), and an 8% increase in heart rate (HR) (p=0.015) compared to saline controls. During steady state hypoxia (FiO₂ 0.10), mean pial artery diameter decreased from baseline by 23.83% in saline animals compared to a 3.78% increase in GBT animals (p<0.0001). Additionally, GBT-treated animals demonstrated an 11.4% increase in blood O₂ saturation (p=0.012), a 14.1% increase in peak CO₂ (p=0.074), and a 9.3% decrease in HR (p=0.018) compared to saline controls.

CONCLUSIONS: Collectively, the data show that impairments in cerebrovascular and cardiopulmonary function resulting from exposure to severe hypoxia can be mitigated through increased O-H binding and subsequent increases in blood oxygenation.

Mood State Is Related To Acute Mountain Sickness At Both 3000m And 4050m Altitude

Peter S. Figueiredo, Ingrid V. Sils, Janet E. Staab, Charles S. Fulco, Stephen R. Muza, FACSM, Beth A. Beidleman, USARIEM, Natick, MA. (Sponsor: Stephen Muza, FACSM)
 (No relevant relationships reported)

PURPOSE: The purpose of this study was to further explicate the relationship between changes in mood states, assessed using the Automated Neuropsychological Assessment Metrics Mood Scale (ANAM-MS), and severity of acute mountain sickness (AMS) without the confounding factors of acetazolamide, climbing rate and environmental conditions.

METHODS: Nineteen healthy lowlanders (16 men, 3 women; mean±SE; 22 ±1yr, 76.6 ±3.1 kg, 173.2 ±2.1cm, 46.0 ±1.2 ml · kg⁻¹ · min⁻¹) were randomly exposed to either 3000m (526mmHg) or 4050m (460mmHg) in a hypobaric chamber for 20h. Seven mood states (anger, anxiety, happiness, fatigue, depression, restlessness, and vigor) were assessed using the ANAM-MS; a series of 42 questions answered on a 0-6 Likert Scale. AMS severity was assessed using the AMC-Cerebral Factor Score (AMS-C) of the Environmental Symptoms Questionnaire. Both tests were administered on 8 occasions at sea level (SL), and after 2h and 20h at each altitude (HA2 and HA20). The SL baseline scores for ANAM-MS and AMS-C were calculated as the mean of the 7th (morning) and 8th (afternoon) assessments.

RESULTS: There were no differences between altitude groups in mood at SL, HA2 or HA20 so data were combined. There was differences between altitude groups in AMS-C score so data was analyzed separately. No mood state changed significantly from SL to HA2. However, fatigue and restlessness increased (P<0.05) from SL (0.57 ±0.13; 0.07 ±0.03) to HA20 (1.41 ±0.32; 0.52 ±0.20), respectively. In addition, vigor decreased (P<0.05) from SL (1.97 ±0.30) to HA20 (0.88 ±0.21). Happiness, anxiety, depression and anger did not change over time. AMS-C was elevated (P<0.05) at 4050m (1.82 ±0.27) compared to 3000m (0.22 ±0.29) at HA20. Restlessness (r=0.66; P=0.037) and anxiety (r=0.65; P=0.044) correlated with AMS-C at HA20 in the 4050m group. Fatigue (r=0.77; P<0.016) and anger (r=0.95; P=0.0001) correlated with AMS-C at HA20 in the 3000m group.

CONCLUSION: ANAM-MS ratings of fatigue, restlessness and decreased vigor emerge as low as 3000m due to hypobaric hypoxia alone. Mood disturbances were related to AMS severity; subjects with the highest ratings of fatigue and anger at 3000m, and restlessness and anxiety at 4050m possessed the highest AMS-C scores in their respective groups. *Authors' views not official U.S. Army or DoD policy. Scientific Abstract

While spaceflight-associated neuro-ocular syndrome (SANS) related to intracranial hypertension (IH) is considered NASA's top health risk for long-duration spaceflight, the underlying mechanisms remain unclear. **PURPOSE:** To examine if repeated bouts of micro- and hypergravity during parabolic flight (PF) would increase blood-brain barrier (BBB) permeability subsequent to the combined effects of cerebral hyperperfusion (hemodynamic) and systemic oxidative-nitrosative (molecular) stress. **METHODS:** Six participants (5♂, 1♀) aged 29 ± 11 years were examined before, during and after PF. Six gender and age-matched (27 ± 6 years) controls were subject to the same procedures/experimental timeline with the exception of PF. Duplex ultrasound was employed to measure blood flow in the anterior (internal carotid artery, ICA) and posterior (vertebral artery, VA) circulation, with venous blood assayed for biomarkers specific to oxidative-nitrosative stress (electron paramagnetic resonance spectroscopy/ozone-based chemiluminescence) and structural integrity of the neurovascular unit (NVU, chemiluminescence/ELISA). **RESULTS:** PF was associated with a selective increase in VA flow during the most marked gravitational transition from micro- to hypergravity ($P < 0.05$). Increases in oxidative-nitrosative stress, gliovascular GFAP and S100 β were observed after PF ($P > 0.05$), the latter proportional to the increase in VA flow, whereas biomarkers of neuronal-axonal damage (neuron-specific enolase, neurofilament light-chain, ubiquitin carboxy-terminal hydrolase L1 and tau) remained stable ($P > 0.05$). **CONCLUSION:** Collectively, these data are the first to demonstrate that acute gravitational transitions result in minor BBB disruption due to the combined effects of hemodynamic-molecular stress thereby proposing an alternative candidate mechanism and biomarkers for the reported neurological sequelae underlying SANS.

The microgravity environment can have detrimental impacts on human health. Muscle atrophy, declines in bone mass, wedging of vertebral bodies, loss of normal spinal curvature, and decreased functional capacity are all consequences of prolonged microgravity exposure. Atrophy of the muscles along, and around, the spine is one of the primary contributors to the development of low back pain in space. **PURPOSE:** To design and fabricate a low-cost, diurnally worn upper-body garment with integrated neuromuscular electrical stimulation to prevent and mitigate low back pain in astronauts. **METHODS:** A custom fitted, upper-body garment that contained a neuromuscular electrical stimulation system was originally designed in modeling software (Solidworks Premium 2018, Waltham, MA). The garment was fabricated using highly durable, anti-microbial material (88.7% polyester, 8.6% lycra, 2.7% silver ion fiber). An elastic belt for additional compression to maximize contact between skin and electrodes was also incorporated. Four hydrogel electrodes were placed over motor points of the erector spinae and multifidus musculature. The wireless electrodes sent signals to a controller, all of which were integrated into the garment. A frequency of 50 Hz, pulse width of 200 μ s, amplitude of 14 to 21 mA, and an on/off time of 20 sec was used during testing. Four participants with low back pain wore the garment and recorded pain levels, via a visual analog scale, at strategic times before and after

the performance of the following exercises in our laboratory: isometric base, I's, T's, and Y's, shoulder adduction and flexion, hamstring curls, inverted rows, pull-ups, and seated wood choppers. A Friedman's ANOVA was used to test for differences in subjective pain measures with a significance of 0.05. **RESULTS:** No differences in pain were found at baseline (4.5 ± 0.6) when compared to pain following an exercise bout immediately after baseline (5.0 ± 0.8), after 8 hours of continuous wear (3.3 ± 1.5), and immediately following the exercise bout after this 8-hour timepoint (3.3 ± 1.5 ; $p = 0.112$). **CONCLUSION:** Further testing is needed to determine if the integration of neuromuscular electrical stimulation into a diurnally worn upper-body garment may mitigate atrophy of the erector spinae and multifidus muscles, resulting in decreased low back pain.

Email: simone.porcelli@itb.cnr.it

(No relevant relationships reported)

Purpose: Prolonged periods of bed-rest (BR), experimental simulation of microgravity, greatly affect oxidative metabolism by acting at several levels of the O₂ pathway. Short duration (10 days) of horizontal BR negatively affects in-vivo functional biomarkers related to skeletal muscle oxidative metabolism without affecting mitochondrial respiration ex-vivo. The impairment of muscle oxidative metabolism can partially derive from reduced O₂ delivery, altered peripheral O₂ diffusion and a mismatch between O₂ delivery and O₂ consumption, likely related to an altered nitric oxide signaling. Aim of this study was to evaluate the effects of 10 days of BR on microvascular reactivity indexes determined at skeletal muscle level by near infrared spectroscopy and nitric oxide metabolites.

Methods: Measurements were carried out on 10 recreationally active young males (age 23 ± 5 years [mean±SD]) before (PRE) and after (POST) 10 days of horizontal BR. Pulmonary O₂ uptake ($\dot{V}O_2$) and other respiratory, cardiovascular and skeletal muscle variables were determined during an incremental exercise on a cycle ergometer. Microvascular endothelial function was assessed during vascular occlusion test (VOT) by evaluating the slope of re-oxygenation rate (SLOPE 2) and the area under the curve (AUC) over the baseline of 5min reperfusion phase of delta[oxy(Hb+Mb)] signal obtained from vastus lateralis muscle. Plasma nitrite concentration was determined by chemiluminescence.

Results: Peak $\dot{V}O_2$ was lower in POST (41.5 ± 6.5 ml kg⁻¹ min⁻¹) vs. PRE (44.5 ± 7.4 , $P < 0.01$). SLOPE 2 was significantly slower in POST (5.3 ± 0.8 % s⁻¹) compared to PRE (6.4 ± 0.7 , $P < 0.01$). AUC was significantly reduced in POST (11025 ± 2145 % s) compared to PRE (13094 ± 1940 , $P < 0.01$). Plasma nitrite concentration diminished from PRE (85.4 ± 35.0 nM) to POST (65.5 ± 45.6 , $P < 0.01$).

Conclusions: These preliminary data suggest that after 10 days of horizontal BR whole-body impairment of oxidative metabolism during exercise is associated with reduced level of nitrite and an altered microvascular endothelial function. Further analyses of systemic functional variables as well as biochemical data obtained during the bed-rest campaign, and not yet analysed, will help us to define sites of limitation to muscle oxidative metabolism along the O₂ pathway.

(No relevant relationships reported)

Purpose: Traditional two-dimensional (2D) *in vitro* models of human skeletal muscle are limited in their ability to fully mimic *in vivo* muscle, as *in vivo* muscle exists in a complex three-dimensional (3D) structure. We have developed a novel engineered three-dimensional (3D) myobundle *in vitro* model that we believe more closely models skeletal muscle behavior. Here, we determined baseline gene expression differences among three models: the 3D myobundles, 2D cell cultures, and explant biopsies. **Methods:** Previously collected skeletal muscle (vastus lateralis) biopsy samples from adult men and women (n = 6) were used. Each sample was used to generate the following groups: explant (RNA from biopsy), 2D (RNA from differentiated myotubes) and 3D (RNA from 3D myobundles seeded from each primary sample). 200ng of isolated RNA for each sample was used to generate global gene expression profiles (HumanHT-12 v4.0 Gene Expression BeadChip Arrays). Data were processed using Illumina Genome Studio and imported into Partek Genomics Suite for statistical analysis. Differential gene expression was assessed via 2-way ANOVA (group*ID) with the following *post-hoc* comparisons: 2D/biopsy, 3D/biopsy and 3D/2D. Resultant lists were filtered at p<0.01 and fold change >|1.5|. Biological pathway analyses of differentially regulated gene sets were done using Ingenuity Pathway Analysis. **Results:** ANOVA detected 3754 genes different between 2D/biopsy, 3273 genes different between 3D/biopsy and 488 genes different between 3D/2D cultures. Biological pathway analysis identified representation of the following canonical pathways in our gene set: calcium signaling (26 genes; z-score=1.508, -log p-value=13.9), integrin signaling (28 genes; z-score=-2.711, -log p-value=13.5), and actin cytoskeleton signaling (29 genes; -log p-value=12.3). **Conclusion:** The 3D cell myobundle system produced relatively fewer differences from biopsies as compared to 2D cell cultures, but some significant differences from biopsy samples remain. Comparison of 3D to 2D culture systems shows transcriptional changes that align with increases in calcium signaling, while downregulations in the actin cytoskeleton and integrin signaling demonstrate significant structural differences between the two *in vitro* models tested.

2821 Board #282 May 29 10:30 AM - 12:00 PM**Changes In TSH, T4 And Prolactin Levels With Cycling And Running**Costas Chryssanthopoulos¹, Roxane Tenta², Evangelia Tzeravini¹, Elias Zacharogiannis¹, Alexander Kokkinos¹, Maria Maridaki¹, Michael Koutsilieris¹, Anastassios Philippou¹. ¹National and Kapodistrian University of Athens, Athens, Greece. ²Harokopio University, Athens, Greece. Email: chryssan@phed.uoa.gr

(No relevant relationships reported)

Several studies have examined the changes in TSH, T4 and Prolactin levels during cycling and running, however, to the best of the authors' knowledge, none of the existing studies compared directly cycling and running on the same individuals. **PURPOSE:** To compare changes in TSH, T4 and Prolactin levels as a consequence of cycling and running exercise on the same individuals. **METHODS:** Ten active males (25.4 ± 11.0 years old, 175.8 ± 6.9 cm, body fat percentage 15.6 ± 3.6%, mean ± SD), following an overnight fast, cycled (C) or ran (R) for 30 min at about 80% maximal heart rate (HRmax). Venous blood samples were taken before and immediately after exercise. Data were analyzed using two-way ANOVA, whereas post-pre exercise changes were compared by two tailed t-test. **RESULTS:** The two-way ANOVA revealed no differences at any level (time, mode and interaction) before exercise for serum TSH (C: 4.4 ± 7.2 vs. R: 2.7 ± 2.1 μU/ml⁻¹), T4 (C: 1.2 ± 0.2 vs. R: 1.1 ± 0.2 ng/dl⁻¹) and Prolactin (C: 20.0 ± 4.4 vs. R: 20.7 ± 5.5 ng/ml⁻¹) compared to post exercise [TSH: 6.7 ± 11.5 (C) vs. 3.8 ± 3.1 (R) μU/ml⁻¹; T4: 1.3 ± 0.4 (C) vs. 1.2 ± 0.2 (R)

ng/dl⁻¹; Prolactin: 20.9 ± 5.0 (C) vs. 20.3 ± 6.0 (R) ng/ml⁻¹]. No differences were also observed when post-pre exercise values were compared with the exception of a higher percentage change as a result of exercise in C (39 ± 36 %) compared to R (37 ± 20 %) for serum TSH (p=0.01).

CONCLUSIONS: After 30 min cycling or running at about 80% HRmax no significant changes in the levels of serum TSH, T4 and Prolactin were elicited compared to pre-exercise in male active individuals.

2822 Board #283 May 29 10:30 AM - 12:00 PM**The Effect Of A Ketogenic Diet On The Exercise Induced Immune Response**Riencke Terink¹, Renger Witkamp¹, Huub Savelkoul¹, Maria Hopman, FACSM², Marco Mensink¹. ¹Wageningen University & Research, Wageningen, Netherlands. ²Radboud UMC, Nijmegen, Netherlands. ABSTRACT - Purpose: Ketogenic diets are popular amongst athletes, they improve fat oxidation capacity and training with low carbohydrate (CHO) availability can possibly enhance training adaptation. However, performance improvements are not observed and training with low CHO availability may increase the susceptibility to illness and infection. Therefore, the aim of this study was to examine the effect of a (short and longer) ketogenic diet on the exercise induced immune response. **Methods:** in this cross-over study, 14 well trained male athletes (age 32.9±8.2 years, VO2max 57.3±5.8 ml/kg/min) were assigned to two weeks on a low CHO ketogenic (LC) diet (< 10En% CHO) and two weeks on a high CHO (HC) diet (> 50En% CHO) in a random order, with a wash-out period of >2 weeks in between. Test days were planned after 2 days and 2 weeks on both diets. During test days athletes cycled for 90 minutes at 70% VO2max and blood samples were taken at baseline, directly after exercise and 2hr after exercise. Blood samples were analysed for cortisol, immune cell differential count and homing factors. **Results:** Total work load performed during the exercise test was lowest after 2 days on the LC diet (938.6±162.5 kJ) and improved after 2 weeks (1003.2±128.6 kJ, p=0.03), but was still lower compared to the HC diet (~1040 kJ, p>0.05). Cortisol response after exercise was higher after 2 days on the LC diet (822±215 nmol/L) compared to the response after 2 weeks on the LC diet (669±243 nmol/L) and compared to both test days during the HC diet (609±208 and 555±173 nmol/L, both p<0.001). Immune cell differential count, for T-cells, Th cells, Cytotoxic T cells, NK T cells, B cells and monocytes was significantly different between diets (p < 0.05). Differences between diets were more pronounced after 2 days on the diets compared to 2 weeks on the diets. The CCR7+ homing factor on CD4+ cells (which guides cells to lymph nodes) was higher during the LC diet, compared to the HC diet (p < 0.05) **Conclusions:** The short term ketogenic diet caused a higher stress response and more pronounced differences in cell differentiation, compared to the HC diet. In addition, homing of CD4+ cells to the lymph nodes was stronger on the LC diet compared to the HC diet.

2823 Board #284 May 29 10:30 AM - 12:00 PM**Adrenocorticotropin And Interleukin-6 Responses After A Single Bout Of Aerobic Exercise In Young Adults**

Maria Dourida Mitarachi. National and Kapodistrian University of Athens, Athens, Greece.

Email: maria@mitarakis.gr

(No relevant relationships reported)

Exercise is a stress stimulus leading to endocrine and immunological changes in the human body. There are interactions between the Hypothalamo-Pituitary-Adrenal (HPA) axis and the immune system in response to exercise, depending on the characteristics of exercise (type, duration, intensity and frequency). **PURPOSE:** This study examined adrenocorticotropin (ACTH) and interleukin-6 (IL-6) responses to a selected aerobic exercise protocol performed under inhibition or stimulation of the HPA axis in healthy adult volunteers. **METHODS:** twelve healthy volunteers (8 males and 4 females, age: 30.6±4.4 yrs, body mass: 77.3±12.3 kg, height: 1.77±0.07 m), performed a single bout of 30 min aerobic exercise at 70%VO₂max on a treadmill, on three different conditions [control (C), HPA axis inhibition (HPA-I, induced by glucocorticoid administration), HPA axis stimulation (HPA-S, induced by ACTH administration)], following standard diet. Blood samples were collected before (t0), at the end of the exercise bout (t30), and 30 min later (t60) and serum ACTH and IL-6 were measured. Two-way ANOVA was used for statistics and data is presented as mean±SE. **RESULTS:** In C condition, IL-6 increased at the end (p<0.05) and 30 min after exercise (p<0.001) (1.7±0.1; 3.1±0.5; 3.02±0.6 pg/ml; at t0, t30 and t60, respectively). ACTH significantly decreased 30 min after exercise (p<0.05) (23.4±2.3; 21.5±2.4; 16.9±1.6 pg/ml; at t0, t30 and t60, respectively). In HPA-I, IL-6 increased at the end (p<0.05) and 30 min after exercise (p<0.001) (1.6±0.1; 2.4±0.4; 2.9±0.6 pg/ml; at t0, t30 and t60 respectively), while ACTH remained unchanged (p>0.05) (4.0±; 4.1±0.1; 4.3±0.2 pg/ml; at t0, t30 and t60, respectively). Under HPA-S condition, IL-6 increased 30 min after exercise (p<0.01) (1.7±0.2; 2.6±0.3; 3.5±0.7 pg/ml; at t0, t30

and t60 respectively). There were no significant changes in IL-6 between the three conditions, while ACTH was lower in HPA-I compared to C condition at all time points ($p < 0.001$). **CONCLUSION:** The rapid increase of IL-6 in response to aerobic exercise is not affected by the modification of HPA axis, while the specific aerobic exercise regimen influenced circulating ACTH yet not under exogenous inhibition of the HPA axis. Further studies are needed to characterize how those responses are regulated by the characteristics of exercise.

Acute Resistance Exercise Elicits Bdnf But Not Cathepsin B In Well-trained Men

Zac P. Robinson, Trevor K. Johnson, Daniel J. Belcher, Colby A. Sousa, Joseph P. Carzoli, Nishant P. Visavadiya, Andy V. Khamoui, Michael Whitehurst, FACSM, Michael C. Zourdos. *Florida Atlantic University, Boca Raton, FL.*
Email: zrobinson2019@fau.edu
(No relevant relationships reported)

PURPOSE: The aim of this study was to examine if multi-joint RE exercises (back squat, bench press, and deadlift) to volitional failure elicited a circulating response of biomarkers associated with neuroprotection and if differences in biomarker changes existed between exercises. Further, we examined if the pre- to post-exercise changes in BDNF and IL-6 were related. **METHODS:** Thirteen males (age: 24.5 ± 3.8 yrs, body mass: 84.01 ± 15.44 kg, height: 173.43 ± 8.57 cm, training age: 7.1 ± 4.2 yrs) performed 4 sets to failure at 80% of a one-repetition maximum (1RM) on the squat, bench press, and deadlift in successive weeks. The bench press was always performed second and the order of the squat and deadlift was counterbalanced. The measured biomarkers are brain derived neurotrophic factor (BDNF), insulin-like growth factor 1 (IGF-1), cathepsin B (CatB), and interleukin 6 (IL-6). Biomarkers were assessed immediately pre- and post-exercise. **RESULTS:** There was a main time effect ($p < 0.01$) for BDNF. In the deadlift ($p = 0.01$) and bench press ($p = 0.01$) conditions BDNF significantly increased, however, no significant change was observed the squat condition ($p = 0.21$). There was a main time effect ($p < 0.01$) for IL-6 with a significant increase in the squat ($p < 0.01$), but not the bench press ($p = 0.88$) and deadlift conditions ($p = 0.24$). No main time effect was observed for either CatB ($p = 0.62$) or IGF-1 ($p = 0.56$). No significant correlations were observed between the acute change in BDNF and IL-6 ($p > 0.05$), however, this relationship was nearly significant in the deadlift condition ($p = 0.058$). **CONCLUSION:** In summary, acute multi-joint RE elicits a significant increase in circulating BDNF. This investigation is the first to report the lack of a transient change of CatB to an acute RE protocol.

2825 Board #286 May 29 10:30 AM - 12:00 PM

Treadmill Walking Increases Percent Of Circulating Monocytes (CD14+) Expressing CX3CR1 In Older Adults

Victoria E. Warren, Rachel M. Graff, Emily C. LaVoy, Melissa M. Markofski. *University of Houston, Houston, TX.*
(No relevant relationships reported)

CX3CR1 is a chemokine receptor for the chemokine CX3CL1. Expression of CX3CR1 may influence the inflammatory response of the innate immune system. The **PURPOSE:** of this study was to examine the relationship between CX3CR1 expression on circulating monocytes with physical activity level and mode of exercise in healthy, older adults. **METHODS:** Twenty-four healthy older adults (63.0 ± 5.0 years) were recruited for this study. Participants were divided into two groups based on self-reported physical activity level: physically active (PA) and physically inactive (PI). Participants completed a randomized complete crossover trial of 30 minutes moderate-vigorous intensity cardiorespiratory endurance (CRE) or resistance exercise (RE) on two separate visits. Blood samples were collected from each person at rest (PRE), immediately after exercise (POST), and 1-hr recovery after exercise (RECOV). Monocyte cell surface markers were measured by flow cytometry. **RESULTS:** PA participants ($N = 12$, est. $\dot{V}O_{2\max} = 45.3 \pm 16.8$ mL \cdot kg $^{-1}$ \cdot min $^{-1}$) had a higher estimated $\dot{V}O_{2\max}$ than the physically inactive participants ($N = 12$, est. $\dot{V}O_{2\max} = 35.0 \pm 11.1$ mL \cdot kg $^{-1}$ \cdot min $^{-1}$). Percent of circulating monocytes expressing CX3CR1 was higher ($p < 0.05$) in CRE RECOV ($92.3\% \pm 2.5$) than CRE POST ($90.1\% \pm 2.98$). No other differences ($p \geq 0.05$) were observed within the PA group between PRE, POST, and RECOV timepoints for the CRE or RE modes of exercise. No differences ($p \geq 0.05$) were observed within the PI group for time or mode of exercise. No differences ($p \geq 0.05$) were observed between the CRE and RT modes of exercise within the PA group or the PI group at each PRE, POST, and RECOV timepoints. **CONCLUSION:** Differences in monocyte expression of CX3CR1 were observed between the POST and RECOV stage following a 30-minute CRE (treadmill) exercise intervention within the PA group. Time differences were observed between PA and PI groups. No other differences in CX3CR1 were observed within PA and PI groups following a 30-minute moderate-vigorous exercise intervention. Further research is needed to determine potential differences if CX3CR1 physical activity status and mode of exercise influence the inflammatory response of an acute exercise bout.

Resistance Training On Specific MicroRNAs In Physiological Adaptations In Older Adults

HUNG-WEN LIU. *National Taiwan Normal University, Taipei, Taiwan.*
Email: hwliu@ntnu.edu.tw
(No relevant relationships reported)

PURPOSE: MicroRNA (miRNA) as the novel regulator in resistance training induced functional and physiological adaptations remains poorly understood. The goal of the present study was to analyze the response of a panel of circulating miRNAs to resistance training-mediated adaptations.

METHODS: Ten healthy older adults (age: 67.6 ± 2.2 years, BMI: 22.8 ± 2.6 kg/m 2 , 7 female, 3 male) without previous resistance training experience were recruited. Blood samples were collected at baseline (PRE) and after 12 week of resistance training (POST). Next-generation sequencing (NGS) was used to determine circulating microRNA responses to chronic resistance training.

RESULTS: Physical function, including grip strength, chair stand test, and walking capacity, was improved in older adults after 12-week training. Serum levels of leptin (18.1 ± 20.0 vs. 14.9 ± 17.6 ng/ml, $P = 0.029$) and TNF α (4.4 ± 0.6 vs. 4.0 ± 0.6 pg/ml, $P < 0.001$) were significantly decreased after 12-week training. After 12 week of resistance training, 11 adipogenesis, 3 anti-adipogenesis, 5 myogenesis, and 5 inflammation associated miRNAs were changed significantly in older adults (Fold change > 2 , $P < 0.05$). Log $_{2}$ fold change of miRNA-125-1-3p was inversely correlated with delta walking time ($R = -0.685$, $P = 0.029$) and change in IGF-1 ($R = -0.644$, $P = 0.044$). **CONCLUSIONS:** Resistance training alters specific circulating miRNAs to account for functional and physiological adaptations in older adults.

Genetic Predictions Of Bone Mineral Density In Ultramarathon Runners: For Men, But Not For Women

Emily K. Miller, MD¹, Michael Fredericson, MD, FACSM¹, Megan Roche, MD¹, Kira Skaggs, BS¹, Tracy Beth Hoeg, MD², Kristin Sainani, PhD¹, Emily Kraus, MD¹. ¹Stanford University, Redwood City, CA. ²University of California - Davis, Sacramento, CA.
Email: emily.kristine.miller@gmail.com
(No relevant relationships reported)

BACKGROUND: Various genetic markers have been identified as influencing bone mineral density (BMD). In a prior study in the UK Biobank, 22,866 SNPs were selected using LASSO based on ability to predict calcaneal bone mineral density. Kim in PLoS ONE 2018 tested this genetic risk score against other models and found it to have the best correlation with BMD.

PURPOSE: Given the prevalence of low BMD and low energy availability in female and male endurance runners, this study investigated the correlation between this genetic risk score and BMD of runners at the Western States endurance race.

METHODS: 51 runners at a 100-mile race underwent a genetic evaluation using an Affymetrix PMRA array including approximately 800,000 SNPs, which includes all those required for the Kim BMD genetic risk score. These runners also underwent dual-energy x-ray absorptiometry. We calculated Pearson's correlation coefficients between the genetic risk score and spine, hip, femoral, and forearm BMD.

RESULTS: 17 female and 34 male participants had a mean age, respectively, of 41.8 and 46.8 years (range 26.4-76.2). BMI ranged from 17.2-25.2 kg/m 2 (female) and 19.3-39.4 kg/m 2 (male). For the male runners, the genetic risk score significantly correlated with z-scores of the lumbar spine, total hip, femoral neck, forearm, and total body ($r = 0.52-0.58$, $p < 0.005$). For female athletes, all correlations were 0 or negative and non-significant ($r = 0.0$ to -0.30 , $p = 0.24-0.99$). See Table 1.

CONCLUSIONS: The BMD genetic risk score was significantly correlated with BMD in the male, but not female ultramarathon runners in this study. The sample size for women ($n = 17$) is too small to draw robust conclusions, but we speculate that for female athletes, environmental and hormonal factors, such as low energy availability or menstrual irregularities, may decrease the influence of genetic factors.

Correlation Between Genetic Risk Score and Bone Mineral Density					
	Spine Z-Score R, p-value	Total Hip Z-Score R, p-value	Femoral Neck Z-Score R, p-value	Forearm Z-Score R, p-value	Total Body Z-Score R, p-value
Women: Genetic Risk Score	0, 0.99	-0.16, 0.53	-0.06, 0.83	-0.3, 0.24	-0.11, 0.68
Men: Genetic Risk Score	0.52, 0.0016	0.64, <.0001	0.53, 0.0013	0.58, 0.0003	0.58, 0.0003

Football Years Played Has A Dose-response Relationship With Odds Of Having Chronic Traumatic Encephalopathy And Severity Of Disease

Daniel Hamed Daneshvar¹, Jesse Mez², Ann McKee³. ¹Stanford, Redwood City, CA. ²Boston University, Boston, MA.
(No relevant relationships reported)

PURPOSE:

Chronic traumatic encephalopathy (CTE) is a neurodegenerative disease associated with exposure to contact and collision sports, including American football. We hypothesized that, as duration of American football played increased, CTE neuropathological risk and severity would correspondingly increase. To account for selection bias, we adjusted for known predictors of selection into brain banks using inverse probability weighting (IPW); because of unique criteria, we also conducted simulation to further evaluate the effect of selection bias. **METHODS:** In a convenience sample of 266 deceased American football players from the VA-BU-CLF and Framingham Heart Study (FHS) Brain Banks, we estimated the association of years of football played with CTE pathological status and severity. To be eligible the VA-BU-CLF Brain Bank, donors needed a history of CCS, military service, or domestic violence, regardless of whether symptoms manifested during life. All brains from either brain bank were processed and analyzed using identical methods. Neuropathologists were blinded to the participant's CCS exposure and clinical history.

RESULTS:

In models adjusted for age at death, there was a dose-response relationship between longer duration played with CTE status and severity; each additional year of play corresponded to 30% higher odds of having CTE at death (95%CI, 1.19-1.41; $P=3.8 \times 10^{-9}$) and 14% higher odds of having severe CTE at death (95%CI, 1.07-1.22; $P=3.1 \times 10^{-4}$). Participants with CTE were 1/10th as likely to have played <4.5 years (negative likelihood ratio [LR]=0.102, 95%CI, 0.100-0.105) and were 10X as likely to have played >14.5 years (+LR=10.2, 95%CI, 9.8-10.7). Simulation demonstrated that years played remained adversely associated with CTE status across all values of selection regression scenarios.

CONCLUSIONS:

Duration played was significantly associated with odds of CTE at death, with odds increasing 30% every year, doubling every 2.6 years and increasing by >10-fold every nine years. Among those with CTE, duration played also was also significantly associated with having severe CTE pathology and greater NFT burden. Duration played was a good classifier of CTE status based on ROC curve analysis.

Vestibular/ocular Motor Screening: Evaluation Of A Novel Prototype For Injury Assessment

Philip Pavilionis¹, Sushma Alphonso¹, Cameron Kissick¹, Madison Taylor¹, Ryan Moran², Nora Constantino¹, Nicholas Murray¹. ¹University of Nevada, Reno, Reno, NV. ²University of Alabama, Tuscaloosa, AL.
Email: ppavilionis@unr.edu
(No relevant relationships reported)

The Vestibular/Ocular Motor Screening (VOMS) is a common tool to evaluate sport-related concussion (SRC). Unfortunately, it is possible that conventional assessments can be subjective and elicit inconsistent results between raters with respect to how each rater perceives the position of their hands. If this occurs, it may alter the distance the eye must travel during pursuits and saccades, to complete sections of the exam and could influence symptom reporting. **PURPOSE:** The purpose of this study was to examine the differences in the VOMS using the traditional method (TRAD) versus using a clinical prototype (PRO) within 72 hours of a sport-related concussion. **METHODS:** 11 SRC (Female = 4, Male = 7, average age = 19 years) completed the VOMS assessment using the TRAD method and 11 SRC (Female = 4, Male = 7, average age = 22 years) completed the VOMS using the PRO method. For the TRAD method, arm position was not controlled and each trained rater was asked to administer the exam normally. For the PRO, it consisted of an adjustable, vertical pole affixed to a tripod stand with a leg of the stand that extended to 36 inches. At the upper end of the vertical pole, a second pole was affixed via a pivot clamp. The length of this pole was 36 inches with 2 white 14 point markers affixed to either end. One end of this part of the prototype contained a secondary pole that had a slide rule device that can be extended out to the end of the nose when aimed at the face to allow for the measurement for NPC. All SRCs were assessed within 72 hours post-injury. Mann-Whitney U tests assessed the differences between both methods of assessment for total symptom severity changes and NPC distance.

RESULTS: The results indicate that using the TRAD method (average=12±8 symptoms severity) elicited a significantly greater amount of change score symptom severity when compared to the PRO (average=5±4 symptoms severity; $p=.016$, Cohen's $d=1.1$). However, no significant difference was noted on NPC between TRAD (average=8.5±7.1cm) and PRO (average=13.1±9.8cm; $p=.32$, Cohen's $d=0.6$). **CONCLUSION:** The TRAD elicited a greater change in symptom severity but no changes were observed in NPC. A standardized measurement tool may reduce the distance that the eyes travel during the assessment which could elicit less overall symptoms on the VOMS and avoid human error due to subjective evaluation.

Predicting Protracted Concussion Recovery To Inform Proactive Care: A Genetic Fuzzy Machine Learning Approach

Adam W. Kiefer¹, Anoop Sathyan², Christy Reed³, Gregory Walker⁴, Jackson Elpers², Paul Gubanich³, Kelly Cohen², Kelsey Logan³. ¹University of North Carolina at Chapel Hill, Chapel Hill, NC. ²University of Cincinnati, Cincinnati, OH. ³Cincinnati Children's Hospital Medical Center, Cincinnati, OH. ⁴Children's Hospital Colorado, Aurora, CO.
Email: awkiefer@email.unc.edu
(No relevant relationships reported)

Poor prognostic accuracy of sport-related concussion (SRC) recovery times has limited proactive clinical care. Currently, clinicians consolidate a battery of assessments and combine their own practical knowledge to develop prognosis and treatment plans. Machine learning may provide a useful method to augment clinicians' prognostic decision making: a critical first step to enhance proactive care.

Purpose: Determine utility of a novel genetic fuzzy system (GFS) machine learning approach, FuzzyBolt, to predict protracted recovery after SRC.

Method: Data from 76 pediatric patients (age 14.44 ± 2.54 years; 28 F) were obtained from 186 combined clinic visits following initial SRC. Recovery time was indexed from the physician-recorded full clearance to return to play date in the medical record and then classified as less than or equal to 28 days (N=88) vs. greater than 28 days (N=98)—the consensus pediatric threshold for persistent symptoms. A GFS model classified protracted recovery on patients that were less than 28 days in recovery. GFS uses fuzzification, rule-inference and defuzzification to make decisions, and FuzzyBolt provides an efficient method of optimizing model parameters via genetic algorithms. The model used 36 inputs, including ordinal and binary variables related to patient demographics, standardized Post-Concussion Symptom Inventory responses, and self-reported responses from a clinic-based Head Injury Questionnaire.

Results: Data were split, via stratified sampling, into a training set (80%; 61 athletes with 151 visits) and a hold-out validation set (20%; 15 athletes with 35 visits). Each patient visit was considered a unique case, with visits from the same patient never part of both the training and validation sets to reduce the risk of over-fitting and inflation of non-generalizable prediction accuracy. The FuzzyBolt model correctly predicted 12 of 16 protracted (and 16 of 19 typical) recovery cases, for an overall classification accuracy of 80%.

Conclusion: This is the highest prediction accuracy, to date, for any published prognostic model of concussion recovery. It is a first step toward promoting early allocation of resources for patients at high-risk for protracted recovery, and demonstrates a novel technique to empower a data-driven solution to improve outcomes in these athletes.

Predictors Of Sport-related Concussion Non-disclosure In Collegiate Athletes

Morgan Anderson¹, Kyle M. Petit¹, Abigail C. Bretzin², Jessica Wallace³, Tracey Covassin¹, Erica Beidler⁴. ¹Michigan State University, East Lansing, MI. ²University of Pennsylvania, Philadelphia, PA. ³University of Alabama, Tuscaloosa, AL. ⁴Duquesne University, Pittsburgh, PA.
Email: ande1997@msu.edu
(No relevant relationships reported)

Sport-related concussion (SRC) non-disclosure continues to be a barrier to injury identification, despite recent National Collegiate Athletics Association educational initiatives to increase favorable reporting behaviors. Therefore, understanding factors associated with SRC non-disclosure in collegiate athletes is warranted. **PURPOSE:** To examine predictors of SRC non-disclosure in collegiate athletes. **METHODS:** A multisite cross-sectional design was used. Collegiate athletes (n = 741; males = 448, females = 293; mean age = 19.89 ± 1.32 years) completed a 15-minute survey that included personal and sport demographics, diagnosed and non-disclosed SRC history, and pressure from external sources (i.e., coaches, teammates, family/parents, fans) to continue to play following a head impact. Age, sex (male/female), sport type (contact/non-contact), SRC history (yes/no), and degree of pressure from external sources (1-strongly disagree to 7-strongly agree) were potential predictor variables

of SRC non-disclosure. Univariate logistic regression analyses determined the odds of SRC non-disclosure (yes/no) for each predictor. Significant univariate predictor variables were used in the multivariate logistic regression analysis. Significance was set *a priori* at $p \leq .05$. **RESULTS:** A total of 116 (15.65%) collegiate athletes reported not disclosing a potential SRC. Following univariate logistic regression analysis, sex ($p = .004$), sport type ($p = .002$), SRC history ($p < .001$), pressure from teammates ($p < .001$), pressure from coaches ($p < .001$), pressure from parents/family ($p < .001$), and pressure from fans ($p < .001$) were entered into a multivariate logistic regression. Previous history of SRC (OR, 2.66, [95% CI 1.74-4.08]; $p < .001$), being a male (OR, 1.69 [95% CI, 1.04-2.75]; $p = .033$), and experiencing pressure to play following a head impact from a coach (OR, 1.36 [95% CI 1.16-1.59]; $p < .001$) were significant predictors of SRC non-disclosure. **CONCLUSIONS:** SRC non-disclosure behaviors are influenced by intrinsic and extrinsic factors and may be magnified in athletes with a history of SRC, males, and athletes that experience pressure from coaches. To reinforce favorable reporting behaviors, future educational initiatives should consider these predictive factors.

2832 Board #293 May 29 9:30 AM - 11:00 AM
The Relationships Between King-devick And SCAT5 Scores In High-school Athletes

James P. Toldi¹, Robert L. Herron², Brandon D. Spradley², Dani Ellis³, Chelsea L. Best³, Ashley D. Marass¹, Anthony M. Martino¹. ¹University of South Alabama College of Medicine, MOBILE, AL, ²United States Sports Academy, Daphne, AL. ³Encore Rehab, MOBILE, AL.
 Email: jtoldi@health.southalabama.edu
 (No relevant relationships reported)

Preseason testing is important when developing concussion-related safety programs in high-school athletes. However, the relationships between many commonly-used and valid-baseline assessments are unknown

PURPOSE: To determine the relationships between King-Devick (KD) and the Sport Concussion Assessment Tool - 5th Edition (SCAT5), commonly used as part of a pre-season concussion-safety program for high-school athletes. **METHODS:** SCAT5 and KD baseline scores from high-school athletes ($n = 404$, 28 = female, aged 16 ± 1 years) were recorded and later analyzed. KD testing required participants to complete two, error-free trials, which were reported to the nearest 0.0 s and a single SCAT5 assessment completed one-on-one with a physician or athletic trainer. The SCAT5 test is composed of several relevant neurocognitive components (concentration, current number of symptoms, symptom severity, orientation, memory, neurological screening, balance, and recall). Due to the dichotomous nature of the neurological screening component, those data were excluded from this analysis ($n = 9$ scored in the abnormal category). Pearson-product moment correlations were calculated between the best-baseline KD score and SCAT5's component tests, including a composite score. The composite score was calculated as a sum of z-scores from each individual test making up the SCAT5. **RESULTS:** The mean \pm standard deviation of the KD test were 52.5 ± 13.3 s. Pearson-product moment correlations revealed a weak-negative relationship with the SCAT5 component - Concentration ($r = -0.12$, $p = 0.02$). However, no other meaningful relationships were detected [number of symptoms ($r = -0.04$, $p = 0.48$), symptom severity ($r = -0.06$, $p = 0.22$), orientation ($r = -0.07$, $p = 0.14$), memory ($r = -0.02$, $p = 0.63$), balance ($r = -0.04$, $p = 0.39$), recall ($r = 0.01$, $p = 0.88$), and composite z-score ($r = -0.05$, $p = 0.30$)] **CONCLUSIONS:** These data show that KD and SCAT5 scores are generally unrelated in this sample of high-school athletes. Clinically, the data support the true utility of neurocognitive testing resides in one's ability to use the same test to directly compare pre- vs. post-test scores in diagnosing and monitoring recovery in athletes suspected of having a concussion. King-Devick provided access to testing services - free of charge.

2833 Board #294 May 29 9:30 AM - 11:00 AM
A New Objective Visual Test For Concussion

Adrian John Cohen. *Headsafe, Bronte, Australia.*
 Email: ado@headsafecom
 Reported Relationships: **A.J. Cohen:** Ownership/interest/stock; Founder, CEO and shareholder.

PURPOSE: A wide variety of assessment tools are currently available to help clinicians assess Sports Related Concussion (SRC). Currently, the most widely available tools are neither objective nor portable and are therefore not ideal for assessment at the site and time of a suspected injury. **METHODS:** A portable system was developed to deliver a measurement of the steady-state visual-evoked potential (SSVEP). This system involved a smartphone housed in a Google Cardboard frame, which delivered a 15Hz flicker visual stimulus while an electroencephalography (EEG) headset recorded EEG signals. 65 rugby union players were tested during their regular season and were stratified into healthy, concussed and recovered groups based on clinical examination. Their SSVEP response was quantified into a signal-to-noise ratio (SNR). The SNRs of players in each study group were summarized. Additionally, the SNRs of individual players who had baseline, post-injury and post-recovery readings

were analyzed. **RESULTS:** 65 participants completed a baseline evaluation to measure their SSVEP. Twelve of these participants sustained a medically diagnosed concussion and completed SSVEP re-testing within 72 hours. Eight concussed players received follow-up SSVEP testing after recovery. Concussed participants had a lower SNR (2.20 [2.04-2.38]) when compared to their baseline (4.54 [3.79-5.10]). When clinically recovered, participant SNR was not significantly different to their baseline (4.82 [4.13-5.18]). The baseline SNRs of the players who experienced a concussion during the season were not different to those of players who did not experience a concussion (4.80 [4.07-5.68]). **CONCLUSIONS:** This is the first study to identify differences in SSVEP responses in male amateur rugby union players with and without concussion. It is also the first SSVEP demonstration for concussion evaluation at point-of-care. SSVEPs are significantly attenuated in the presence of concussion in these male athletes. Individuals returned to their baseline SSVEP following clinical recovery from the concussive injury. The use of SSVEPs has the potential to be a supplemental aid for the assessment and management of concussion.

2834 Board #295 May 29 9:30 AM - 11:00 AM
Validity And Reliability Of The Balance Error Scoring System BESS In Deaf Neurosensory Athletes

Diana A. Camargo Rojas¹, Daniela Duran¹, Brayan Valencia¹, Viviana Villamizar¹, Nicolas Figueroa², Victor Vargas².
¹Universidad Nacional de Colombia, Bogotá, Colombia.
²Movylab SAS, Bogotá, Colombia.
 Email: dacamargor@unal.edu.co
 (No relevant relationships reported)

Purpose: People with hearing impairment have motor and vestibular deficit, which affects the function of static balance. It has been demonstrated the importance of the performance of static balance in athletes in relation to the sports performance, the presence of injuries and as part of the training for the prevention of them. The objective of this study was to determine the reliability and validity of the BESS scale in athletes with hearing impairment of neurosensory origin practicing basketball and soccer in the Bogotá league. **Materials and Method:** Validation study of a diagnostic test instrument, in which translation of the protocol into Colombian Spanish and reverse translation was performed by certified translators. The determination of content validity was carried out by means of expert consensus. The inter, intra evaluator and the test-retest reliability, by Friedman test. By means of the comparison with stabilometry the criterion validity was done. By means of the comparison with stabilometry the criteria validity was done, through the Pearson correlation coefficient. The data base was managed in Excel and the data processing was done with the software R version 3.5. Facto mine R for the process analysis of main components. **Results:** It was achieved to adapt the BESS to Colombian Spanish for soccer and basketball players, as well as its adaptation into Colombian sign language. According to the consensus of experts, the agreement percentage is 95.3 based on the criterion of coherence, relevance and sufficiency evaluated in the protocol. The intra-rater reliability showed variations in the qualification due to the subjectivity of the test administered. On the other hand, the inter-rater reliability showed p values >0.05 for the firm stance feet together, unsteady feet together and unstable one foot. The reliability test-retest reflects stability in the qualification in short periods of time with p values >0.05 for all positions and total rating of BESS. The criterion of validity showed a strong Pearson correlation coefficient with p value of 0.57 for the BESS total compared with stabilometry. **Conclusions:** The BESS is a valid static balance assessment method to be applied in the sports field for deaf professional soccer and basketball athletes. Moreover, this test is not sensitive to change in short periods.

2835 Board #296 May 29 9:30 AM - 11:00 AM
The Diagnostic And Prognostic Utility Of Dual-task Tandem Gait For Pediatric Concussion

Katie A. Van Deventer, Corrine N. Seehusen, Gregory A. Walker, Julie C. Wilson, David R. Howell. *Children's Hospital Colorado, Aurora, CO.*
 (No relevant relationships reported)

Background: Tandem gait performance is part of the Sports Concussion Assessment Tool (SCAT), but its diagnostic and prognostic value has not been fully assessed in pediatric concussion. **Purpose:** To determine the diagnostic and prognostic value of single-task and dual-task tandem gait by comparing performance of subjects with concussion relative to controls, as well as subjects who developed Persistent Post Concussion Symptoms (PPCS) and those who did not (No PPCS). **Methods:** Subjects seen within 21 days of concussion and uninjured controls completed a single/dual-task tandem gait test battery and modified Balance Error Scoring System (mBESS) test. During the tandem gait test, subjects walked in a heel-toe manner along a 3m strip of fabric down and back as fast as possible. During dual-task trials, they completed a concurrent cognitive task. Outcomes included tandem gait time to completion, cognitive accuracy, and mBESS errors. Subjects with concussion were followed until symptom resolution and sub-grouped into those who developed PPCS (>28 d time to symptom resolution) vs. No PPCS. **Results:** We evaluated 29 subjects with concussion

who developed PPCS (mean age=15±2 years; 62% female; tested 12±6 days post-injury), 58 subjects with concussion who did not develop PPCS (mean age=14±3 years; 36% female; tested 8±5 days post-injury), and 58 controls (mean age= 16±1 years; 42% female). Subjects with concussion performed significantly worse than healthy controls on single-task tandem gait (24.4±12.6 vs. 14.9±3.6 s; $p<0.001$; area under curve [AUC]=0.85), dual-task tandem gait (33.3±14.9 vs. 20.6±7.1 s; $p<0.001$; AUC=0.84), dual-task cognitive accuracy (82.1±12.5 vs. 89.1±18.9 %; $p=0.01$; AUC=0.61), and mBESS (6.5±4.9 vs. 3.8±3.4 errors; $p=0.001$; AUC=0.68). The PPCS sub-group performed dual-task tandem gait significantly slower than the No PPCS group (38.8±17.7 vs. 30.6±12.7 s; $p=0.016$; odds ratio=1.04), but PPCS and No PPCS groups were not significantly different on other measures. **Conclusions:** Pediatric patients with concussion have impaired performance on balance and gait measures compared to healthy controls. Dual-task tandem gait test specifically showed diagnostic value for pediatric concussion and prognostic value in differentiating subjects who developed PPCS compared to those who did not.

Clinical Predictors Of Prolonged Recovery From Sport-related Concussion: Importance Of Early Clinical Care

Shawn R. Eagle, Aaron Sinnott, Anish Puligilla, Vanessa Fazio-Sumrok, Nathan Kegel, Michael W. Collins, Anthony P. Kontos.
University of Pittsburgh, Pittsburgh, PA.
 Email: seagle@pitt.edu
 (No relevant relationships reported)

Initiation of clinical care may play a critical role in promoting recovery following sport-related concussion (SRC). There has been no research on the role of time to first clinic visit on recovery following SRC in pediatric athletes. Rapid recovery may be especially important in pediatric populations, as prolonged recovery may lead to developmental challenges and/or impact schoolwork and learning capacity. **PURPOSE:** To investigate the association of time to first clinic visit (≤ 7 days compared to 8-20 days from injury) in relation to other pre- (e.g., sex; concussion, migraine history) and post-injury (e.g., symptoms, impairment) predictors to prolonged recovery (>30 days) in pediatric athletes with SRC.

METHODS: This study was a retrospective review of medical records from a concussion-specialty clinic representing 164 pediatric athletes (aged 12-17) with diagnosed SRC between April 2016-January 2019. Participants were separated into EARLY (≤ 7 days) and LATE (8-20 days) time to first clinic visit cohorts. Participants completed the Post-concussion Symptom Scale (PCSS), Immediate Post-concussion Assessment and Cognitive Testing (ImPACT), Vestibular/Ocular Motor Screening (VOMS), and demographics/medical history. Adjusted odds ratios (OR) were derived from a backwards stepwise logistic regression (LR) with normal (≤ 30 days) or prolonged (>30 days) recovery as the outcome. Time to first clinic visit, pre-injury factors, and post-injury clinical assessments were included as predictors.

RESULTS: There were no differences in age or cognitive performance between EARLY and LATE. EARLY had a higher PCSS score (29.4±19.6) than LATE (22.2±18.3; $p=0.018$). LATE had a higher proportion of females (55%) than EARLY (28%; $p<0.001$). The LR ($R^2=0.14$, $p<0.001$) identified days to first clinic visit ($OR=2.9$; $p=0.007$), as the strongest predictor of recovery >30 days. Vestibular dysfunction ($OR=1.1$; $p=0.040$) and PCSS score ($OR=1.04$; $p=0.004$) were also predictors of recovery >30 days. **CONCLUSIONS:** Among all pre- and post-injury predictors, days to first clinic visit was the most robust predictor of prolonged recovery. Vestibular dysfunction and PCSS score also predicted prolonged recovery. The findings highlight the importance of early intervention and care following SRC in pediatric populations.

Association Between Post-concussion Intra-individual Variability In Sleep And Step Counts: An Exploratory Study

Nicole L. Hoffman¹, Catherine O. Feltner², Patrick J. O'Connor³, Michael D. Schmidt³, Robert C. Lynall³, Julianne D. Schmidt³.
¹Illinois State University, Normal, IL. ²LSU Health Shreveport – School of Medicine, Shreveport, LA. ³University of Georgia, Athens, GA.
 Email: nlhoff1@ilstu.edu
 (No relevant relationships reported)

Evidence supports transient increases in intraindividual variability (IIV) in sleep post-concussion, a time when physical activity may be reduced. Acute and chronic physical activity impacts sleep, including reducing wake after sleep onset (WASO) and increasing total sleep time (TST).

PURPOSE: To determine the association between IIV in sleep and physical activity in concussed individuals and matched controls one and two weeks post-injury.

METHODS: Twenty college students were physician-diagnosed with a concussion. Eleven concussed individuals with symptom duration ≥ 14 days (23.6±8.6 days) were included in this analysis to examine sleep across two full weeks post-injury.

Non-concussed controls ($n=11$) were well-matched on age, sex, physical activity, and subjective sleep quality. A wrist-worn ActiGraph monitor was provided during initial evaluation (within 72 hours post-injury for concussed) and worn continuously until symptom resolution (duration matched for non-concussed controls). Intraindividual coefficient of variations were calculated for the first week and second week post-injury for each sleep outcome: sleep onset latency (SOL), WASO, TST, sleep efficiency, and number of awakenings. Daily total step counts were also obtained from the ActiGraph monitor and averaged across each week (STEPS). Pearson correlations were conducted per group and separately during weeks 1 and 2 post-injury ($\alpha = 0.05$) to examine associations between STEPS and IVV in sleep.

RESULTS: Across week 1 post-injury, concussed individuals with a greater step count (week 1 average: 12,214±2000 steps) experienced greater IVV in WASO ($r = 0.67$, $p = 0.023$) and less IVV in TST ($r = -0.68$, $p = 0.022$). No significant associations existed in other sleep outcomes or in the matched control group across week 1. No associations were evident in either concussed or control groups for week 2.

CONCLUSIONS: Concussed individuals who were more active across week 1 post-injury experienced greater night-to-night sleep fragmentation variation but experienced a more consistent nighttime sleep duration schedule. The findings from this exploratory study warrant examining associations between sleep IVV and physical activity in a larger study of concussed and non-concussed individuals.

Is Heading The Ball Dangerous In Youth Girls Who Play Soccer?

Luis R. Lopez-Roman¹, Yarimar I. Diaz-Rodriguez².
¹Universidad del Sagrado Corazon, San Juan, PR. ²Universidad Maimonides, Buenos Aires, Argentina.
 (No relevant relationships reported)

In United States at least 1.6 million of girls under 12 years old play soccer. The participation of girls in the sport of soccer continues to increase in the United States, currently soccer is in the third position of preference among high school women.

At this age at least one in two girls will receive a subconcussive impact on the head area in any game situation. Subconcussive impacts are impacts to the head or body that cannot be diagnosed as a concussion on clinical grounds or with neuroimaging studies (MRI, CT-Scan or PET Scan). A subconcussive impact may alter different cognitive functions that could be related to learning without this being able to be identified. Accelerometers are reliable instruments for assessing the magnitude and direction of head impact live in full play. The ImPACT Pediatric® is a neurocognitive test that provide pre and post information of changes before and after receiving an impact on a game. **PURPOSE:** To identify the area of the head where girls receive the most impacts during a game and evaluate if there is any association in cognitive changes. **METHODS:** A group of 15 youth female's soccer athletes between 9 to 11 years old (9.9 ± 0.6 years) wear a head accelerometer in a specialize headband. Each participant was encouraged to perform normally in the game. Descriptive statistics was used to assess subconcussive impacts. T-test was used for the neurocognitive pre and post-test to assess differences in rapid processing. **RESULTS:** Range of acceleration was from 17 g to 36g (Ave= 21.8 ± 6.6 g). T-Test showed differences in sequential memory for female ($p = 0.02$) A total of 13 impacts were received in three games. **CONCLUSION:** The results of this research suggest that one in two girls will receive some impact on the head during the game. There is also a high probability (62%) of receiving the impact on the frontal area of the head associated with cognitive functions as attention, memory and executive functions.

Effects Of Maximal Exercise On Vestibular/Ocular Motor Screening And Postural Control
 Ryan N. Moran¹, Nicholas G. Murray², Michael R. Esco¹, Ward Dobbs¹. ¹The University of Alabama, Tuscaloosa, AL. ²University of Nevada, Reno, NV.
 Email: rnmoran@ua.edu
 (No relevant relationships reported)

Multifaceted, vestibular-related assessment tools have received increased consideration in the sideline assessment of concussion. Specifically, vestibular/ocular motor screening (VOMS) and postural control are two, vestibular-related tools that are receiving attention. Since athletes are often in a state of exertion during the immediate evaluation of a concussion, it is imperative to understand the effects of exercise on these screening tools.

PURPOSE: To examine the effects of maximal exercise testing on VOMS and postural control.

METHODS: Seventeen, healthy college-aged individuals (20.7±2.3 years) completed a baseline VOMS and modified Clinical Test for Sensory Interaction and Balance

(m-CTSIB) for postural control, followed by a graded maximal exercise treadmill test. VOMS measures consisted of symptom provocation scores per item and distance (cm) for convergence. Measures of the m-CTSIB consisted of sway index scores per task. **RESULTS:** Pre- to post-exercise symptom provocation score differences did not exist on any VOMS item, specifically, smooth pursuits (0.12 vs. 0.29, $p=0.18$), saccades (horizontal: 0.18 vs. 0.29, $p=0.70$; vertical: 0.24 vs. 0.41, $p=0.70$), convergence (2.78cm vs. 3.99 cm, $p=0.27$), vestibular ocular reflex (VOR) (horizontal: 0.59 vs. 0.94, $p=0.31$; vertical: 0.41 vs. 0.65, $p=0.27$), and visual motion sensitivity (VMS) (0.47 vs. 0.94, $p=0.13$). However, m-CTSIB sway index score differences from pre- to post-exercise only existed on the eyes open-firm surface (0.43 vs. 0.57, $p<0.001$) task. No differences existed on sway index scores during eyes closed-firm surface (0.65 vs. 0.81 ($p=0.06$), eyes open-foam surface (0.68 vs. 0.74, $p=0.15$) and eyes closed-foam surface (1.80 vs. 1.96, $p=0.11$) tasks. **CONCLUSION:** Eyes open-firm surface (using somatosensory, visual, and vestibular sensory input) task of the m-CTSIB was negatively influenced by exercise. VOMS items remained consistent from pre- to post-exercise, along with eyes closed-firm surface and both foam surface conditions, further validating their utility on sideline assessment.

Heart rate variability (HRV) is viewed as a measure of autonomic nervous system (ANS) function. Various approaches are available for recording heart rate, however, few studies have compared Holter type recordings vs heart rate monitors (HRM) during orthostatic challenges. **PURPOSE:** Compare HRV measures from an electrocardiogram (ECG) Holter and HRM for further investigation on ANS response usefulness for post-concussion rehabilitation follow-up. **METHODS:** Asymptomatic subjects ($n=12$; 6 females, 6 males), age 18 to 35 yrs, non-smoking, no history of cardiac illness and physically active (3 times per week, 60 mins, moderate intensity exercise) participated in the study. ECG signals were recorded in a 12 lead configuration with a Holter (Medilog FD12plus, Schiller, Sw and proprietary HRV analysis software) and simultaneously with an HRM (H10, V800, Polar, Fi and Kubios HRV analysis software). A spacious room with controlled environment was used to assess the orthostatic challenge. A motorised tilt table was set at 180 degrees for supine and 85 degrees for standing position. Participants were instructed to remain for 7 minutes in each of the following positions: supine and standing. Analysis was performed for obtaining temporal and frequency domains measurement in both positions. ANOVA analysis was used to compare measurements obtained from both systems. Pearson correlations were used for comparing same variables measured with both systems. Significance was set at $p<0.05$. Results are presented as means \pm SD were appropriate. **RESULTS:** No significant differences were observed between measurements taken with both systems under equal conditions (supine and standing). Significant differences, however, were observed between conditions (supine and standing), except for SDNN that did not show any significant differences between systems and conditions. Same variables under similar conditions were significantly correlated ($r=0.75-0.95$, $p<0.05-0.001$). **CONCLUSION:** Both recording and analysis systems (Holter vs HRM) yielded comparable results. Thus, both systems appear valid and interchangeable for HRV analysis whilst orthostatic challenge.

Utility Of A Custom Accommodation Convergence Ruler For Measuring Near Point Convergence On The Voms

Byanna Brown¹, Phillip Pavilonis¹, Sushma Alphonsa¹, Cameron Kissick¹, Madison R. Taylor¹, Brian Szekely¹, Nora Constantino¹, Ryan Moran², Nicholas G. Murray¹. ¹University of Nevada, Reno, Reno, NV. ²University of Alabama, Tuscaloosa, AL.
 Email: bryannabrown98@gmail.com
 (No relevant relationships reported)

The Vestibular/Ocular Motor Screening (VOMS) tool is a common assessment that was specifically designed to evaluate vestibular and/or oculomotor control deficits following sport-related concussion. The only objective component of the VOMS is near point convergence (NPC) distance. This distance is commonly measured from the tip of the nose to the instrument (typically a 14-point font "X" on a tongue depressor) which is brought towards the patient's nose. Unfortunately, without the use of an accommodation convergence ruler, it is possible that NPC may be measured incorrectly. **PURPOSE:** The purpose of this study was to investigate the use of a custom-made accommodation convergence ruler as compared to conventional methods

for measuring NPC on the VOMS in a healthy population. **METHODS:** 12 healthy collegiate female students (average age = 22 years) all with lower than 20/20 vision (corrected and not corrected) and no diagnosed concussion history participated in this study. All participants completed 3 trials of NPC using standardized instructions and 1) traditional tongue depressor with a 14-point font "X" (TRAD) and 2) a custom made NPC accommodation convergence ruler (RULER). The custom ruler was attached to a series of supports that were connected to the ground and leveled prior to each trial. The ruler is placed at the tip of the nose and participants bring a 14-point font dot on a slide toward the bridge of their nose. Between each trial and condition, participants were given 2-mins of rest as needed to reduce ocular fatigue. Each NPC distance were measured by a highly trained rater and averaged for further analysis using a paired t-test. **RESULTS:** The results indicate no significant differences between using the TRAD (average=2.79cm \pm 2.05cm) and the RULER (average=2.12cm \pm 1.64cm; $p=0.17$; Cohen's $d=0.41$). The TRAD had two measurements that were above 5cm, while the RULER measurement had only one above 5cm. **CONCLUSIONS:** Using a more sophisticated device to measure NPC may not directly influence the measurement of NPC as compared to standard conventional methods in an all-female healthy population. Although NPC distance trended lower and had fewer false negatives using the RULER, trained clinicians using standardized instructions may not need to use an accommodation convergence ruler to obtain sufficient measurements.

2843 Board #304 May 29 9:30 AM - 11:00 AM
The Relationship Of Subjective And Objective Sleep Measures In Pediatric Concussion

Julie C. Wilson, Corrine Seehusen, Dennis Coonan, Tim Cuddeback, Gregory Walker, David R. Howell. Children's Hospital Colorado, Aurora, CO.
 (No relevant relationships reported)

BACKGROUND: Sleep problems after concussion may impact recovery. Early research has primarily focused on subjective sleep measures; however, actigraphy data may help objectively understand sleep patterns after pediatric concussion. **PURPOSE:** To determine association between subjective and objective sleep measures among pediatric athletes with concussion. **METHODS:** Pediatric athletes evaluated within 14 days of concussion were given a wrist-worn activity tracker, to be worn full-time, including during sleep. During initial visit and follow up evaluation at clearance for return to play (RTP), athletes completed the Pittsburgh Sleep Quality Index (PSQI). PSQI measures included self-reported sleep duration, time spent in bed, and sleep quality, while activity tracker actigraphy data was used for objective sleep duration, time spent in bed and time spent in each sleep stage. **RESULTS:** A total of 12 individuals (mean age=15.0 \pm 1.8 yrs; 42% female) completed initial concussion evaluation (mean=7.4 \pm 3.3 days post-injury), and follow-up evaluation at RTP clearance (mean=21.7 \pm 18.9 days post-injury). There was no significant difference in amount of sleep recorded using self-reported (7.9 \pm 1.2 hrs) and actigraphy (7.3 \pm 0.7 hrs) measures ($p=0.10$), or for amount of time spent in bed per night (8.8 \pm 1.6 vs. 8.2 \pm 0.7 hrs; $p=0.25$). Self-reported and actigraphy measures were highly and significantly correlated for amount of sleep per night ($r=0.73$; $p=0.04$) but not for amount of time spent in bed ($r=0.59$; $p=0.12$). Participants spent an average of 12 \pm 3% awake, 20 \pm 4% in REM sleep, 51 \pm 4% in light sleep, and 17 \pm 2% in deep sleep per night. Those who reported very good sleep quality on PSQI at RTP clearance visit had significantly more time in deep sleep (17.9 \pm 1.2% vs. 16.0 \pm 0.8% of the night; $p=0.04$) and significantly less time in light sleep (48.4 \pm 1.8% vs. 52.8 \pm 2.9% of the night; $p=0.04$) than those who reported fairly good or fairly bad sleep quality. **CONCLUSIONS:** There was no difference in subjective and objective measures for sleep duration and time spent in bed. Actigraphy data was highly correlated with self-reported measures for sleep duration following concussion. Minor differences in light and deep sleep proportions were present between pediatric athletes who reported very good sleep vs fairly good/ fairly bad sleep quality.

Between Trial Reliability Of The King Devick Test In Female High School Athletes

Brandon D. Spradley¹, Robert L. Herron¹, James P. Toldi², Dani Ellis³, Chelsea L. Best³, Ashley D. Marass², Anthony M. Martino². ¹United States Sports Academy, Daphne, AL. ²University of South Alabama, Mobile, AL. ³Encore Rehab, Mobile, AL.
 (No relevant relationships reported)

National high-school injury-surveillance data has demonstrated the need for continued development of concussion-related safety programs. Of note, in directly-comparable sports, concussion-incidence rates are reported to be higher for female athletes. As such, medical personnel need valid-baseline assessments in order to best serve and protect athletes suspected to have a concussion. **PURPOSE:** To determine the between-trial reliability of the King-Devick Test (KD) as part of a pre-season concussion-safety program in young-female athletes. **METHODS:** Female high-school athletes ($n = 28$, aged 16 \pm 1 years) completed electronic KD baseline assessment on hand-held tablets.

Participants were required to complete two, error-free trials - reported to the nearest 0.0 s. Descriptive data for baseline attempts were computed, mean differences were examined via paired-samples one-tailed *t*-tests, Cohn's *d* effect sizes were considered, and two-way mixed-effects intraclass correlations (ICC) were analyzed. **RESULTS:** The KD test showed strong reliability between trials (Trial 1 = 52.0 ± 7.7 s; Trial 2 = 49.8 ± 8.6 s; single-measure ICC = 0.83; 95% CI 0.66 - 0.92). Furthermore, excellent reliability was observed when KD scores were grouped by Best score and Worst score (Best = 48.7 ± 7.2 s; Worst = 53.2 ± 8.6 s; single-measure ICC = 0.94; 95% CI 0.87 - 0.97). Paired-samples *t*-test identified small or moderate differences between both pairings respectively (Trail 1 vs. Trial 2, $p = 0.01$, $d = 0.27$; Best vs. Worst, $p < 0.001$, $d = 0.57$). Most participants (75%) recorded their Best score on Trial 2. **CONCLUSIONS:** Strong-to-excellent reliability was observed among trials in this population of young-female athletes. However, these data demonstrate a need for further investigations that address the potential need for multiple baseline testing sessions in order for practitioners to best serve female, high-school athletes.

Case Study: Shear Wave Tensiometry Detects Asymmetry In Achilles Loading During Gait After Unilateral Rupture

Jack A. Martin¹, Todd J. Hullfish², Kathryn M. O'Connor², Josh R. Baxter², Darryl G. Thelen¹. ¹University of Wisconsin-Madison, Madison, WI. ²University of Pennsylvania, Philadelphia, PA.
Email: jamartin8@wisc.edu
(No relevant relationships reported)

Achilles tendon ruptures are debilitating injuries that lead to long-term functional deficits in two thirds of patients. Shear wave tensiometry is a non-invasive technique for measuring tendon loading during functional activities by inducing waves traveling along the tendon and measuring their propagation speed. Tensiometers have the potential to be implemented in clinical settings to objectively track tendon loading to assist in clinical decision-making. **Purpose:** To determine whether shear wave tensiometry can detect abnormalities in tendon loading during recovery following Achilles tendon rupture and repair. **Methods:** Tensiometers were placed bilaterally on the Achilles tendons of one subject who had undergone surgical repair of a unilateral Achilles tendon rupture 14 weeks prior (M, 87.6 kg, 193 cm) and two control subjects (M, 75.0 kg, 188 cm; M, 100.0 kg, 185 cm). Each subject first performed isometric ankle plantarflexion contractions while wave speed and joint torque were measured. Tendon force was estimated from torque by assuming a normative 5 cm Achilles moment arm. Isometric data were used to calibrate a linear model for predicting tendon force from wave speed squared. The subject then walked on a treadmill (patient: 1.25 m/s; controls: 1.50 m/s) while Achilles tendon wave speed was recorded bilaterally. Plantarflexor impulse was calculated by integrating predicted tendon force over each stance phase. **Results:** We estimate that the patient produced a 40% lower plantarflexor impulse on the injured side (4.8 ± 0.4 N·s·kg⁻¹; mean ± SD) compared to the healthy side (8.0 ± 1.0 N·s·kg⁻¹), while the side-to-side differences for control subjects were 5% (8.4 ± 0.4 N·s·kg⁻¹ vs. 8.0 ± 0.2 N·s·kg⁻¹) and 2% (10.7 ± 0.7 N·s·kg⁻¹ vs. 10.5 ± 1.0 N·s·kg⁻¹), respectively. **Conclusion:** Tensiometer data show that the patient adopted a gait pattern that underloaded the healing tendon. This is important to consider given that early loading exposure may be an important determinant of long-term healing and structure of the repaired tissue. This study establishes the feasibility of using shear wave tensiometry to quantify tendon load during clinical assessments of patients with tendon injuries, which is an unmet clinical need. Supported by the Thomas B. and Jeannette E. Laws McCabe Fund and the Wisconsin Alumni Research Foundation.

Feasibility Of Open Low-field MRI Measurements In Adolescent Athletes With Spondylolisthesis

Theresa Anna Joost, Pia Brecht, Frank Mayer, Michael Cassel.
University of Potsdam, Potsdam, Germany.
Email: joost.theresa@gmail.com
(No relevant relationships reported)

Spondylolysis and spondylolisthesis are common findings in adolescent athletes (AA), potentially leading to load-dependent pain and segmental spine instability. In diagnostics, supine MRI is frequently used to visualize the lumbar spine structures. However, upright MRI procedures have been shown to be of clinical value in the detection of load-dependent changes in parameters.

PURPOSE: To determine the feasibility of upright compared to supine MRI measurements to determine characteristics of the lumbar spine in AA with spondylolisthesis. **METHODS:** Ten AA (n=10; m/f: 4/6; 14.5 ± 1.7 ; 163 ± 7 cm; 52 ± 8 kg) from various sports, diagnosed with spondylolisthesis grade I-II Meyerding confirmed by x-ray in standing lateral view, were included. Open low-field MRI images (0.25 Tesla) in upright (82°) and supine (0°) position were evaluated by two observers. Medical imaging software was used to measure the anterior translation (AT, mm), lumbosacral joint angle (LSJA, °) and lordosis angle (LA, °). Reliability was analyzed by the intra-rater correlation coefficient (ICC) and standard error of measurements (SEM). **RESULTS:** Due to motion artifacts during upright position, measures of three participants had to be excluded. Between observers, AT ranged from 4.2 ± 2.7 mm to 5.5 ± 1.9 mm (ICC=0.94, SEM=0.6mm) in upright and from 4.9 ± 2.4 mm to 5.9 ± 3.0 mm (ICC=0.89, SEM=0.9mm) in supine position. LSJA varied from $5.1 \pm 2.2^\circ$ to $7.3 \pm 1.5^\circ$ (ICC=0.54, SEM=1.5°) in upright and from $9.8 \pm 2.5^\circ$ to $10 \pm 2.4^\circ$ (ICC=0.73, SEM=1.1°) in supine position. LA differed from $58.8 \pm 14.6^\circ$ to $61.9 \pm 6^\circ$ (ICC=0.94, SEM=1.19°) in upright and from $51.9 \pm 11.7^\circ$ to $52.6 \pm 11.1^\circ$ (ICC=0.98, SEM=1.59°) in supine position. **CONCLUSIONS:** Determination of AT and LA showed good to excellent reliability in both, upright and supine position. In contrast, reliability of LSJA had only moderate to good correlation between observers and should therefore be interpreted with caution. However, motion artifacts should be taken into consideration during upright imaging procedures.

2847 Board #308 May 29 9:30 AM - 11:00 AM

Patient Adherence Impacts The Effectiveness Of Neuromuscular Electrical Stimulation Treatment After Articular Cartilage Knee Surgery

Caitlin EW Conley¹, Jennifer S. Howard², Emily V. Dressler³, Anne Olson¹, Christian Lattermann⁴, Carl G. Mattacola⁵.
¹University of Kentucky, Lexington, KY. ²Appalachian State University, Boone, NC. ³Wake Forest, Winston Salem, NC. ⁴Brigham & Womens Hospital, Harvard, Boston, MA. ⁵University of North Carolina Greensboro, Greensboro, NC.
(No relevant relationships reported)

PURPOSE: Articular cartilage patients commonly display persistent strength deficits despite extensive rehabilitation prescriptions. The purpose was to evaluate the effectiveness of a postoperative home based neuromuscular electrical stimulation (NMES) treatment on clinical outcomes. **METHODS:** Eligible patients were consented preoperatively and randomized to a 12-week postoperative home based NMES program or the standard quadriceps exercise program, both in conjunction with formal physical therapy. Patients completed patient reported outcomes (PROs)(KOOS, VAS) and isometric quadriceps strength testing (peak torque and limb symmetry index (LSI=involved peak torque/uninvolved peak torque)) preoperatively and 3-months (3m) postoperatively. The NMES group's treatment adherence was measured via an internal monitor. An RM-ANOVA was used to compare each dependent variable between baseline and 3m postoperative.

RESULTS: 25 patients (11F, 30 ± 10yrs, BMI: 28.15 ± 5.97) were enrolled. The surgical limb peak torque strength ($p < 0.00$) and the LSI ($p < 0.00$) decreased significantly, while KOOS pain statistically improved ($p = 0.02$) (Table 1). At 3m post-operative, there were no statistical differences between groups for any dependent variable (Table 1). Patients in the NMES group completed $25.49 \pm 25.32\%$ of the prescribed treatment. Comparing the 3m strength values between two moderately adherent patients (completed 50-80% of the treatment) and the control group we see a trend favoring NMES (NMES: 1.33 Nm/kg, control: 0.92 Nm/kg).

CONCLUSIONS: Overall patients experienced a decrease in quadriceps strength but an improvement in KOOS pain. While there was a trend with 3-month quadriceps strength values being higher in patients who were moderately adherent, the overall majority of the patients were not adherent. Thus, due to the lack of adherence, an NMES home treatment program may be an ineffective treatment option for articular cartilage knee surgery patients.

Table 1: Repeated measures ANOVA results for all outcome variables

	Baseline N=25	3-Months N=25	p-value
Number of Participants

2848 Board #309 May 29 9:30 AM - 11:00 AM The Relationship Between Isokinetic Hamstring To Quadriceps Strength Ratio And A Battery Of Exercise Field Tests In Healthy Women

Chad Sutherland, George Taouil, Kevin J. Milne. *The University of Windsor, Windsor, ON, Canada.*
Email: chads@uwindsor.ca

(No relevant relationships reported)

Knee injuries are one of the most common ball sport related injuries and cause hundreds of millions of dollars in rehabilitation costs annually. Girls and women are 4-9 times more likely to experience a knee injury compared to boys and men, and typically suffer more severe knee injuries. Strength imbalance of the hamstrings and quadriceps muscles during complex sport movements and/or as a result of fatigue may contribute to knee injury occurrence. **PURPOSE:** This study attempted to predict the ratio of isokinetic muscular strength of the hamstring and quadriceps muscles from a battery of exercise field tests both before and after fatigue. **METHODS:** Women (n = 29) were recruited from the University of Windsor and completed an exercise field testing protocol consisting of a 20m forward sprint, 20m backward sprint, 5-10-5 agility test, single leg hop for distance, side hop, vertical jump, and eccentric Nordic hamstring curl (NHC), as well as an isokinetic dynamometer protocol to obtain muscle peak torques (PT) and hamstring to quadriceps PT ratios (HQR), before and after a 45 minute simulated exercise protocol. **RESULTS:** PT ($F(1,228) = 27.678, p=0.00$) and HQR ($F(1,871,321.889) = 15.689, p=0.00$) decreased following the exercise protocol. Further, the battery of field tests were able to predict $HQR_{con/con}$ at 60° in the non-dominant limb ($F(3,24) = 4.42, R^2 = 0.622, p = 0.015$), with a combination of the speed tests (ST), jump tests (JT) and NHC in the final model, but not changes that occurred because of the exercise protocol. **CONCLUSION:** HQR may predict knee injury risk, and consequently, the field tests employed in the current study could be used by strength and conditioning specialists to assess risk without the need for more expensive equipment. However, HQR should be reassessed as a method for knee injury prediction with respect to more functional models, at specific joint angles, and in relation to fatigue. Further, future studies should employ additional field tests that may strengthen the association with risk.

2849 Board #310 May 29 9:30 AM - 11:00 AM Training Dose And Effect- Response Relationship Of Motor Control Stabilization Exercises On Pain And Disability In Chronic Non-specific Low Back Pain Patients: A Systematic Review With Meta-regression

Juliane Mueller¹, Daniel Niederer². ¹Trier University of Applied Sciences, Trier, Germany. ²Goethe University Frankfurt, Frankfurt am Main, Germany.

Email: ju.mueller@hochschule-trier.de

(No relevant relationships reported)

Motor control stabilization exercise (MCSE) is evident for the management of chronic non-specific low back pain (LBP). The optimal dose for the maximal treatment success-response relationship is, thus, still unknown.

PURPOSE: To systematically review the evidence for a dose-response relationship of MCSE on pain and disability in chronic non-specific LBP patients.

METHODS: A systematic review with meta-regression was conducted. We searched in relevant scientific databases (Pubmed (Medline), Web of Knowledge, Cochrane). The eligibility criteria for the studies were: RCTs and CTs on chronic (≥ 12 weeks) non-specific LBP patients, written either in English or German and adopting a longitudinal MCSE intervention with at least one pain intensity and/or disability

outcome assessment. Meta-regressions (dependent variable = effect sizes (Cohens d) of the interventions (once for pain and once for disability), independent variable = training characteristics (duration, frequency, time per session)) were conducted to reveal the optimal dose required for MCSE therapy success.

RESULTS: From the 3,415 studies initially selected, 46 studies on n = 2,661 LBP patients were included in the analysis. N = 1,220 patients received MCSE; the training duration was 6.4 ± 2.3 weeks and the training frequency was 3.4 ± 2.0 sessions per week with a mean training time per session of 44.2 ± 17.7 min. The meta-regressions' mean effect size was $d = 1.7$ for pain and 2.1, for disability, respectively. Total R^2 was 0.34 and 0.38. Moderate quality evidence ($R^2 = 0.136$) revealed that a training duration of 20 to 30 minutes elicited the largest effect (both in pain and disability, logarithmic association). Low quality evidence ($R^2 = 0.202$) revealed that training 3 to 5 times per week led to the largest effect of MCSE in chronic non-specific LBP patients (inverted U-shaped association). Training duration showed no systematic variance explanation on the effect sizes.

CONCLUSIONS: In non-specific chronic LBP patients, MCSE with a training frequency of 3 to 5 times per week (Grade C recommendation) and a training time per session of 20 to 30 minutes (Grade A recommendation) elicited the largest effect on pain and disability. Future work may focus on the definition of a minimum dosage for therapy success.

2850 Board #311 May 29 9:30 AM - 11:00 AM Comparison Of Quadriceps Thickness And Strength, And Knee Function Between Individuals With Acl Reconstruction And Healthy Individuals

VOLGA BAYRAKCI TUNAY, GULCAN HARPUR, SERDAR DEMIRCI, RUHI SOYLU. *Hacettepe University, Ankara, Turkey.*

Email: volgatunay@hacettepe.edu.tr

(No relevant relationships reported)

PURPOSE: To compare quadriceps thickness and strength, and self-reported knee function between individuals with ACL reconstruction (ACLR) and healthy individuals **METHODS:** 24 individuals who returned to sport after ACLR and 18 healthy individuals were included in this study. The ACLR group were divided into 2 groups according to time after surgery: <2 years after surgery (n=12) and >5 years after surgery (n=11). Vastus medialis obliquus (VMO), vastus medialis (VM), rectus femoris (RF) and vastus lateralis (VL) muscle thickness were measured by ultrasound. Quadriceps peak torque at 60°/s and 180°/s were measured by isokinetic system, IKDC and KOOS scores were used to evaluate self-reported knee function. One way ANOVA was performed for statistical analysis

RESULTS: VMO and VM muscle thickness were different between groups ($p=0.01, p=0.003$). ACLR group whose time after surgery <2 years had thicker VMO and VM compared to ACLR group whose time after surgery >5 years ($p=0.02$) and healthy group ($p=0.02$). There was no difference between groups in RF and VL muscle thickness ($p>0.05$). Quadriceps strength was also greater in ACLR group whose time after surgery <2 years at 60°/s ($p=0.005$) and 180°/s ($p<0.001$). IKDC and KOOS scores were greater in healthy group and ACLR group whose time after surgery <2 years compared to ACLR group >5 years after surgery ($p<0.05$).

CONCLUSIONS: Time after surgery seems to affect quadriceps size and function, and self-reported knee function in individuals with ACLR. Better outcomes in ACLR groups whose time to surgery lower than 2 years may be due to post-operative rehabilitation effect. Decrease in self-reported knee function in long term after ACLR may not related to quadriceps muscle size and strength.

2851 Board #312 May 29 9:30 AM - 11:00 AM ACL Tears Aren't Just For Girls: The Role Of Age In Predicting Pediatric ACL Injury

Cordelia W. Carter, Debra Sala, Andrew Michalowitz. *NYU-Langone Medical Center, New York, NY.*

(No relevant relationships reported)

Purpose: While it is well-documented that females have a higher risk of anterior cruciate ligament (ACL) injuries than males, the role of age in mediating this injury risk has not been explored. The purpose of this study was to characterize the relationship between age and sex in predicting ACL injury in the pediatric population. The primary hypothesis was that prepubescent males are more likely to sustain an ACL injury than prepubescent females.

Methods: Data were collected from The Statewide Planning and Research Cooperative System (SPARCS) database for the state of New York from 1996-2016. The database was queried for patients ≤ 19 years who had been diagnosed with an ACL tear using the ICD-9 code 844.2 or the ICD-10 codes S83.512A/ S83.511A/ S83.519A. Patient age and sex at time of diagnosis with ACL injury were recorded. Chi square analysis was used to compare the frequency of ACL injury for the categorical variables age and sex, with statistical significance set at $p<0.05$.

Results: During the study period, 20,128 patients aged ≤ 19 years old were diagnosed with an ACL tear (10,830 males, 9,298 females, male:female = 1.2:1).

129 patients <12 years sustained an ACL tear (85 males, 44 females, male:female = 1.9:1), while 19,999 patients aged 12-19 years sustained an ACL tear (10,745 males, 9,254 females, male:female = 1.2:1). Chi-square analysis demonstrated a significant relationship between sex and age group ($p < 0.006$). Additional analysis revealed that females were most at risk for ACL injury from ages 12-16 years, with 2135 males and 2994 females sustaining ACL injuries in this group, (male:female = 1:1.4, $p < 0.005$). Conclusion: The results of this study confirm the hypothesis that prepubescent males (those <12 years) are more likely to sustain an ACL injury than same-aged female peers. While a patient's sex plays an important role in determining risk for ACL injury – in addition to other factors such as sport played and previous injury history – the relative risk changes throughout the pediatric and adolescent years, with males being more likely to sustain an ACL injury in the prepubertal period while females are more likely to sustain ACL injury in the pubertal period. Understanding this allows us to better individualize screening and prevention programs for ACL injury in pediatric athletes.

 (No relevant relationships reported)

A hamstring to quadriceps strength ratio (H:Q) $\geq 60\%$ and limb symmetry index (LSI) $\geq 90\%$ during unilateral assessments of strength and function have been used as return to play (RTP) benchmarks following anterior cruciate ligament reconstruction (ACLR). PURPOSE: Determine the relation between H:Q and single (SH), triple (TH), triple cross-over (CH), and 6 m timed (6H) hopping assessment performance (e.g. distance achieved or time to complete). METHODS: Sixty-four ACLR patients (34 males: 20.92 \pm 7.93 y, 1.83 \pm .09 m, 88.34 \pm 17.36 kg; 30 females: 17.63 \pm 2.84 y, 1.67 \pm .07 m, 63.32 \pm 7.25 kg) 26.01 \pm 9.57 wks post-surgery volunteered to participate. Participants completed maximal voluntary isokinetic knee extension and flexion strength testing on the injured leg (IL) and non-injured leg (NIL) through a range of 20° to 90° of knee flexion at 60°·s⁻¹, 180°·s⁻¹, and 300°·s⁻¹. Participants were stratified into groups based on whether they obtained $\geq 60\%$ H:Q (PASS) or $< 60\%$ H:Q (FAIL) for each speed. Three trials of each hop test were performed on IL and NIL. The mean hop performance on each leg per test was normalized to participant height. Pearson correlations were used to explore the relation between hopping performance and H:Q. T-tests were used to assess for the effect of group on hopping performance. Significance was set at $p < 0.05$ RESULTS: Males demonstrated negative correlations for IL between SH and H:Q at 300°·s⁻¹ ($r = -.49$ [-.71 -.18], $p = .003$), TH and H:Q at 60°·s⁻¹ ($r = -.80$ [-.80 to -.38], $p < .001$), and TH and H:Q at 180°·s⁻¹ ($r = -.63$ [-.76, -.27], $p < .001$). Males also demonstrated negative correlations for NIL between TH and H:Q at 60°·s⁻¹ ($r = -.41$ [-.65 to -.08], $p = .018$) and 180°·s⁻¹ ($r = -.42$ [-.64, -.05], $p = .027$). No significant correlations between H:Q and hopping performance were identified in females. At 300°·s⁻¹, FAIL males had greater normalized SH scores for both IL (.78 \pm .18 vs. .89 \pm .15; $p = .04$) and NIL (.82 \pm .15 vs. .91 \pm .14; $p = .06$). CONCLUSION: These results suggest a negative relation between H:Q and functional performance post-ACLR. H:Q $< 60\%$ may indicate superior quadriceps strength which leads to a greater internal knee extension moment capacity and improved hopping performance. However, achieving an H:Q above an acceptable threshold may be protective and aid in knee joint translation stability.

Influence Of Gender, Body Mass Index, And Foot Length On Foot Strength

Karen Stevens, Deidra Fabbri, Christopher Falciano, Sarah Herberg, Jessica Kras, Allison Pohl, Alec Tessler. *Rosalind Franklin University, North Chicago, IL.*
 Email: karen.stevens@rosalindfranklin.edu
 (No relevant relationships reported)

PURPOSE: Foot and ankle musculature provide dynamic support during athletic activities. Impaired foot strength may impact balance, re-injury, and alter foot function. Accurate measurement of foot strength is needed to better determine if impaired strength impacts pain, function, and rehabilitation. Foot strength measurements, though, may be influenced by factors such as gender, body mass, or foot structure. Additionally, foot strength measures have been observed to be different in sitting versus standing. The purpose of this study was to determine if there is a difference in foot strength measured in sitting and standing between males and females, and if there is a relationship between foot strength and body mass index (BMI) or foot length. METHODS: Twenty four participants (Mean Age = 25 years; Mean BMI = 24.9), including 12 males and 12 females, completed the study. After consenting, participants completed a questionnaire about activity level and injury history. Participants' height, weight, and foot length were measured. In both the sitting and standing positions,

participants pulled on a towel with their toes as a dynamometer measured maximum force for each foot. Three trials were measured for each foot in each position, and the mean of the three trials used in data analysis. Order of testing was randomized. Paired t-tests and effect sizes (Cohen's d) were used to examine differences between gender and across conditions. Correlations were used to assess the influence of BMI and foot length on foot strength for both conditions.

RESULTS: In comparison to females, male foot strength was greater in both sitting and standing (both $d = .5$), but only statistically different in sitting ($p < 0.05$). Foot length was significantly correlated to strength (left: $p < 0.01$; right $p < 0.05$) in sitting, but not in standing. Body mass index was not significantly correlated to strength.

CONCLUSIONS: Gender and foot length influence strength measurements conducted in a sitting position. Body mass index does not influence foot strength measurements in sitting or standing. Further investigation about differences in foot strength measured in sitting versus standing is needed.

Cross-education Effects On Rotator Cuff Strength Recovery After Bankart Repair

Taha I. Yildiz, Serdar Demirci, Egemen Turhan, Durmus A. Ocguder, Gazi Huri, Irem Duzgun. *Institution of Health Sciences, Ankara, Turkey.*
 Email: yldztahaibrahim@gmail.com
 (No relevant relationships reported)

Enhancing the rotator cuff (RC) strength is the primary goal of the rehabilitation after Bankart repair. Cross-education (CE) could be a promising treatment where the strengthening of the injured limb could not be possible or may be detrimental. However, there is no information about CE effect on RC strength recovery after Bankart repair.

PURPOSE: The aim of this study was to investigate effects of CE on RC muscle strength recovery in patients with Bankart repair.

METHODS: Eighteen patients with Bankart repair included to the study. Patients were randomly allocated into two groups. Patients in Group-1 (n=8, age: 21.7 \pm 3.2 years, body mass index: 25.4 \pm 2.2 kg/m²) received a standard 12-week-rehabilitation program after the surgery. Patients in Group-2 (n=10, age: 24.4 \pm 5.4 years, body mass index: 25.6 \pm 4.2 kg/m²) received the same rehabilitation program but also attended RC concentric strengthening program of the non-operated side with isokinetic dynamometer twice in a week between post-operative 2-12 weeks. The concentric isokinetic training was conducted on the scapular plane and at 45° of shoulder abduction. The training consisted of 3 sets of 10 repetitions for internal and external rotators and performed at 60°/sec angular velocity. On both groups, the concentric internal and external rotator (IR and ER) strength was measured pre-operatively and at post-operative 12 and 24 weeks. The measurements were conducted on the scapular plane using at 60°/sec and 180°/sec angular velocities on both shoulders. Repeated measures of ANOVA was used for statistical analysis.

RESULTS: The main effect of time was significant on patients with Bankart repair. Compared to pre-operative time the RC strength decreased at post-operative 12 weeks and recovered at post-operative 24 weeks ($p < 0.05$). There were no group by time interaction ($p > 0.05$).

CONCLUSIONS: The results of this study demonstrated that standard Bankart rehabilitation improved rotator cuff strength recovery but adding cross-education had no beneficial effect on recovery after Bankart repair.

Impact Of Fifa 11+ Program On Acl Injury Rates In Collegian Female Rugby Players

Jeffrey Laurence Fairley¹, Evan Wollen², Andrea Gomez¹, Natalie Vega¹, Wesley Oaties¹. ¹Western University of Health Sciences, Pomona, CA. ²Claremont McKenna College, Claremont, CA.
 Email: jfairley@westernu.edu
 (No relevant relationships reported)

This is a preliminary study on the impact of a FIFA 11+ training program for collegiate female rugby players at a local college. The FIFA 11+ was developed to prevent lower extremity injuries among soccer athletes. Retrospective analysis of injured Rugby athletes suggested the non-contact (NC) ACL injuries were similar to soccer related NC ACL injuries. Given the success the FIFA 11+ program on injury reduction, it was suggested as an intervention. PURPOSE: The purpose is to investigate the effects of the FIFA 11+ program on reducing NC ACL injuries in collegiate female athletes. METHODS: Historical injury data was obtained. FIFA 11+ training program was implemented at the start of the season and continued as part of the pre-practice/game warm up. Injury data was logged throughout the rugby season of approximately 25 weeks between September and May. A comparison was made between 2016 season's injuries to the 2017 and 2018 years. RESULTS: In the 2016 season prior to intervention, 9 athletes were injured/unable to participate because of rugby related musculoskeletal injuries with 3 NC ACL injuries. In the two seasons that the FIFA 11+ program was

implemented, 2017 and 2018, NC ACL injuries were reduced to 0. In the 2017 season, 9 athletes were injured specifically, 3 concussions, 1 (Contact) ACL injury, and 5 other injuries. In 2018, ACL injuries were reduced to 0, while concussions (5) and fractures (3), and other injuries limited participation. Twice a week, 2-hour practice sessions and games were included to estimate a team NC ACL injury rate per activity hour ratio. In 2016 the ratio was 3/3000 hrs. There were no NC ACL injuries in both 2017 (0/3472 hrs) and 2018 (0/3900 hrs) together equal 0/7372 hrs. If the injury rate from 2016 were maintained, NC ACL injuries would be predicted to be >7. **Conclusions:** This preliminary study suggests the FIFA 11+ may have broader application to other field sports and that specific training programs may reduce the incident of ACL injuries in Rugby athletes.

Yr / Players	Games (estimated 2 hrs/game)	Weeks of participation	Typical Practice Hrs per week	Estimated Total Team participation hrs	NC ACL/ hrs
2016 / 25	10	25	4	3000	3/3000
2017 / 28	12	25	4	3472	0/3472
2018 / 30	13	26	4	3900	0/3900

Does Immobilization Period Affects The Functional Outcomes After Bankart Repair?

Irem Duzgun, Taha I. Yildiz, Gazi Huri, Dilara Kara, Ceyda Sevinc, Egemen Turhan, Serdar Demirci, Leyla Eraslan, Elif Turgut, Ozgur A. Atay. *Institution of Health Sciences, Ankara, Turkey.*

Email: iremduzgun@yahoo.com
(No relevant relationships reported)

There is no consensus about the absolute immobilization time period and whether the rehabilitation should start in the first or in the third week after Bankart Repair.

PURPOSE: The aim of this study was to compare the clinical outcomes of 1 and 3 weeks of absolute immobilization time after the surgery and evaluate their effects on recurrent instability. **METHOD:** Forty-two patients with arthroscopic Bankart surgery were included to the study. Patients were randomly allocated into two groups. One week of absolute immobilization was performed to the patients in group-1 (n=21, age:24.7±7.1, BMI: 25.3±3 kg/cm²) and 3 weeks of absolute immobilization was performed to the patients in group-2 (n=21, age: 22.1±6.7 years, BMI: 24.8±2.8 kg/cm²). All of the patients come to the clinic once in a week and performed supervised exercise program and the rehabilitation program was progressed. They were also prescribed home exercise program. Shoulder ROM, pain level and shoulder function were assessed, according their groups at the first or third weeks, 4, 8 and 12 weeks of post-operative period. The pain level during resting, activity and at night was assessed with VAS. Shoulder ROM was assessed with standard goniometer and shoulder function was assessed using ASES questionnaire. At the average of 30. weeks after the surgery, it was questioned whether there was a re-dislocation. The demographics of the patients on both groups were analyzed with student t test. Two-way repeated measures ANOVA was used for the statistical analyses. **RESULTS:** There were no significant the "Group*time" interactions for pain at rest and activity and flexion, abduction, external rotation, internal rotation angles (p>0.05). The main effect of time was significant at rest and activity pain and all ROM measurements (p<0.05). There was a significant "Group*Time" interaction for pain at night (p<0.05). Pain at night was higher in the group-1 at post-operative 1 and 4. weeks compared to group-2. There were no statistically significant differences between the two groups in shoulder function at post-operative 12 weeks (p>0.05) and 30 weeks (p>0.05). One patient had re-dislocation in the group-2. **CONCLUSION:** One or three weeks of absolute post-operative immobilization period does not differ in terms of functional outcomes on patients with Bankart repair.

Correlation Of Fms, Ybt With The Sports Injuries Of Elite Fencing Athletes

Guohan Wang, Minjia wang, Zhengyang Ye, Haoyu Chen, Youwei Xiong, Yufeng Lu. *Chengdu Sport University, Chengdu City, Sichuan province, China.*

Email: ooreowang@163.com
(No relevant relationships reported)

Objective: To analyze the correlation between Functional Movement Screen(FMS), Y-Balance Test(YBT) and the Sports Injuries of different sword-type elite fencing athletes during the 2018-2019 World Cup season.

Methods: During the 2018-2019 fencing World Cup, recruited three groups of elite fencing athletes. Epee group (age:22.50±6.50years, 8males and 10 females), Foil group (age:21.00±9.20 years, 8 females) and Sabre group (age: 20.56± 5.08years, 9 males and 10 females), a total of 45 Chinese elite fencing athletes. Before the World Cup season, FMS (six movements), double upper quarter(UQ) limbs' YBT (Anterior, A; Posteromedial, PM; Posterolateral, PL) and double upper quarter(UQ) limbs' YBT(A, PM, PL) were tested to assess the movement function. After the World Cup season, athletes were classified as having sports injuries during the season in 6 levels (mild to severe trauma) according to the Abbreviated Injury Scale(AIS) Scores: Spearman's correlation analysis methods were used to analysis the relationship of FMS score, UQYBT, LQYBT with the different sword species.

Results: We found FMS score, YBT were related to the sports injuries indifferent types of fencing athletes: (1)FMS score: ①Epee group: FMS(14.89±7.0)and AIS's correlation coefficients(r=-0.223, P<0.05); ②Foil group's FMS(15.71±13.24) and AIS's correlation coefficients(r=-0.436, P<0.05); ③Sabre group's FMS(15.67±6.82) and AIS's correlation coefficients(r=-0.352, P<0.05) . the higher the FMS score, the lower the injury risk. (2) UQ-YBT: Epee group's (A=89.09±30.54) and AIS's correlation coefficients(r=-0.926, P<0.05). The higher the YBT's relative anterior distance, the lower injury risk. Epee group (P<0.05). (3)LQ-YBT: Epee group's (A=66.32±33.96) and AIS's correlation coefficients(r=-0.672, P<0.05); Sabre group's LQ-YBT(A=62.65±26.49) and AIS's correlation coefficients(r=-0.543, P<0.05); The higher the YBT's relative anterior distance, the lower of injury risk (P<0.05).

Conclusion: For elite fencing athletes, FMS score is highly related with the sports injury; YBT's was only related to of the Epee group and the Sabre group, and was not significantly related to the flower sword group; Future randomized, controlled studies are needed to confirm these findings.

Knee Strength Recovery And Factors Affecting Knee Strength After Anterior Cruciate Ligament Reconstruction

Dilara Kara, Serdar Demirci, Taha Ibrahim Yildiz, Ceyda Sevinc, Burak Ulusoy, Leyla Sumeyye Eraslan, Gulcan Harput, Volga Bayrakci Tunay. *Hacettepe University, ANKARA, Turkey.*

Email: dilaradonder@gmail.com
(No relevant relationships reported)

PURPOSE: To evaluate the recovery of knee extension and flexion strength after anterior cruciate ligament reconstruction (ACLR) and to identify the factors affecting knee strength at 6 months after ACLR. **METHODS:** Thirty-seven patients [31 male, 6 female; age: 22.8±8.0 years, body mass index (BMI): 22.4±4.1 kg/m²] who underwent ACLR with hamstring tendon autograft were included in this study. The patients attended a standardized rehabilitation program after surgery. Isokinetic concentric strength of the quadriceps and hamstring muscles at 60°/s were performed pre-operatively and at 3, and 6 months post-operatively. The quadriceps strength index (QSI) and hamstring strength index (HSI) were calculated by normalizing the peak torque of the involved leg with the uninvolved leg. Repeated-measures ANOVA was used to evaluate strength changes over time. The multiple linear regression analysis was used to identify independent predictors (age, BMI, preoperative knee muscle strength) of QSI and HSI at 6 months after surgery. **RESULTS:** For the QSI, significant differences were identified among the time points ($F(2,44)=9.72, p<0.001$). Quadriceps strength was greater at 6 months when compared with pre-operatively and (p<0.001) and at 3 months post-operatively (p<0.001). For the HSI, significant differences were identified among the time points ($F(2,44)=4.27, p=0.03$). Hamstring muscle strength was significantly lower at 3 months post-operatively when compared with pre-operatively (p<0.001) and it was greater at 6 months when compared with 3 months post-operatively (p<0.001). At 6 months after ACLR, 40.5% of participants demonstrated greater than 90% for QSI, 48.6% demonstrated greater than 90% for HSI. The multiple linear regression analysis showed that the age and BMI were associated with the QSI (p<0.001, $R^2=0.47$) but not associated with HSI at 6 months after surgery. **CONCLUSION:** This study showed that there was a gradual increase in quadriceps strength from preoperative to 6 months after ACLR. However, hamstring strength decreased at 3 months post-operatively and reached preoperative level at 6

months after ACLR. The most important finding of this study was that younger age and lower body mass index were related with better quadriceps strength at 6 months after surgery.

Sex Differences In Patient Reported Outcomes 6 Months Following Acl Reconstruction

Emily Kidwell, Cale Jacobs, Mary Lloyd Ireland, FACSM, Darren Johnson, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.*

(No relevant relationships reported)

Evidence indicating the important role psychological factors contribute to patient reported outcome (PROs) post anterior cruciate ligament reconstruction (ACLR) has been growing over the last decade. However, it is unclear whether sex-specific differences in psychological profile exist in ACLR recovery. Determining the potential psychological differences between sexes has important implications on the development of targeted intervention strategies post ACLR. **PURPOSE:** To determine whether sex differences in PROs exist at six months following ACLR.

METHODS: Forty-one subjects (23 F, BMI 24.0 ± 3.5 , Age 19.2 ± 5.9 , Tegner 8.8 ± 1.2) six months post ACLR completed PRO questionnaires. Subjects were administered the ACL-Return to Sport after Injury Scale (ACL-RSI), the Knee Self-Efficacy Scale (K-SES), and the Psychological Readiness to Return to Sport Scale (I-PRRS). Independent samples t-tests were used to compare PRO responses between males and females.

RESULTS: No significant differences were observed between male and female demographic information ($p > 0.05$). Significant differences were observed between male and female responses. Males reported higher scores on the ACL-RSI (M: 7.63 ± 1.43 , F: 5.46 ± 2.17 ; $p = 0.004$, Cohen's $d = 1.21$), K-SES8 (M: 8.88 ± 0.85 , F: 7.53 ± 2.11 ; $p = 0.001$, Cohen's $d = 0.88$), and I-PRRS (M: 51.58 ± 6.22 , F: 36.17 ± 13.37 ; $p < 0.001$, Cohen's $d = 1.54$) when compared to females.

CONCLUSIONS: These results show that, six months following ACLR, males have significantly higher knee-function self-efficacy, as assessed by K-SES, I-PRRS and ACL-RSI responses show that males are more psychologically ready to resume sports participation. These results show a discrepancy between male and female psychological response following ACLR, which should be a consideration for re-injury risk. While most patients are cleared to return to activity six to nine months post ACLR, there is a lack of consideration for patient's psychological readiness at the time, for both sexes. If females are returning to sports before being psychologically ready, they are likely to be hesitant and less confident in game situations, contributing to injury risk. Future work is needed to determine if psychologically-focused rehabilitation programs are needed to potentially reverse the reported sex differences.

Standardized PRP Preparation And Associated Outcomes For Knee Oa

mike baria, robert Magnussen, meghan Miller, William Vasileff, James Borchers, FACSM. *The Ohio State University Sports Medicine, Columbus, OH.* (Sponsor: James Borchers, FACSM)
Email: michael.baria@osumc.edu

Reported Relationships: M. baria: Other (please describe); Educational grant received from Arthrex for research.

PURPOSE: To describe a standard preparation method and clinical outcomes using the Angel concentration system (Arthrex; Naples, FL) for knee OA and develop a regression model to determine which clinical variables influence outcome.

METHODS: A review of the medical record was performed on 134 cases of patients who underwent PRP injections for knee OA. Ninety knees (65 patients) were included. All patients had blood processed at 0% hematocrit using the concentration system. International knee documentation committee (IKDC) subjective scores completed at baseline and 3 months were collected and analyzed.

RESULTS: Overall, IKDC score improved from 42.3 ± 14.1 pre-injection to 59.7 ± 17.5 at 3 months post-injection ($p < 0.001$). Of the 90 knees injected, 57% met criteria for a positive response at 3 months with an average final IKDC score of 66.5 ± 15.0 ($\Delta 24.7 \pm 10.9$). Increased patient age ($p = 0.008$) and body mass index ($p = 0.008$) were associated with lower three month IKDC scores. **CONCLUSIONS:** A single PRP injection created at the 0% hematocrit setting yielded a positive response exceeding the minimum clinically important difference in 57% patients with knee OA. Increased patient age and BMI are associated with lower patient-reported outcomes at three month post-injection.

2862 Board #323 May 29 9:30 AM - 11:00 AM

The Use Of Ultrasound Imaging In Assessing Ucl Width For Asymptomatic College Female Golfers

Shawn D. Felton, Arie J. van Duijn, Jacqueline van Duijn, Mitchell L. Cordova, FACSM. *Florida Gulf Coast University, Fort Myers, FL.* (Sponsor: Mitchell L. Cordova, FACSM)
Email: sfelton@fgcu.edu

(No relevant relationships reported)

Injuries of the ulnar collateral ligament (UCL) are a common pathology and have been well documented for overhead athletes. However, little research has focused on the UCL in competitive golfers, though medial elbow injuries are commonly reported. Ultrasound imaging is becoming a common diagnostic tool to diagnose UCL pathology. In addition, USI protocols have been able to reliably identify the width of the UCL at the mid substance and apex of the trochlea. **PURPOSE:** The purpose of this pilot study was to examine if differences in UCL width at the mid substance and apex of trochlea existed between the trailing and lead arm of asymptomatic golfers.

METHODS: Seven asymptomatic NCAA Division I collegiate female golfers (age 19.4 ± 1.4 yrs) participated in this study. Ultrasound images were obtained of the UCL on the participant's trailing and lead arms using a GE LOGIQ e ultrasound unit. Participants were placed supine with elbow position at 30 degrees, with a wedge placed underneath the humerus creating a gravity induced valgus force on the UCL. Ultrasound imaging measurements to evaluate the UCL at two points were performed from the apex of the trochlea to the apex of the ulna. A paired t-test was performed to evaluate differences in UCL width measurements.

RESULTS: The mean width of the UCL at mid-substance was .297cm (SD .047) in the trailing arm (mean width .297cm, SD .047) and .234cm (SD .033) in the lead arm. The mean width at the apex of the trochlea was .129cm (SD .022) and .114cm (SD .016), respectively. There was a significant difference between the UCL measurements at the mid-substance between the leading and the trailing arm (mean difference .062 cm, $t = 5.680$, $p = .036$), but the difference at the trochlea was not statistically significant.

CONCLUSIONS: The results of this pilot study indicate that the trailing arm's UCL has a larger width when comparing trailing arm with leading arm, potentially due to the increased valgus forces on the trailing elbow versus the leading elbow. These changes may be associated with structural adaptations or pathologies related to this increased load. However, it was beyond the scope of this study to identify the potential sources of the differences in width of the UCL at the mid-substance. Further research is thus recommended using larger sample size, extended study period and symptomatic populations.

Musculoskeletal Injuries In Charity Team Marathoners Training For The Boston Marathon

Rebecca G. Breslow¹, Angela T. Chen², Swastina Shrestha¹, Jeffrey N. Katz¹, Jamie E. Collins¹. ¹Brigham and Women's Hospital, Boston, MA. ²University of Pennsylvania, Philadelphia, PA. (Sponsor: Dr. Cheri Blauwert, FACSM)
Email: rbreslow@bwh.harvard.edu

(No relevant relationships reported)

Purpose: There is a gap in the sports medicine literature about injury types and rates in runners training for a marathon with a charity team. Our objectives were to: 1. Determine the types of injuries among members of a charity marathon team, and 2. Estimate the rates of injuries in this group.

Methods: This is a survey study with a secondary medical record review of the 2019 Stepping Strong charity marathon team at Brigham and Women's Hospital, Boston, MA (140 runners). Measures were: 1. Self-report baseline questionnaire, and 2. Symptom and function inventory questionnaires completed during the training cycle and after the Boston Marathon. We generated descriptive statistics and determined injury types and rates from these measures.

Results: Participants had a mean of 10.2 (SD 8.8) years of running experience, and most commonly averaged 10 to 19.9 miles per week (41.8%). The mean number of previous marathons trained for and completed was 5 (SD 10.3), and 94.9% raised \$7,500.00 or more. 26.3% of runners reported a medical-provider diagnosed injury, 43.8% reported an injury not diagnosed by a medical provider lasting more than 1 week, 40% reported pain due to running lasting more than 1 week, and 53.8% reported pain due to running of any duration. Injury locations are displayed in **Figure 1**. More than 50% of runners reported pain that interfered with their ability to run their usual distance at their usual pace, and approximately 25% of runners reported pain that interfered with their ability to walk. 76% of respondents to the post-race questionnaire reported they developed pain at some point during the marathon training cycle, and 88% of respondents indicated they would run a marathon again.

Conclusions: Less stringent injury definitions resulted in greater percentages of participants reporting injuries. The knee, foot and hip were common injury sites. Though most participants developed pain during the marathon training cycle, almost all indicated they would run a marathon again.

2864 Board #325 May 29 9:30 AM - 11:00 AM
Sex Differences In Quadriceps Strength And Rate Of Torque Development 6 Months Post ACL Reconstruction

Victor Huynh, Joshua J. Van Wyngaarden, Kathryn Lucas, Darren Johnson, Mary L. Ireland, FACSM, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.*

(No relevant relationships reported)

Quadriceps weakness is ubiquitous post anterior cruciate ligament reconstruction (ACLR) and is strongly associated with adverse long-term patient outcomes. To date, research is equivocal in healthy subjects that males are stronger than females. However, there has been little work defining sex differences in quadriceps strength post ACLR. Identifying sex differences in quadriceps strength may allow for targeted rehabilitation strategies.

PURPOSE: To determine whether sex differences in quadriceps strength and rate of torque development (RTD) exist in subjects 6 months after ACLR.

METHODS: Seventy-five subjects (43 M, age 19.5 ± 6.0 , Tegner 8.2 ± 1.7) 6 months after an ACLR performed maximum voluntary isometric contractions (MVIC) of the quadriceps. Subjects were positioned on a Biodex System 4 per previously reported literature. The average of four MVIC trials were normalized to the subjects' body weight. Sex differences in quadriceps strength and RTD in injured and uninjured limbs were compared using analysis of covariance, controlling for age.

RESULTS: The males were older ($M = 22.6 \pm 6.7$ years, $F = 16.8 \pm 3.4$ years, $p < 0.01$) and heavier ($M = 79.1 \pm 12.5$ Kg, $F = 66.4 \pm 18.6$ Kg, $p < 0.01$) than females. Despite controlling for age and body weight, males displayed higher peak quadriceps strength in the injured limb ($M = 2.1 \pm 0.6$ Nm/Kg, $F = 1.7 \pm 0.6$ Nm/Kg, $p = 0.02$, Cohen's $d = 0.63$) and uninjured limb ($M = 3.2 \pm 0.8$ Nm/kg, $F = 2.6 \pm 0.6$ Nm/kg, $p \leq 0.01$, Cohen's $d = 0.76$). There were no significant sex differences in the injured limb's RTD ($M = 5.5 \pm 2.1$ Nm/Kg, $F = 5.0 \pm 2.4$ Nm/Kg, $p = 0.65$, Cohen's $d = 0.22$) but males displayed higher RTD in the uninjured limb ($M = 10.4 \pm 3.8$ Nm/Kg, $F = 8.1 \pm 3.5$ Nm/Kg, $p = 0.025$, Cohen's $d = 0.59$).

CONCLUSION: Six months post ACLR, males had greater peak quadriceps strength bilaterally and increased RTD in the uninjured limb compared to females with moderate to large effect sizes. However, there was no significant sex difference in RTD on the injured limb. These data suggest that females may need continued progressive resistance strength training while males may be ready to progress power-based quadriceps training strategies 6 months post ACLR. Addressing the disparity in recovery of muscle strength may reduce long-term impairments associated with osteoarthritis and subsequent ACL injury risk.

Ultrasound Imaging To Assess Medial Elbow Joint Space In Female Collegiate Division I Golfers

Jacqueline van Duijn¹, Arie J. van Duijn², Shawn Felton², Mitchell L. Cordova, FACSM². ¹Florida Gulf Coast University, Fort Myers, FL. ²Florida Gulf Coast University, Fort Myers, FL. (Sponsor: Mitchell L. Cordova, FACSM)
 Email: jvanduij@fgcu.edu

(No relevant relationships reported)

Medial elbow complex injuries have been reported in competitive and recreational golfers. Ultrasound imaging (USI) is a common method for assessing medial joint stability in baseball and other overhead athletes, however there is a paucity of literature in golfers. During the golf swing, there are increased valgus forces on the trailing arm elbow versus the leading elbow, potentially leading to increased medial joint laxity of the trailing arm.

PURPOSE:

The purpose of this pilot study was to examine differences in medial elbow joint space (MJS) measured by USI between the trailing and lead arm of asymptomatic female collegiate golfers.

METHODS: Seven asymptomatic NCAA Division I collegiate female golfers (age 19.4 ± 1.4 yrs) participated. Ultrasound images of the medial joint space of both arms were obtained using a GE LOGIQ E ultrasound unit. Participants were placed supine with elbow position at 30 degrees, with a wedge placed underneath the humerus creating a gravity induced valgus force on the MJS. Measurements of the MJS were performed, and differences between the trailing and leading arm were analyzed with a paired t-test.

RESULTS:

Mean elbow MJS opening on the trailing arm was .32cm (SD.079cm), and .28cm (SD .096cm) on the leading arm. There was a statistically significant difference ($t = 3.495$, $p = .01$) between MJS opening measurements of the trailing and leading arms.

CONCLUSIONS:

The results of this investigation indicate that there is increased elbow MJS opening of the trailing arm compared to the leading arm. While this study does not allow for cause and effect conclusions, this is consistent with the increased load placed on the trailing arm MJS during the golf swing. Further research is needed using larger sample sizes, more heterogeneous study populations, and examination of injury rates and MJS measurements.

Loss Of Glenohumeral Range Of Motion And Its Effects On Eccentric Strength In Intercollegiate Pitchers

Charles E. Leddon¹, Rod A. Harter, FACSM². ¹Cincinnati Reds Major League Baseball Team, Cincinnati, OH. ²Texas State University, San Marcos, TX.

Email: CLeddon@reds.com

(No relevant relationships reported)

Deficits in glenohumeral joint rotational range of motion (ROM) and strength in baseball pitchers' shoulders have been linked to increased risk of musculoskeletal injury. Total arc of motion deficit (TAMD) is an objective parameter that involves the comparison of bilateral shoulder internal rotation (IR) and external rotation (ER) ROM values as a measure of soft tissue changes at that joint. **PURPOSE:** To determine whether TAMD in the throwing shoulder, when compared to the non-throwing shoulder, affected the eccentric strength of IR and ER muscles of the glenohumeral (GH) joints of intercollegiate baseball pitchers. **METHODS:** 47 male pitchers (age, 19.8 ± 1.2 yrs; hgt, 183.9 ± 5.5 cm; mass, 85.7 ± 10.2 kg; pitching experience, 9.9 ± 2.8 yrs) were recruited to this study and assigned to 1 of 2 groups: 24 pitchers with $\geq 10^\circ$ side-to-side differences in total rotational motion were assigned to the TAMD group, while 23 pitchers with less than 10° side-to-side ROM differences qualified for a non-deficit group (Non-TAMD). We measured eccentric IR and ER peak torques at 300%/sec bilaterally with an isokinetic dynamometer. **RESULTS:** We observed higher ER/IR strength ratios of the dominant arms when compared to the non-dominant arms of pitchers in both the TAMD ($85.2\% \pm 24.3\%$ and $45.4\% \pm 7.3\%$) and non-TAMD groups ($87.3\% \pm 22.8\%$ and $48.5\% \pm 8.1\%$) ($p < 0.001$). There were no significant differences between the normalized TAMD and non-TAMD dominant arm eccentric IR torques (0.497 ± 0.073 Nm/kg BW vs. 0.478 ± 0.062 Nm/kg BW) or eccentric ER torques (0.407 ± 0.082 Nm/kg BW vs. 0.411 ± 0.077 Nm/kg BW) ($p > 0.05$). Dominant arm eccentric ER/IR strength ratio ($86.2\% \pm 23.3\%$ vs. $47.0\% \pm 7.8\%$) and ER eccentric peak torque (0.410 ± 0.088 Nm/kg BW vs. 0.295 ± 0.049 Nm/kg BW) were both significantly greater than in the non-dominant arm ($p < 0.05$). Internal rotation eccentric peak torque (0.488 ± 0.088 Nm/kg BW vs. 0.636 ± 0.101 Nm/kg BW) was significantly higher in the non-dominant arm ($p < 0.05$). **CONCLUSIONS:** We found ER/IR ratios that were significantly higher in the dominant arms, but no significant differences in ER or IR eccentric strength between the TAMD and Non-TAMD groups. Loss of shoulder rotation ROM did not have a significant effect on the production of IR and ER eccentric torques at the GH joint in this sample of intercollegiate pitchers.

2867 Board #328 May 29 9:30 AM - 11:00 AM

Hamstring To Quadriceps Ratio After ACL Reconstruction In Males And Females

Mandeep Kaur, Joseph Hart, FACSM. *University of Virginia, Charlottesville, VA.* (Sponsor: Joseph M Hart, FACSM)
 Email: mandy6dhillon@gmail.com

(No relevant relationships reported)

PURPOSE: Restoring thigh muscle strength is a universal rehabilitation goal after ACL reconstruction (ACLR). The hamstring to quadriceps (H/Q) ratio has been used both clinically and in the laboratory as an important metric to detect knee strength imbalances. Previous research has identified sex differences in H/Q ratio among young healthy male and female athletes where males exhibit H/Q ratio around 48% and females around 55% at 180°/sec. The purpose was to compare interlimb H/Q

ratio in participants with ACL reconstruction (ACLR) and to explore the influence of participants sex. **METHODS:** Participants with primary, unilateral ACLR were included in the study. Participants with reinjury or revision surgery or bilateral injury were excluded. Data from 318 (155 males, 163 females) participants was recorded (22.4±9.2yr, 1.72±9.8 m, 75.8±18.1 kg, 8.9±7.8 months post-ACLR). We measured isokinetic peak torque at 90°/sec and 180°/sec for the quadriceps and hamstring muscles bilaterally. H/Q ratio was calculated from peak torque. Repeated measures AVOVA was used to compare H/Q between limbs (within-subject) and between sexes (side*sex interaction). **RESULTS:** We observed a significant main effect for side at 90°/sec (P<0.001) and 180°/sec (P<0.001) indicating the differences among ACLR side and contralateral side (Table 1) such that ACLR side had higher H/Q ratio compared to the contralateral side with medium effect size. Statistically significant differences in H/Q ratio were found among males and females such that females had higher ratio than males at 180°. No significant side*sex effects were found at 90°/sec (P=0.226) and 180°/sec (P=0.383). **CONCLUSION:** Sex differences in H/Q ratio in the current study are similar to prior reports. We observed higher H/Q ratio on the ACLR sides compared to the contralateral sides at both velocities. Differences in the H/Q ratio persist among ACLR side and the contralateral side following ACLR and this finding is not influenced by sex.

Table 1 Within and between subject differences

Variable	Mean (Std. Deviation)	Isokinetic Speed (deg/sec)	P value	Mean difference 95% confidence intervals, Effect size
Side	H/Q Ratio ACLR side	58.27 (15.66)	<0.001	15.09 (13.41 to 16.76)
	H/Q Ratio contralateral side	43.15 (7.38)		d=0.7
	H/Q Ratio ACLR side	55.72 (14.32)	<0.001	12.48 (10.92 to 14.04)
	H/Q Ratio contralateral side	43.22 (9.40)		d=0.5
Sex	Male	49.69 (13.4)	0.06	1.98 (-4.09 to 0.12)
	Female	51.68 (15.3)		d=0.06
	Male	48.02 (12.7)	0.01	2.28 (-4.98 to 0.67)
	Female	50.85 (14.2)		d=0.10

2868 Board #329 May 29 9:30 AM - 11:00 AM
The Quantity Of Rehabilitation Is Associated With Patient Reported Outcomes Following ACL Reconstruction

Chelsey Roe, Cale Jacobs, Darren Johnson, Brian Noehren, FACSM. *University of Kentucky, Lexington, KY.* (Sponsor: Brian Noehren, FACSM)
(No relevant relationships reported)

Athletes demonstrate impaired self-reported outcomes and reduced psychological readiness to return to sport (RTS) following anterior cruciate ligament reconstruction (ACLR). Formal physical therapy (PT), in conjunction with their home exercise program (HEP), ideally continues until an athlete is cleared to RTS. The quantity of total rehabilitation completed and its relationship to patient reported outcomes (PROs) remains unknown.

Purpose: Determine the relationship between the amount of rehabilitation from 4-6 months post-ACLR to PROs at 9 months.

Methods: Fifteen athletes (8 M, 16.7 ± 2.9 yrs., 171.2 ± 8.4 cm, 63.9 ± 13.3 kgs) completed a weekly four-question survey between 4-6 months following an ACLR. Questions consisted of the number of times the athlete went to PT, completed their HEP, ran, and lifted leg weights with activity ranging from 0-7 days/week. The survey was sent via a secure web-based database. At the 9-month follow-up, the athletes completed both the International Knee Documentation Committee (IKDC) and the ACL-Return to Sport after Injury (ACL-RSI). Pearson correlations were calculated between activity quantity from 4-6 months and PROs at 9 months.

Results: The average bouts of running per week (2.1 ± 1.5 bouts) 4-6 months after surgery was significantly associated with the 9-month IKDC (72 ± 6.9, r = 0.74, p < 0.01). Bouts of running per week (r = 0.54, p = 0.04) and increased adherence to the

HEP (3.5 ± 1.7 bouts, r = 0.56, p = 0.03) were significantly related to the 9-month ACL-RSI (55 ± 26). The average number of PT visits per week (0.96 ± 0.7) was not related to IKDC or ACL-RSI (p > 0.05).

Conclusion: These data suggest that increased activity, including running and HEP, during the critical 4-6-month period after surgery may result in increased self-reported outcomes and psychological readiness to RTS. Increased activity may improve athletes' comfort and confidence in their knee function. Those who were committed to running and their home exercises early after recovery may have continued to maintain this regimen through to their 9-month time point and thus felt better about their outcome. These data highlight the importance of athlete adherence to an early and consistent rehabilitation program, paired with clinician reinforcement of the HEP, for improved patient outcomes following ACLR.

Ultrasonography Of Femoral Acetabular Translation In Female Athletes Undergoing Hip Arthroscopy

Jacob Jones¹, Dai Sugimoto¹, Gregory Kobelski¹, Yi-Meng Yen¹, Young-Jo Kim¹, Thomas Wuerz², Travis Matheny¹, Eduardo Novais¹, Mininder Kocher¹, Pierre d'Hemecourt¹, Andrea Straccioli¹, FACSM¹. *¹Boston Children's Hospital, Boston, MA. ²New England Baptist Hospital, Boston, MA.* (Sponsor: Andrea Straccioli, FACSM)
 Email: jones.jacobc@gmail.com
(No relevant relationships reported)

BACKGROUND: Hip arthroscopy may be a risk factor for post-surgical microinstability, leading to ongoing pain. Dynamic hip ultrasonography (US) has shown to reliably measure femoral acetabular translation. Evidence regarding the effect of hip arthroscopy on femoral acetabular translation and subsequent stability is lacking, especially in female athletes. **PURPOSE 1.** To examine ultrasound measurements of femoral acetabular translation in female athletes. 2. To compare dynamic US measurements in female athletes who have undergone hip arthroscopy versus female athletes who have not. **METHODS:** Cross-sectional study design. Dynamic US examination of femoroacetabular joint translation was performed in three positions: neutral hip, neutral hip with contralateral hip in flexion, and apprehension position (extension external rotation) (d'Hemecourt et al, *CORR*, 2018). Variables include age, sex, BMI, Beighton score, acetabular coverage angles. **Main outcome measure** US measures (mm) of femoral acetabular translation. Multivariate analysis of covariance (MANCOVA) with p < 0.05 was used for statistical analysis. Independent variable hip arthroscopy vs. no hip arthroscopy. Covariates include Beighton scores and acetabular angles. **RESULTS:** 171 female athletes were included. Twenty-five female athletes underwent right hip arthroscopy, and 17 left hip arthroscopy. In the neutral position, mean femoral acetabular translation in arthroscopy patients was 2.11±2.10 mm compared to non-arthroscopy study athletes (1.76±1.99 mm; p=0.349). In the neutral with hip flexion position, translation of arthroscopy study athletes was greater when compared to translation in non-surgical study athletes (5.17±2.00 mm and 4.38±2.49 mm, respectively), with a trend toward significance (p=0.088). Arthroscopy female athletes showed greater translation in the apprehension position compared to non-surgical female athletes (6.33±2.37 mm, 5.39±2.37 mm, respectively; p=0.042). **CONCLUSION:** Female athletes undergoing hip arthroscopy demonstrated differences in femoral acetabular translation via dynamic US when compared to female non-surgical patients while accounting for acetabular coverage and ligamentous laxity. Continued investigation of hip stability using dynamic US and future clinical utility is warranted.

The Effect Of Plyometric Training With Blood Flow Restriction After Anterior Cruciate Ligament Reconstruction

Serdar Demirci¹, Fatma Bilge Ergen², Turhan Egemen², Volga Bayrakçı Tunay². *¹Balikesir University, Balikesir, Turkey. ²Hacettepe University, Ankara, Turkey.*
 Email: ptserdardemirci@gmail.com
(No relevant relationships reported)

Quadriceps and hamstring muscles weakness are common after anterior cruciate ligament reconstruction (ACLR). Despite rehabilitation programs, the problem persists and has negative effects on knee function. Plyometric exercises are used during rehabilitation to facilitate muscle strength, function and return to sports. However, the effects of plyometric training with blood flow restriction (BFR) have never been investigated on patients with ACLR.

PURPOSE: The aim of this study was to investigate the effects of plyometric training with BFR on muscle strength, muscle thickness and knee function after ACLR.

METHODS: Twenty-eight patients who completed a 12-week rehabilitation program after ACLR were included in the study. Patients were randomly allocated into two groups. Group-1 (n=14, age: 19.6±2.1 years) performed plyometric training with BFR 3 days a week for 8 weeks. Group-2 (n=14, age: 20.3±3.3 years) performed the same

plyometric training without BFR. Knee muscle strength, muscle thickness and knee function were evaluated before and after the interventions. Concentric knee extension and flexion muscle strength were evaluated with isokinetic dynamometer at 60°/s and 180°/s angular velocities. The thickness of the rectus femoris (RF), vastus medialis obliquus and lateralis (VMO-VL) were assessed with ultrasonography. Vertical jump (VJ) and one-leg hop (OLH) tests were used to assess the performance of the patients. The subjective knee function was evaluated with IKDC knee form and ACL-RSI score. In addition one leg hop test and ACL-RSI score were evaluated only after intervention. Mann Whitney-U test was used to analyze the change before and after the intervention between groups.

RESULTS: Group-1 had significantly higher quadriceps ($p<0.05$, $p<0.05$) hamstring muscle strength ($p<0.05$, $p<0.05$) at 60°/s and 180°/s angular velocities respectively and higher muscle thickness of RF ($p<0.05$), VL ($p<0.05$) and VMO ($p<0.05$) compared to group-2. In addition, the VJ test ($p<0.05$) and ACL-RSI score ($p<0.05$) were higher in group-1 compared to group-2.

CONCLUSIONS: The results of the study indicated that plyometric training with BFR was more effective in improving the muscle thickness, muscle strength and knee function.

Comparison Of The Prevalence Of Hypertension Using Fourth Report And The Aap Guidelines Among Nigerian Children And Adolescent

Sunday Olawale Onagbiye¹, Abel Lamina Toriola². ¹University of the Western Cape, Cape Town, South Africa. ²Tshwane University of Technology, Pretoria, South Africa.
Email: onagbiyesunday@gmail.com
(No relevant relationships reported)

BACKGROUND: This study compared the prevalence of hypertension based on the Fourth Report guidelines issued in 2004 (old) and the recent (new) 2017 American Academy of Pediatrics (AAP) clinical practice recommendation for describing hypertension among Nigerian children and adolescents.

METHODS: Descriptive cross-sectional study of 1758 (boys= 631; 35.9% and girls=1127; 64.1%) aged between 9 and 19 years in Ado-Ekiti, Southwest Nigeria participated in the study. Stature, body mass, abdominal obesity, systolic and diastolic blood pressure (BP) were determined using the standard protocols of ISAK, and BPs for all school-going children at each screen were classified by both fourth report guidelines (FRGs) and AAP guidelines.

RESULTS: Mean body mass, waist-to-hip ratio (WHR) ($p\leq 0.05$), body mass index (BMI) ($p<0.01$), body fat percentage and both systolic and diastolic blood pressure were significantly higher among boys compared to girls ($p < 0.001$). Based on the new guideline (AAP), the prevalence of hypertension by gender systolically, stands at 9.5% and 5.9% compared to the 4th report guidelines of 1.5% and 1.7% for boys and girls, respectively, and diastolically stands at 6.3% and 3.9% compared to the 1.6% and 0.9% for boys and girls, respectively. Based on AAP and by age, 12.1% and 12.8% of children aged 15 and 16 years were systolically and diastolically hypertensive, respectively. The result of the hypertension prevalence based on the 4th report criteria by age revealed that 5.8% and 2.8% of those aged 15 and 14 years were systolically and diastolically hypertensive, respectively.

CONCLUSIONS: A strikingly high prevalence of hypertension was found in children and adolescents following the recent AAP guidelines compared to the Fourth Report guidelines highlighting the need to scale up the intervention and prevention in children especially from low-income countries.

Boxing Training Effects On Brachial And Popliteal Endothelial Function In Prehypertensive Individuals

Paulina Caraveo, Francisco M. Acuna, Andrea Rico, Carlos Rehbein, Manuel Gomez, Lisa Rodriguez, Alvaro N. Gurovich, FACS. *The University of Texas at El Paso, El Paso, TX.*
(Sponsor: Alvaro N Gurovich, FACS)
Email: pcaraveo@miners.utep.edu
(No relevant relationships reported)

PURPOSE:

Endothelial dysfunction appears to have a central role in the progression to high blood pressure by reducing nitric oxide bioavailability and increasing oxidant stress. Flow mediated dilation (FMD) is the most common non-invasive test to assess endothelial function. It has been reported that traditional lower-extremity exercise modalities are associated with improvements on FMD, however, limited research has evaluated the effects of upper body exercise, such as boxing training, on endothelial function. Therefore, the purpose of this study is to determine the response of brachial and popliteal FMD within a prehypertensive population after 6 weeks of boxing training.

METHODS:

A total of 14 prehypertensive participants were randomly allocated to a boxing intervention or a control group. The boxing training intervention consisted of a 6-week program with 3 visits per week in non-consecutive days. Each session was made up of 10 rounds of 3 minutes and 1-minute rest in between rounds. The control group included a 6-week flexibility and balance training with 3 visits per week made up of 10 minutes of dynamic stretching, 5 minutes of unipedal stance, and 5 minutes of upper limb stretching. FMD of the brachial and popliteal artery were measured with a 12-MHz linear phase array ultrasound transducer before and after the intervention.

RESULTS: After the intervention, the boxing group showed a significant increment on brachial FMD by 2.4% ($p = 0.001$) and popliteal FMD by 2.8% ($p = 0.043$), while no statistical differences were found in the control group for brachial FMD ($p = 0.181$) and popliteal FMD ($p = 0.538$).

CONCLUSION: Boxing training is a suitable exercise alternative to improve endothelial function in the upper and lower extremity of individuals with prehypertension.

2874 Board #335 May 29 10:30 AM - 12:00 PM

Effects Of Boxing Training On Peripheral And Central Blood Pressure And Arterial Stiffness In Prehypertension

Francisco Morales-Acuna, Manuel Gomez, Lisa Rodriguez, Alvaro Gurovich, FACS. *The University of Texas at El Paso, El Paso, TX.* (Sponsor: Alvaro Gurovich, FACS)
Email: fmoralesac@miners.utep.edu
(No relevant relationships reported)

PURPOSE: Early stages of high blood pressure, such as elevated blood pressure or stage 1 hypertension, have shown to increase cardiovascular mortality. Exercise is recommended for the prevention and treatment of high blood pressure; however, most clinical evidence is based on lower-body modalities of exercise. Therefore, the purpose of this study is to evaluate the effects of boxing training, a predominant upper-body exercise modality, on peripheral and central blood pressure and arterial stiffness in prehypertensive individuals. **METHODS:** A total of 14 young prehypertensive individuals were randomly allocated to a boxing training group or to a control group for 6 weeks. The boxing group underwent 42 minutes of boxing training three times per week while the control group performed flexibility and balance exercises. At the beginning and at the end of the intervention, brachial blood pressure was evaluated with an automatic cuff, central blood pressure by pulse wave analysis, and arterial stiffness by pulse wave velocity. A 2x2 repeated measures ANOVA design was employed to compare differences within and in between groups. Significance was established at $p \leq 0.05$. **RESULTS:** After the intervention, only the boxing group showed a significant reduction on systolic blood pressure ($p=0.027$), diastolic blood pressure ($p<0.001$), central systolic blood pressure ($p=0.011$), augmentation index ($p=0.021$), and augmentation index at 75 beats per minute ($p=0.008$). No difference could be observed on pulse wave velocity in the boxing group ($p=0.323$), although a significant increment was seen in the control group ($p=0.02$). **CONCLUSIONS:** Boxing training is an effective treatment alternative to reduce peripheral and central blood pressure in prehypertensive individuals. To reduce arterial stiffness in prehypertensive individuals, longer boxing training protocols might be required.

2875 Board #336 May 29 10:30 AM - 12:00 PM

Dexa Body Composition And Cardiovascular Risk Markers Are Weakly Related In Male Firefighters With Fatty Livers

Steven E. Martin, Sean Stanelle, Jason R. Lytle, Alexandra Remy, Carina Peltier, John S. Green, FACSM, Stephen F. Crouse, FACSM. *Texas A&M University, College Station, TX.* (Sponsor: Stephen F. Crouse, FACSM) Email: semartin@tamu.edu
(No relevant relationships reported)

PURPOSE: To determine if obesity measures, such as fat mass and distribution (e.g. android, gynoid, and visceral fat levels), could be used to predict markers of cardiovascular disease (CVD), particularly lipoprotein-lipid levels among firefighters recently diagnosed with fatty livers (radiologist interpretation from ultrasound). **METHODS:** Thirty-three local male firefighters who had recently been diagnosed with a fatty liver and completed their annual cardiovascular health profile screenings were included in this data analysis (average age 39.5±8.6 yrs, height 70.9±3.1 in, weight 242±42.6 lbs, fat mass 76.14±24.5 lbs; lean mass 162.5±21.7 lbs; percent android fat 38±5.3; percent gynoid fat 29.4±4.7; visceral fat area (VAT) 170.5±47.3 cm², and VO_{2max} 30.0±5.0 mL/kg/min). Data taken from their annual health screening included a graded exercise test (GXT; Bruce protocol), body composition (through DEXA), and fasting bloodwork. Maximal oxygen uptake (VO_{2max}) was estimated using the Foster equation. Height, weight, resting heart rate, resting systolic blood pressure, and resting diastolic blood pressure were measured before the start of the GXT protocol. All blood samples were analyzed for total cholesterol (TC), triglycerides (TG), high-density lipoprotein (HDL) cholesterol (HDL-C), low-density lipoprotein (LDL) cholesterol (LDL-C), and glucose (GLU). Relationships among the data were analyzed with Pearson's r (Significance was determined using an alpha level of 0.05). **RESULTS:** Correlations for obesity measures and other cardiovascular risk markers of interest are displayed in Table 1 (* = p < 0.05).

		Lean Tissue Mass	Fat Tissue Mass	Android Fat %	Gynoid Fat %	VAT
TC	Pearson	-.110	.059	.119	.216	-.253
	r ²	.012	.003	.014	.047	.064
HDL-C	Pearson	-.290	.155	.353*	.414*	-.312
	r ²	.084	.024	.125	.171	.097
LDL-C	Pearson	-.099	.011	.041	.140	-.393*
	r ²	.009	.000	.002	.019	.154
TG	Pearson	.058	-.019	-.020	-.079	.313
	r ²	.003	.000	.000	.006	.098
Glucose	Pearson	.127	-.038	.053	.024	-.235
	r ²	.016	.001	.003	.001	.055
VO _{2max}	Pearson	-.381*	-.637*	-.603*	-.476*	-.285
	r ²	.145	.406	.363	.226	.081

CONCLUSIONS: VO_{2max} was significantly, but weakly related to lean mass, fat mass, and the percentage of both android and gynoid fat. Factors other than fat mass and distribution may contribute to lipid profiles in our male firefighters with fatty livers, a population at high risk for CVD.

2876 Board #337 May 29 10:30 AM - 12:00 PM

Heart Rate Variability On Older Adults With Intellectual Disability: A Cross-sectional Study

Ana Claudia Silva Farche¹, Manel Font Farré², Anielle Cristhine de Medeiros Takahashi¹, Casimiro Javierre³, Míriam Guerra-Balic², Guillermo Rúben Oviedo². ¹Universidade Federal de São Carlos, São Carlos, Brazil. ²Universitat Ramon Llull, Barcelona, Spain. ³Universitat de Barcelona, Barcelona, Spain. Email: anaclaudiafarche@gmail.com
(No relevant relationships reported)

PURPOSE: There is a deficit on autonomic nervous system regulation in individuals with Down syndrome (DS). However, the cardiac autonomic modulation during exercise in older adults with intellectual disability (ID) without DS is not enough described. **AIM:** To evaluate and compare the heart rate variability (HRV) during the six-minutes walk test (6MWT) in older adults with and without ID. **METHODS:** Seventeen participants with low-moderate ID non DS and 25 participants without ID were recruited. The HRV was assessed by R-R intervals on rest (10 minutes before the test), during the 6MWT and on recovery (10 minutes after the test), in orthostatic position by a Polar RS800X heart rate monitor. The symbolic analysis was used to evaluate nonlinear HRV components, and 0V% and 2UV% variations were considered as sympathetic and vagal modulation parameters, respectively. Two-way Anova was used to compare HRV parameters between the groups on rest, 6MWT and recovery. **RESULTS:** Only the group without ID showed a significant increase of 0V% values (p=0.003), and a decreased 2UV% (p=0.003), as expected. Both groups showed a significant reduction in RRI mean (p=0.006). Distance walk on 6MWT was significant higher in the group without ID (536 m vs. 452 m (p=0.001) **CONCLUSION:** participants with ID did not present cardiac autonomic modulation responses during

the exercise, and show a worse performance in 6MWT. Thus, future studies are needed to elucidate the autonomic cardiac control during exercise in seniors with ID, and assist on prescription of appropriate intervention for this population. **Funding sources:** MINECO (DEP2017-86862-C2-1-R); Generalitat de Catalunya. Departament d'Empresa i Coneixement (2019 FI_B 00893); Ministerio de Ciencia e Tecnologia de Brasil (PDSE/CAPES 88881.189815/2018-01).

Table 1: Heart rate variability on older adults with and without ID

Variables	Adults without ID (n = 25)			Adults with ID (n = 17)			p
	Mean (SD)			Mean (SD)			
Linear Parameters	Rest	6MWT	Recovery	Rest	6MWT	Recovery	
Mean iRR (ms) *	824 (168)	755 (167)	842 (167)	849 (129)	570 (80)	790 (122)	.006
Variance (ms ²)	778 (852)	721 (890)	810 (872)	824 (849)	887 (794)	829 (737)	.052
Non-Linear Parameters							
0V% **	26 (16)	33 (16)	46 (14)	33 (11)	30 (15)	32 (11)	.003
2UV% **	22 (12)	17 (8)	8 (6)	13 (8)	20 (11)	14 (9)	.003

Note: values are means (Standard Deviation). Abbreviations: ID (intellectual disability); 6MWT (six-minutes walk test); iRR (R-R intervals). Statistically significant values are showed in bold (p ≤ .05). * Significant difference (p ≤ .05) between rest and 6MWT for all groups. ** Significant difference (p ≤ .05) between rest and 6MWT w/ID group.

Aerobic Capacity And Physical Activity Level In Adults With Congenital Heart Disease

Kelly dos Santos Ferri¹, Maite Doñate², Mireia Parra², Myriam Guerra-Balic¹, Guillermo Oviedo¹, Gloria Navarro³, Ricard Serra-Grima². ¹Ramón Llull University, Barcelona, Spain. ²Santa Creu i Sant Pau Hospital, Barcelona, Spain. ³Cors Units Foundation, Barcelona, Spain. Email: kellyprisciladfb@blanquerna.url.edu
(No relevant relationships reported)

PURPOSE: To study the Aerobic Capacity (AC) in adults with Congenital Heart Disease (CHD) and their physical activity (PA) level. **METHODS:** A cross sectional study with 93 adults (45 women 36,2±10,1 years; and 48 men 35,4±11,9 years) participated in the study. The AC was assessed by cardiopulmonary exercise test (CPET) using a modified Bruce protocol. Considering values of peak oxygen uptake (VO_{2Peak}), participants were divided into four Fitness levels (FL) quartiles (Very Low, Low, Moderate and high) for each sex. Three categories of PA level (Health-Enhancing Physical Active (HEPA), Minimally active and Inactive) were obtained by the short International Physical Activity Questionnaire (IPAQ) based on spending MET/minutes/week. Analysis of variance (ANOVA one way; post-hoc Bonferroni) to evaluate significant differences among FL and PA level were used. **RESULTS:** Significant differences appeared in VO_{2Peak} between all FL groups for both sexes. In women the VO_{2Peak} of the very low FL group was 18.5±2.8 ml/kg/min, Low FL 23.2±1.5, Moderate FL 27.6±2.2, and High FL 35.7±5.6 (P=0.001). In men the VO_{2Peak} of the very low FL group was 22.1±3.7 ml/kg/min, Low FL 30.1±3.6, Moderate FL 34.9±4.7 and High FL 47.8±6.7 (P=0.001). No significant differences were observed among FL groups in terms of PA with a mean of 2659.3±2210.0 MET/minutes/week. However, the high FL group showed an upward trend in spending MET/min/week compared with the others groups. Thirty-two participants (34.4%) reported HEPA, 49 (52.7%) reported minimally active and 12 (12.9%) reported inactivity. **CONCLUSION:** Aerobic Capacity in adults with CHD was low compared to regular values in healthy population. These findings suggesting that when the goal is to improve aerobic capacity and prognosis of disease should be recommended increase PA. Future studies with a larger sample size are needed to determine level of PA appropriate to improve aerobic capacity in adults with CHD. Supported by SUR of DEC Generalitat de Catalunya and European Union 2019FI_BI 00168.

Comparison Of Oxyhemoglobin, Deoxyhemoglobin, Tissue Oxygen Saturation, And Venous Occlusion Plethysmography

Manuel Gomez, Francisco Morales-Acuna, Alvaro N. Gurovich, FACSM. *University of Texas at El Paso, El Paso, TX.* (Sponsor: Alvaro N. Gurovich, FACSM)
 Email: mgomez26@miners.utep.edu
 (No relevant relationships reported)

Near infrared spectroscopy (NIRS) a non-invasive technique used to measure tissue perfusion and oxygenation. Recent studies used the combination of a Venous occlusion plethysmography (VOP) with NIRS to study microvascular function. NIRS have demonstrated to monitor effectively perfusion changes in muscle microcirculation. The purpose of this study was to determine if NIRS can predict microvascular blood flow measurement via VOP.

A total of 20 young apparent healthy subjects, were recruited for this study. NIRS and VOP were performed simultaneously at the right forearm and right calf. VOP strain gauges placed around the widest part of both extremities between cuffs. Probes for NIRS were placed on forearm and calf both perpendicular to the longitudinal axis. Baseline levels were obtained for a minute for NIRS and VOP. Followed by an ischemic stress were cuffs were inflated to a suprasystolic pressure for five minutes. Post ischemic stress data was collected for one minute. Strength association was evaluated by Pearson correlation.

Lower extremity demonstrated a positive correlation with average basal oxyhemoglobin (HbO₂) versus, slope of deoxyhemoglobin (HHb) (R= 0.541; P= 0.014). HHb 30 seconds before ischemic stress is release had a positive correlation with tissue oxygen saturation (SO₂) slope (R =0.873; P <0.05). HHb post ischemic stress slope had a positive correlation with HbO₂ slope (R = 0.665; P=0.001). Upper extremity, HbO₂ post ischemic stress versus HHb post ischemic stress showed a positive correlation. (R = 0.916; P = <0.05). HbO₂ 30 seconds before ischemic stress versus HHb 30 seconds before ischemic stress slope had a positive correlation (R = .784; P = <.05). No correlation was found with VOP measurements. There were no agreements between NIRS and VOP, for the assessment of microvascular function.

Effect Of Pulmonary Function On Metabolic Response To Exercise In Patients With Bicuspid Aortic Valve

Andrea Grzeszczak, Wayne A. Mays, Mallorie C. Rice, Sandy K. Knecht, Justine D. Shertzer, Samuel G. Wittekind, Adam W. Powell, Clifford Chin, Michael Khoury. *Cincinnati Childrens Hospital Medical Center, CINCINNATI, OH.*
 Email: grezak90@gmail.com
 (No relevant relationships reported)

PURPOSE: To evaluate the effect of resting pulmonary function on metabolic responses to exercise in patients with a bicuspid aortic valve (BAV) compared to normal control subjects (C). **METHODS:** We evaluated 18 BAV patients and 18 C subjects, age and size matched, using a Ramp Treadmill protocol. Pulmonary function was evaluated with resting spirometry measures of Forced Vital Capacity (FVC) and Forced Expiratory Capacity in the first second (FEV1). Breathing reserve was calculated (BR). Oxygen consumption, absolute (VO₂) and indexed (VO_{2i}), percent predicted VO₂ (%PVO₂), expiratory minute volume (VE) and respiratory exchange ratio (RER) were obtained at anaerobic threshold (AT) and maximal exercise (Max). **RESULTS:** There were no significant differences between the BAV and C groups in age (14.6 ± 2.1 vs 15.8 ± 3.1(yr)), height (1.63 ± 0.1 vs 1.66 ± 0.12(m)) or weight (55.7 ± 15.1 vs 57.6 ± 13.2 (kg)). The BAV group had significantly decreased FVC (3.54 ± 0.84 vs 4.16 ± 1.03(L/min) p<0.05) and FEV1 (3.54 ± 0.84 vs 4.16 ± 1.03(L/min) p<0.02) compared to the C group. BAV group had a significant decrease in VO₂ (1524 ± 466 vs 1876 ± 540 (ml/min) p<0.04), VO_{2i} (28 ± 8 vs 33 ± 5 (ml/min/kg) p<0.04) and VE (35 ± 11 vs 42 ± 10 (L/min) p<0.02) at AT but not at Max. The %PVO₂ was significantly decreased in the BAV group at AT (67 ± 19 vs 83 ± 18 (%) p<0.01) and Max (91 ± 24 vs 109 ± 17 (%) p<0.01). BR was significantly decreased in the BAV group (46 ± 6 vs 50 ± 6 (%) p<0.05) Max RER was not significantly different in BAV and C groups (1.19 ± 0.08 vs 1.19 ± 0.06). Significance was set at p < 0.05. **CONCLUSION:** BAV and C groups reached the same intensity of exercise reflected by the RER. BAV group had decreased pulmonary function, reflected by FVC and FEV1, with a decreased BR. BAV had decreased aerobic performance at AT and Max, reflected by the VO₂, VO_{2i}, and VE at AT and %PVO₂ at AT and Max. These data suggest that a significant pulmonary function component contributes to the decreased aerobic performance in these BAV patients.

High-intensity Interval Training And Resistance Training Favor Higher Improves On Cardio-metabolic Health Outcomes Compared With Combined Training Or Nutritional Guidance In Overweight Adults: Cardiometabolic Hiit-rt Study, A Randomized Controlled Trial

Robinson Ramirez-Vélez¹, Mikel Izquierdo¹, Jorge Enrique Correa-Bautista¹, Katherine González-Ruiz². ¹Public University of Navarra, Pamplona, Spain. ²Universidad Manuela Beltrán, Bogotá, Colombia.
 Email: robin640@hotmail.com
 (No relevant relationships reported)

PURPOSE: The 2018 Physical Activity Guidelines Advisory Committee systematically searched existing literature reviews to assess the relationship between high-intensity interval training (HIIT), moderate-intensity continuous training (MICT), or resistance training (RT) and reduction in cardiometabolic disease risk. Against this background, the aim of the present study was to investigate whether 12 weeks of HIIT, RT, combination training (CT = HIIT+RT) or a NG plan induced improvement on metabolic syndrome risk factors, vascular function and physical fitness in sedentary and overweight, and to compare the responses between the four intervention groups. **METHODS:** The study included a total of 57 sedentary subjects with abdominal obesity or excess weight. Twelve-week randomized parallel design examining the effects of different exercise regimes and/or NG on anthropometric and body composition (fat and lean mass at whole body, trunk fat, fat mass index, appendicular muscle mass, and waist circumference); metabolic syndrome risk factors and vascular parameters (blood lipids, fasting glucose, blood pressure, flow-mediated vasodilation [FMD%], aortic pulse wave velocity (PWV), and augmentation index [AIx]); and physical fitness (cardiorespiratory fitness and grip strength).

RESULTS: Adjusted mixed linear models revealed a significant improved in cardiorespiratory fitness (mL·kg⁻¹·min⁻¹): HIIT +8.3, RT +4.1, and CT +6.3 (all P < 0.001). The improvement difference between the groups was statistically significant between the HIIT and NG group (P = 0.014), [time x group interaction F_(23,564); P < 0.001; η² partial = 0.365]. In addition, RT and CT group, has a significant positive impact on PWV (m·s⁻¹) (d = 0.391 and 0.229 respectively; P < 0.001, [time x group interaction F_(5,457); P = 0.003; η² partial = 0.280]. Hereafter, RT group has a significant positive impact on the FMD (%) in comparison to HIIT, CT or NG group (time x group interaction F_(2,942); P = 0.044; η² partial = 0.174).

CONCLUSIONS: The main findings of this study are that 12 weeks of HIIT leads to significant improvements in cardiorespiratory fitness while the RT resulted in improvements in the vascular profile, supporting the positive effect of both training programs for cardiometabolic risk factors in sedentary and overweight adults.

Acute Cardiopulmonary And Hemodynamic Responses To Exercise With Blood-flow Restriction In Heart Failure Patients

Ioannis Aristoteli Kothonidis, Spyridoula Goutsou, Dimitrios Delis, Eleftherios Karatzanos, Serafim Nanas, Anastassios Philippou. *NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, Athens, Greece.*
 (No relevant relationships reported)

Muscle training with blood flow restriction (BFR) can induce significant increases in muscle strength and mass, while BFR during low intensity aerobic training increases aerobic capacity more than the usual aerobic exercise at the same intensity. However, little is known about the safety and feasibility of BFR training in patients with chronic heart failure (CHF).

PURPOSE: This study compared hemodynamic and cardiopulmonary responses during low intensity aerobic exercise with and without BFR in CHF patients. **METHODS:** Nine CHF patients, 7 males and 2 females (age: 55.6±12.2 years, height: 175.0±10.3 cm, body mass: 89.6±29.1 kg, VO_{2peak}: 22.4±5.04 ml/kg/min, ejection fraction: 36±6%, NYHA: I-II) volunteered to participate in this crossover study. Each participant performed the same aerobic exercise protocol, i.e. a 20-minute cycling bout at 65% of VO_{2peak}, with (BFR) and without BFR (control) in random order, using a cycle ergometer. In the BFR condition, an occlusion cuff was used to regulate the occlusion pressure applied to both limbs that was proportional to thigh circumference. Mean oxygen uptake (VO₂) during the 20 minutes exercise, VO₂ recovery during the first minute of recovery (VO₂/t slope), heart rate (HR), systolic (SBP) and diastolic (DBP) blood pressure at 6 min, 12 min and 18 min of exercise, fatigue and dyspnea perception were assessed. ANOVA or paired t-test was used for statistics and data are presented as mean±SD.

RESULTS: Mean VO₂ during exercise was higher in BFR compared to control (70.6±9.8% vs 64.0±10.1%, p=0.003), while VO₂/t slope was higher in control (0.79±0.23 vs 0.53±0.11, p= 0.008). HR was higher during the BFR exercise (94±15

vs 88 ± 15 , 97 ± 20 vs 90 ± 19 , 96 ± 10 vs 84 ± 9 at 6, 12 and 18 min, respectively; $p < 0.05$), whereas SBP and DBP did not differ between the two conditions at any time point ($p > 0.05$). Fatigue (12.4 ± 2.7 vs 8.8 ± 1.7 , $p = 0.002$) and dyspnea (11.5 ± 2.5 vs 9.2 ± 1.9 , $p = 0.03$) perception were significantly higher in BFR compared to control.

CONCLUSIONS: To our knowledge, this is the first study examined BFR exercise in CHF patients, revealing specific cardiopulmonary and hemodynamic responses and suggesting that this exercise strategy is safe and feasible in those patients. More studies are needed to verify and further characterize the acute and chronic effects of BFR training in CHF patients.

2882 Board #343 May 29 10:30 AM - 12:00 PM
Comparison And Correlation Between Cardiovascular Risk Factors And Skeletal Muscle Mass In Healthy Young Adults

Yeonhwi Kim, Minje Ji, Sewon Lee. *Incheon National University, Incheon, Korea, Republic of.*

Email: maxyh7@naver.com

(No relevant relationships reported)

It is unclear whether individuals with high skeletal muscle mass may have beneficial effects on cardiovascular health. **PURPOSE:** To ① Compare cardiovascular risk factors between individuals with Standard skeletal Muscle mass Group-Male (SMG-M) / Female (SMG-F), and High skeletal Muscle Group-Male (HMG-M) / Female (HMG-F) ② Explore the relationship skeletal muscle mass and cardiovascular risk factors.

METHODS: Fifty Healthy young male ($n=27$, 23.4 ± 0.4 years old) and female ($n=23$, 22.1 ± 0.4 years old) were recruited to participate in this study. Body composition of the subjects were measured by a Bioelectrical Impedance Analysis. Depending on the results, they were divided into 2 groups (HMG-M vs. SMG-M, HMG-F vs. SMG-F). Blood pressure, brachial-ankle pulse wave velocity (baPWV), and blood analysis [Low Density Lipoprotein Cholesterol (LDL-C), High Density Lipoprotein Cholesterol (HDL-C), Triglycerides (TRG), glucose, HbA1c] were performed.

RESULTS: There were statistically significant differences in the values of skeletal muscle mass Index (SMI) between the two groups [HMG-M vs. SMG-M, SMI(%) 130.5 ± 1.5 vs. 101.9 ± 1.3 , $p < 0.0001$; HMG-F vs. SMG-F, SMI(%) 109.0 ± 1.5 vs. 86.2 ± 2.3 , $p < 0.0001$]. Blood analysis showed that HDL-C was higher in HMG than in SMG [HMG-M vs. SMG-M, (mg/dL): 71.7 ± 4.7 vs 47.5 ± 2.3 , $p = 0.0001$; HMG-F vs. SMG-F: 79.0 ± 3.8 vs. 54 ± 2.3 , $p < 0.0001$], whereas LDL-C and TRG levels were comparable in the groups regardless of gender [HMG-M vs. SMG-M, LDL-C (mg/dL): 90.5 ± 12.1 vs 76.2 ± 12.4 , $p = 0.427$, TRG (mg/dL): 124.0 ± 22.5 vs. 104.5 ± 22.0 , $p = 0.549$; HMG-F vs. SMG-F, LDL-C: 97.2 ± 8.5 vs. 91.8 ± 6.6 , $p = 0.626$, TRG: 80.4 ± 15.0 vs. 96.0 ± 14.6 , $p = 0.477$]. In addition, baPWV did not show significant differences between groups [HMG-M vs. SMG-M, (cm/s): 1129.5 ± 18.2 vs. 1100.0 ± 49.8 , $p = 0.589$; HMG-F vs. SMG-F, 1001.7 ± 41.4 vs. 997.0 ± 73.2 , $p = 0.957$]. Interestingly, HDL cholesterol levels are associated with SMI in young adults (Male, $r = 0.640$, $p = 0.001$; Female, $r = 0.583$, $p < 0.01$).

CONCLUSIONS: In both male and female groups, HDL was significantly higher in HMG than in SMG, and a significant correlation was found between skeletal muscle mass index and HDL cholesterol. These results suggest that an increase in skeletal muscle mass may have an additive benefit on a cardiovascular risk factor, especially HDL cholesterol level.

2883 Board #344 May 29 10:30 AM - 12:00 PM
Acute Muscle Damage Is Augmented After Exercise In PAD Patients: Evidence From Diffusion Tensor Imaging

Jon Stavres¹, Jianli Wang², Christopher T. Sica², Cheryl Blaha¹, Michael Herr¹, Samuel Pai¹, Aimee Cauffman¹, Jeffrey Vesek², J. Carter Luck¹, Qing X. Yang², Lawrence I. Sinoway¹. ¹Penn State Heart and Vascular Institute, Hershey, PA. ²Pennsylvania State University, Hershey, PA.

(No relevant relationships reported)

Although the chronic myopathies associated with peripheral arterial disease (PAD) are well established, the acute muscular responses to exercise in this population are less clear. **PURPOSE:** This study used diffusion tensor imaging (DTI) to compare acute exercise related muscle damage between PAD patients and healthy controls. **METHODS:** Eight PAD patients and 7 healthy controls performed graded dynamic plantar flexion exercise in the bore of a 3T MRI scanner. In order to compare responses between the active and inactive legs, these plantar flexion trials were repeated during imaging of the exercising leg and imaging of the resting leg. Each exercise trial began at 2kg, and increased by 2kg every 2 minutes until fatigue, or until completion of 10kg. DTI images were collected from the widest portion of the calf pre and post exercise, and were analyzed for mean diffusivity (MD), fractional anisotropy (FA), and eigenvectors 1-3 ($\lambda_{1,2,3}$) of the medial gastrocnemius (MG) and tibialis anterior (TA) muscles. **RESULTS:** At baseline, there were no significant group differences in MD, FA, or any of the individual eigenvectors for the MG or TA of the exercising leg ($P \geq 0.34$). However, results did indicate significantly greater increases in MD ($+13.6$

$\pm 10.6\%$ and $+2.5 \pm 3.5\%$), λ_1 ($+13.7 \pm 14.3\%$ and $+1.4 \pm 3.1\%$), λ_2 ($+13.8 \pm 10.5\%$ and $+3.0 \pm 3.6\%$), and λ_3 ($+13.1 \pm 7.1\%$ and $+3.7 \pm 4.3\%$, all $P \leq 0.02$) in the MG of the exercising leg in PAD patients compared to controls, respectively. Results also indicated a significantly greater increase in λ_3 of the TA in the exercising leg in PAD patients compared to controls ($2.1 \pm 2.9\%$ and -1.5 ± 1.4 , respectively, $P = 0.01$). In contrast, no significant group by time interactions were observed in the resting leg (all $P \geq 0.15$). **CONCLUSIONS:** These data indicate that skeletal muscle diffusivity increases more in PAD patients compared to controls after exercise. Ultimately, this suggests that acute exercise related muscle damage is augmented in PAD patients. Supported by NIH P01-HL134609 (Sinoway) and UL1 TR002014 (Sinoway).

Examining Energy Expenditure During Aerobic And Resistance Exercise In Overweight Patients With HFpEF

Hannah Schultz, Peter Brubaker, FACSM, Tessa Roberts, Brittany Christensen, Dalane Kitzman. *Wake Forest University, Winston-Salem, NC.* (Sponsor: Peter Brubaker, FACSM)
 Email: schuhm18@wfu.edu

(No relevant relationships reported)

PURPOSE: Previous studies have demonstrated that aerobic exercise (AE) along with caloric restriction (CR) is very beneficial in older, overweight heart failure patients with preserved ejection fraction (HFpEF). However, few studies have evaluated the impact of resistance training (RT) in these patients. Consequently, little is known about energy expenditure (EE) associated with these types of exercises in overweight HFpEF patients, as well as the reproducibility of testing energy expenditure in this population. Therefore, the purpose of this study was to examine EE between overweight HFpEF patients participating in an AE alone versus AE+RT; and to examine the reproducibility of measuring EE in these patients.

METHODS: Nine overweight HFpEF participants of the *Studies Examining Caloric Restriction and Exercise Trial II (SECRET II)* participated in this study. All SECRET II participants were following a CR diet and were randomized into either an AE ($n=5$) or AE+RT ($n=4$) group. Each participant wore the COSMED K5 system during a single exercise session (~1 hr) in order to determine the total EE (kcal) for each session. Five of the nine subjects in (AE =2, AE+RT =3) wore the COSMED K5 during two different exercise sessions (within 1 week) to examine the reproducibility of EE measurement. An independent t-test was used to compare the mean total EE, during one exercise session, between the two groups. A Pearson correlation was run to examine the reproducibility in EE.

RESULTS: Despite similar exercise duration, the mean total EE during AE+RT (276 ± 182 kcal) not statistically different ($p = 0.53$) than during AE only (263 ± 125 kcal). A Pearson correlation revealed a significant correlation ($r = 0.95$, $p = 0.014$) between EE measured on day 1 and day 2. **CONCLUSIONS:** Data from this study indicates that AE+RT and AE alone results in similar EE and that this measure is reproducible in overweight patients with HFpEF. Thus, it appears that over time, AE and AE+RT would promote similar EE and potentially weight loss in overweight HFpEF patients.

2885 Board #346 May 29 10:30 AM - 12:00 PM
CARDIORESPIRATORY FITNESS AND VASCULAR HEMODYNAMICS IN MIDDLE-AGED AND OLDER ADULTS

Taylor C. Harman, Nicholas A. Carlini, Matthew P. Harber, FACSM, Leonard A. Kaminsky, FACSM, Michell H. Whaley, FACSM, Bradley S. Fleener. *Ball State University, Muncie, IN.* (Sponsor: Matthew Harber, FACSM)

(No relevant relationships reported)

Clinical Exercise Physiology, Ball State University, Muncie, IN, USA
 Cardiovascular disease-related (CVD) mortality with older age is in part attributable to altered vascular hemodynamics including increased central and peripheral blood pressure (BP) and augmentation index (AIx). Cardiorespiratory fitness (CRF) is inversely associated with CVD mortality independent of traditional risk factors. It is unknown, however, if CRF is inversely related to vascular hemodynamics. **PURPOSE:** To investigate the relationship between CRF and vascular hemodynamics in an apparently healthy middle-aged and older adult population. **METHODS:** Apparently healthy males and females ($N=101$; 54 M, 47 F; Age: 63.5 ± 8.5) from the Ball State Adult Fitness Longitudinal Lifestyle Study (BALL ST) were studied. All participants underwent assessment of vascular hemodynamics, which included non-invasive central and peripheral BP, central and peripheral pulse pressure (systolic minus diastolic BP), AIx (%), AIx normalized to HR 75 (AIx% HR75) and directly-measured CRF (VO_{2max} ; ml/kg/min). Age- and sex-adjusted CRF percentiles were calculated based on the Fitness Registry and Importance of Exercise National Database (FRIEND). Data were analyzed via Pearson correlations. **RESULTS:** CRF was inversely related with central systolic BP (cSBP, $r = -0.330$), central pulse pressure (cPP, $r = -0.255$), AIx % ($r = -0.366$), AIx% HR75 ($r = -0.474$), brachial systolic BP (bSBP, $r = -0.227$), and brachial pulse pressure (bPP, $r = -0.172$) (all, $p < 0.05$). cSBP ($r = -0.412$), cPP ($r =$

= -0.249), AIx % ($r = -0.202$), AIx % HR75 ($r = -0.292$), and bSBP ($r = -0.320$) were correlated with FRIEND percentiles (all, $p < 0.05$) whereas bPP ($r = -0.131$) was not ($p > 0.05$). **CONCLUSION:** Our findings demonstrate that more ideal measures of vascular hemodynamics are correlated with higher CRF in middle-age and older adults. These data support the notion that vascular hemodynamics may be a potential modulator in the inverse relationship between CRF and CVD in apparently healthy adults.

Associations Of Fitness, Physical Activity, And Fatness With A New Index Of Endothelial Function

Kerry J. Stewart, FACSM, Kellen A. Knowles, Pamela Ouyang, Elizabeth V. Ratchford, Laura Sullam, Harry A. Silber. *Johns Hopkins University, Baltimore, MD.*
 Email: kstewart@jhmi.edu

Reported Relationships: **K.J. Stewart:** Industry contracted research; *ordex, Inc.*

Current methods for assessing endothelial function, an early marker of cardiovascular disease (CVD), are either invasive or use noninvasive methods that are highly operator dependent or require nonreusable expensive probes, thereby limiting their use for CVD risk prediction. **Purpose:** To assess the relationship of fitness, physical activity (PA), and fatness, each a CVD risk factor, with a novel measure of endothelial function. **Methods:** This was a cross-sectional data analysis in adults recruited for a study examining the clinical utility of a new device that measures endothelial vasodilator function using a standard BP cuff. The resulting EnDys score is derived from direct calibrated measurements of brachial arterial compliance throughout the entire transmural pressure curve during a staged cuff release after 5 minutes of upper arm occlusion. A higher score means better endothelial function. Fitness was assessed by a 6-minute walk test (6MWT). Self-report of PA was assessed by the Rapid Assessment of Physical Activity tool. Body mass index (BMI) was used as a marker of general fitness and waist circumference (WC) as a marker of abdominal fatness. **Results:** In all 153 subjects, 51% were female, 7% were smokers, 7% had CVD, and 10% had type 2 diabetes. The mean \pm SD for age was 49.3 ± 17.2 , EnDys was 80.8 ± 30.4 , BMI was 29.3 ± 6.9 kg/m², WC was 37.5 ± 6.7 inches, and 6MWT was 495.4 ± 113.5 meters. EnDys was higher in females, 87.6 ± 30.5 , vs males, 73.8 ± 28.9 , $p < 0.01$. EnDys did not differ by being sedentary, 80.8 ± 27.6 , or active, 81.0 ± 33.0 , $p = 0.97$. Using bivariate analysis, a lower EnDys was associated with higher BMI, $r = -0.23$, higher WC, $r = -0.33$, lower 6MWT, $r = 0.32$, and older age, $r = -0.20$, all $p < 0.02$ or less. In a multivariate model, 6MWT ($\beta = -0.06$, $p < 0.01$), WC ($\beta = -1.02$, $p < 0.02$), and sex (female, $\beta = 6.9$, $p < 0.01$) were each independently associated with EnDys. There were no interactions for sex with 6MWT and WC. **Conclusion:** Among measures of fitness, PA, and fatness, and in both sexes, a lower walking distance and a higher waist circumference were each independently associated with a lower EnDys, indicating worse endothelial function. A next logical step is to assess if EnDys improves with interventions like exercise and weight loss, thereby providing a novel and relatively simple way to track progress towards CVD risk reduction.

PURPOSE: Hypertension affects more than 60% of older individuals and is associated with reduced baroreflex sensitivity (BRS). Lifestyle interventions, such as exercise, are recommended to promote healthy aging. Exercise training improves autonomic modulation and BRS in varied populations but not in patients with severe autonomic dysfunction. Due to the scarcity of the literature in the context of older adults with hypertension, we aimed to evaluate BRS and autonomic modulation of elders exposed to lifestyle interventions. Our hypothesis was that the exercise intervention would be superior to a health education program in improving these variables. **METHODS:** In a secondary outcome analysis of the HAEI Study (NCT03264443), 34 older adults (mean age 67.7 ± 7.0) with hypertension (mean blood pressure $142.3 \pm 22.5/78.8 \pm 12.6$ mm Hg) and in use of anti-hypertensive drugs were randomized to one of two 12-week interventions: EXERCISE (a 3 days/week⁻¹, moderate-intensity, 1h-long, combined exercise program based on walking/running and body-weight/elastic bands resistance exercises) and EDUCATION (a weekly health education program based on hypertension management). BRS, frequency-domain indexes

of blood pressure and heart rate variability and time-domain indexes of heart rate variability were calculated pre and post interventions through a continuous beat-to-beat blood pressure signal acquired with a sampling rate of 1000Hz.

RESULTS: Baseline values for BRS were 16.7 ± 5.3 ms.mm Hg⁻¹ for EDUCATION and 16.5 ± 9.3 ms.mm Hg⁻¹ for EXERCISE. BRS change from baseline and respective 95% confidence intervals were $+0.1$ (-4.7 to $+4.9$) ms.mm Hg⁻¹ for EDUCATION and $+1.4$ (-1.5 to $+4.4$) ms.mm Hg⁻¹ for EXERCISE ($P = 0.53$). No differences were found in frequency-domain indexes of blood pressure variability and heart rate and time-domain indexes of heart rate variability.

CONCLUSIONS: In elders with hypertension, no changes in BRS or autonomic control were induced by 12 weeks of either health education or exercise training. These subjects might present some degree of blunted responsiveness to interventions with characteristics similar to what we proposed in relation to autonomic control modulation.

ABSTRACT

Cardiovascular diseases are part of the highly preventable chronic diseases associated with changes in lifestyle. Within them, physical activity, low-fat & high-fiber diets are distinguished as the main support for prevention, even when supplementation with nutraceuticals has become a very common practice.

PURPOSE: A systematic physical exercise program and *Spirulina maxima* (*S. maxima*) intake have beneficial effects on general fitness and blood lipid profile in overweight and obese men. **METHODS:** Fifty-two young sedentary men with excess body weight (Body mass index [BMI] ≥ 25 kg·m⁻²) were enrolled in a randomized-crossover controlled trial [six weeks of a systematic physical exercise with *S. maxima* or placebo supplementation (4.5 g·day⁻¹)]. Maximal oxygen uptake (VO_{2max}), BMI, blood lipid profile (total cholesterol [TC], triglycerides [TG], low-density lipoproteins cholesterol [LDL-C], high-density lipoproteins cholesterol [HDL-C]), and their correlations were determined pre/post intervention. **RESULTS:** After the study, obese subjects showed statistical differences ($p < 0.01$, basal vs. final) in BMI (33.3 ± 3.8 vs. 30.1 ± 4.9 kg·m⁻²), VO_{2max} (30.8 ± 5.6 vs. 34.7 ± 6.2 mL·min⁻¹·kg⁻¹), and blood lipids (mg·dL⁻¹): TC (218 ± 30 vs. 184 ± 33), TG (150 ± 46 vs. 127 ± 35), LDL-C (158 ± 31 vs. 122 ± 34), and HDL-C (32.5 ± 10.9 vs. 38.6 ± 9.6). Moreover, according to the correlation analysis ($p < 0.01$), in the exercise and *S. maxima* supplementation group, BMI decrease as VO_{2max} increase ($r = -0.492$), TC and LDL-C decrease linearly ($r = -0.798$), finally, while LDL-C levels decrease, HDL-C increases ($r = -0.690$). **CONCLUSION:** These results indicate that the *S. maxima* supplementation could be acting in a synergistic way with exercise due to the enhanced effects on body composition, cardiorespiratory fitness, and blood lipid profile, this phenomenon should be considered to reduce risk of cardiovascular disorders.

The study protocol was approved by the Autonomous University of Ciudad Juarez review board (Bioethics Committee Code: CBE.ICB/062.09-15) and carried out following the declaration of Helsinki, and the trial was registered at clinicaltrials.gov (Trial ID: NCT02837666).

Exercise in older adults results in very important benefits to health and quality of life. Low cardiorespiratory capacity, high cholesterol (HCHOL) and high triglycerides (HTRIG) are three of the mayor risk factors for cardiovascular diseases that can be improved with regular exercise.

PURPOSE: Would regular exercise (RE) and detraining (DT) promote different effects in total cholesterol, triglycerides and cardiorespiratory capacity of older women with or without lipid disorders (HCHOL and HTRIG)?

METHODS: Seventeen older women with HCHOL and HTRIG were recruited for the lipid disorder group (LDG) and twenty-three older women without HCHOL and HTRIG were recruited for the no lipid disorder group (CG) (LDG: n = 17, 68.7 ± 2.1 years; CG: n = 23, 69.4 ± 3.7 years). Booth groups followed a nine-month multicomponent exercise program before a three-month detraining period. Cardiorespiratory capacity was assessed through 6-min walk test (6MWT), and total cholesterol (TCHOL) and triglycerides (TG) blood sample were assessed in accordance with the procedures of Diabetes Atlas Committee. All assessments were conducted before and after the exercise program and after three months of detraining. Mixed-model ANOVA was used to examine differences within and between groups.

RESULTS: In booth groups RE promoted declines in TCHOL (LDG: -7.93%, $p < 0.01$; CG: -9.12%, $p < 0.01$), TG (LDG: -10.89%, $p < 0.01$; CG: -11.14%, $p < 0.01$) and 6MWT (LDG: 10.87%, $p < 0.01$; CG: 12.39%, $p < 0.01$), and DT led to negative effects on TCHOL (LDG: 5.81%, $p < 0.01$; CG: 7.8%, $p < 0.01$) and TG (LDG: 9.41%, $p < 0.01$; CG: 9.07%, $p < 0.01$), and 6MWT (LDG: -4.78%, $p < 0.01$; CG: -6.20%, $p < 0.01$).

CONCLUSIONS: Three months of DT are enough to reverse the benefits of exercise in TCHOL of non-lipid disorder older women, and regular exercise in older women with lipid disorders promotes benefits in cardiorespiratory capacity, TG and TCHOL with lower impact compared to older women without this disorders but are strong enough to be retained after three months of DT.
